{AI12-0112-1} function Next_Sibling (Position : Cursor) return Cursor
   with Nonblocking, Global => in all, Use_Formal => null,
        Post => (if Position = No_Element
                    then Next_Sibling'Result = No_Element);
```

203/3 {*AI05-0136-1*} If Position equals No_Element or designates the last child node of its parent, then Next_Sibling returns the value No_Element. Otherwise, it returns a cursor that designates the successor (with the same parent) of the node designated by Position.

203.1/5
```
function Next_Sibling (Container : Tree;
                       Position  : Cursor) return Cursor
   with Nonblocking, Global => null, Use_Formal => null,
        Pre  => Meaningful_For (Container, Position)
                   or else raise Program_Error,
        Post => (if Next_Sibling'Result = No_Element then
                   Position = No_Element or else
                   Is_Root (Container, Position) or else
                   Last_Child (Container, Parent (Container, Position))
                      = Position
                 else Has_Element (Container, Next_Sibling'Result));
```

203.2/5 {*AI12-0112-1*} Next_Sibling returns a cursor that designates the successor (with the same parent) of the node designated by Position in Container.

204/5
```
{AI12-0112-1} function Previous_Sibling (Position : in out Cursor)
   with Nonblocking, Global => in all, Use_Formal => null,
        Post => (if Position = No_Element
                    then Previous_Sibling'Result = No_Element);
```

205/3 {*AI05-0136-1*} If Position equals No_Element or designates the first child node of its parent, then Previous_Sibling returns the value No_Element. Otherwise, it returns a cursor that designates the predecessor (with the same parent) of the node designated by Position.

205.1/5
```
function Previous_Sibling (Container : Tree;
                           Position  : Cursor) return Cursor
   with Nonblocking, Global => null, Use_Formal => null,
        Pre  => Meaningful_For (Container, Position)
                   or else raise Program_Error,
        Post => (if Previous_Sibling'Result = No_Element then
                   Position = No_Element or else
                   Is_Root (Container, Position) or else
                   First_Child (Container, Parent (Container, Position))
                      = Position
                 else Has_Element (Container, Previous_Sibling'Result));
```

        Pre  => Parent /= No_Element or else raise Constraint_Error,
        Global => in all, Use_Formal => null;
```

This paragraph was deleted.{*AI05-0136-1*} {*AI05-0248-1*} {*AI12-0112-1*} 215/5

216/3 Reverse_Iterate_Children calls Process.**all** with a cursor that designates each child node of Parent, starting with the last child node and moving the cursor as per the Previous_Sibling function.

217/3 {*AI05-0265-1*} Tampering with the cursors of the tree containing Parent is prohibited during the execution of a call on Process.**all**. Any exception raised by Process.**all** is propagated.

217.1/5
```
{AI12-0112-1} procedure Reverse_Iterate_Children
     (Container : in Tree;
      Parent    : in Cursor;
      Process   : not null access procedure (Position : in Cursor))
   with Allows_Exit,
        Pre  => (Parent /= No_Element
                   or else raise Constraint_Error) and then
                (Meaningful_For (Container, Parent)
                   or else raise Program_Error);
```

217.2/5 {*AI12-0112-1*} Reverse_Iterate_Children calls Process.**all** with a cursor that designates each child node of Container and Parent, starting with the last child node and moving the cursor as per the Previous_Sibling function.

217.3/5 {*AI12-0112-1*} Tampering with the cursors of the tree containing Parent is prohibited during the execution of a call on Process.**all**. Any exception raised by Process.**all** is propagated.

218/5
```
function Iterate_Children (Container : in Tree; Parent : in Cursor)
   return Tree_Iterator_Interfaces.Parallel_Reversible_Iterator'Class
   with Pre  => (Parent /= No_Element
                   or else raise Constraint_Error) and then
                (Meaningful_For (Container, Parent)
                   or else raise Program_Error),
        Post => Tampering_With_Cursors_Prohibited (Container);
```

219/5 {*AI05-0212-1*} {*AI05-0265-1*} {*AI12-0112-1*} {*AI12-0266-1*} Iterate_Children returns an iterator object (see 5.5.1) that will generate a value for a loop parameter (see 5.5.2) designating each child node of Parent. When used as a forward iterator, the nodes are designated starting with the first child node and moving the cursor as per the function Next_Sibling; when used as a reverse iterator, the nodes are designated starting with the last child node and moving the cursor as per the function Previous_Sibling; when used as a parallel iterator, processing all child nodes concurrently. Tampering with the cursors of Container is prohibited while the iterator object exists (in particular, in the sequence_of_statements of the loop_statement whose iterator_specification denotes this object). The iterator object needs finalization.

219.1/5 {*AI12-0111-1*} The nested package Multiway_Trees.Stable provides a type Stable.Tree that represents a *stable* tree, which is one that cannot grow and shrink. Such a tree can be created by calling the Copy function, or by establishing a *stabilized view* of an ordinary tree.

219.2/5 {*AI12-0111-1*} The subprograms of package Containers.Multiway_Trees that have a parameter or result of type tree are included in the nested package Stable with the same specification, except that the following are omitted:

219.3/5 Tampering_With_Cursors_Prohibited, Tampering_With_Elements_Prohibited, Assign, Move, Clear, Delete_Leaf, Insert_Child, Delete_Children, Delete_Subtree, Copy_Subtree, Copy_Local_Subtree, Splice_Subtree, and Splice_Children

219.a.1/5 **Ramification:** The names Tree and Cursor mean the types declared in the nested package in these subprogram specifications.

219.a.2/5 **Reason:** The omitted routines are those that tamper with cursors or elements (or test that state). The model is that it is impossible to tamper with cursors or elements of a stable view since no such operations are included. Thus tampering checks are not needed for a stable view, and we omit the operations associated with those checks.

{*AI12-0111-1*} The operations of this package are equivalent to those for ordinary trees, except that the calls to Tampering_With_Cursors_Prohibited and Tampering_With_Elements_Prohibited that occur in preconditions are replaced by False, and any that occur in postconditions are replaced by True. 219.4/5

{*AI12-0111-1*} {*AI12-0439-1*} If a stable tree is declared with the Base discriminant designating a pre-existing ordinary tree, the stable tree represents a stabilized view of the underlying ordinary tree, and any operation on the stable tree is reflected on the underlying ordinary tree. While a stabilized view exists, any operation that tampers with elements performed on the underlying tree is prohibited. The finalization of a stable tree that provides such a view removes this restriction on the underlying ordinary tree [(though some other restriction can exist due to other concurrent iterations or stabilized views)]. 219.5/5

{*AI12-0111-1*} {*AI12-0438-1*} If a stable tree is declared without specifying Base, the object is necessarily initialized. The initializing expression of the stable tree, [typically a call on Copy], determines the Node_Count of the tree. The Node_Count of a stable tree never changes after initialization. 219.6/5

Proof: {*AI12-0438-1*} Initialization is required as the type is indefinite, see 3.3.1. 219.a/5

Bounded (Run-Time) Errors

{*AI05-0136-1*} {*AI05-0248-1*} It is a bounded error for the actual function associated with a generic formal subprogram, when called as part of an operation of this package, to tamper with elements of any Tree parameter of the operation. Either Program_Error is raised, or the operation works as defined on the value of the Tree either prior to, or subsequent to, some or all of the modifications to the Tree. 220/3

{*AI05-0136-1*} It is a bounded error to call any subprogram declared in the visible part of Containers.Multiway_Trees when the associated container has been finalized. If the operation takes Container as an **in out** parameter, then it raises Constraint_Error or Program_Error. Otherwise, the operation either proceeds as it would for an empty container, or it raises Constraint_Error or Program_Error. 221/3

Erroneous Execution

{*AI05-0136-1*} A Cursor value is *invalid* if any of the following have occurred since it was created: 222/3

- The tree that contains the element it designates has been finalized; 223/3
- The tree that contains the element it designates has been used as the Source or Target of a call to Move; 224/3
- The tree that contains the element it designates has been used as the Target of a call to Assign or the target of an assignment_statement; 225/3
- The element it designates has been removed from the tree that previously contained the element. 226/3

Reason: We talk about which tree the element was removed from in order to handle splicing nodes from one tree to another. The node still exists, but any cursors that designate it in the original tree are now invalid. This bullet covers removals caused by calls to Clear, Delete_Leaf, Delete_Subtree, Delete_Children, Splice_Children, and Splice_Subtree. 226.a/3

The result of "=" or Has_Element is unspecified if it is called with an invalid cursor parameter. Execution is erroneous if any other subprogram declared in Containers.Multiway_Trees is called with an invalid cursor parameter. 227/3

Discussion: The list above is intended to be exhaustive. In other cases, a cursor value continues to designate its original element (or the root node). For instance, cursor values survive the insertion and deletion of other nodes. 227.a/3

While it is possible to check for these cases, in many cases the overhead necessary to make the check is substantial in time or space. Implementations are encouraged to check for as many of these cases as possible and raise Program_Error if detected. 227.b/3

228/3 {*AI05-0212-1*} Execution is erroneous if the tree associated with the result of a call to Reference or Constant_Reference is finalized before the result object returned by the call to Reference or Constant_Reference is finalized.

228.a/3 **Reason:** Each object of Reference_Type and Constant_Reference_Type probably contains some reference to the originating container. If that container is prematurely finalized (which is only possible via Unchecked_Deallocation, as accessibility checks prevent passing a container to Reference that will not live as long as the result), the finalization of the object of Reference_Type will try to access a nonexistent object. This is a normal case of a dangling pointer created by Unchecked_Deallocation; we have to explicitly mention it here as the pointer in question is not visible in the specification of the type. (This is the same reason we have to say this for invalid cursors.)

Implementation Requirements

229/3 {*AI05-0136-1*} No storage associated with a multiway tree object shall be lost upon assignment or scope exit.

230/3 {*AI05-0136-1*} {*AI05-0262-1*} The execution of an assignment_statement for a tree shall have the effect of copying the elements from the source tree object to the target tree object and changing the node count of the target object to that of the source object.

230.a/3 **Implementation Note:** {*AI05-0298-1*} An assignment of a Tree is a "deep" copy; that is the elements are copied as well the data structures. We say "effect of" in order to allow the implementation to avoid copying elements immediately if it wishes. For instance, an implementation that avoided copying until one of the containers is modified would be allowed. (Note that this implementation would require care, see A.18.2 for more.)

Implementation Advice

231/3 {*AI05-0136-1*} Containers.Multiway_Trees should be implemented similarly to a multiway tree. In particular, if *N* is the overall number of nodes for a particular tree, then the worst-case time complexity of Element, Parent, First_Child, Last_Child, Next_Sibling, Previous_Sibling, Insert_Child with Count=1, and Delete should be $O(\log N)$.

231.a/3 **Implementation Advice:** The worst-case time complexity of the Element, Parent, First_Child, Last_Child, Next_Sibling, Previous_Sibling, Insert_Child with Count=1, and Delete operations of Containers.Multiway_Trees should be $O(\log N)$.

231.b/3 **Reason:** We do not mean to overly constrain implementation strategies here. However, it is important for portability that the performance of large containers has roughly the same factors on different implementations. If a program is moved to an implementation that takes $O(N)$ time to access elements, that program could be unusable when the trees are large. We allow $O(\log N)$ access because the proportionality constant and caching effects are likely to be larger than the log factor, and we don't want to discourage innovative implementations.

232/3 {*AI05-0136-1*} Move should not copy elements, and should minimize copying of internal data structures.

232.a/3 **Implementation Advice:** Containers.Multiway_Trees.Move should not copy elements, and should minimize copying of internal data structures.

232.b/3 **Implementation Note:** Usually that can be accomplished simply by moving the pointer(s) to the internal data structures from the Source container to the Target container.

233/3 {*AI05-0136-1*} If an exception is propagated from a tree operation, no storage should be lost, nor any elements removed from a tree unless specified by the operation.

233.a/3 **Implementation Advice:** If an exception is propagated from a tree operation, no storage should be lost, nor any elements removed from a tree unless specified by the operation.

233.b/3 **Reason:** This is important so that programs can recover from errors. But we don't want to require heroic efforts, so we just require documentation of cases where this can't be accomplished.

Extensions to Ada 2005

233.c/3 {*AI05-0136-1*} {*AI05-0257-1*} {*AI05-0265-1*} {*AI05-0269-1*} The generic package Containers.Multiway_Trees is new.

Inconsistencies With Ada 2012

{*AI12-0111-1*} **Correction:** Tampering with elements is now defined to be equivalent to tampering with cursors for ordinary containers. If a program requires tampering detection to work, it might fail in Ada 2022. Needless to say, this shouldn't happen outside of test programs. See Inconsistencies With Ada 2012 in A.18.2 for more details. 233.d/5

Incompatibilities With Ada 2012

{*AI12-0111-1*} {*AI12-0112-1*} A number of new subprograms, types, and even a nested package were added to Containers.Multiway_Trees to better support contracts and stable views. Therefore, a use clause conflict is possible; see the introduction of Annex A for more on this topic. 233.e/5

Extensions to Ada 2012

{*AI12-0196-1*} **Correction:** Replace_Element is now defined such that it can be used concurrently so long as it operates on different elements. This allows some container operations to be used in parallel without separate synchronization. 233.f/5

{*AI12-0266-1*} Most iterators can now return parallel iterators, to be used in parallel constructs. 233.g/5

Wording Changes from Ada 2012

{*AI12-0069-1*} **Corrigendum:** Fixed the function Iterate so it is clear that the root node is never visited. 233.h/4

{*AI12-0078-1*} **Corrigendum:** The definition of *node* is clarified so that it it doesn't appear to say all nodes have an element. 233.i/4

{*AI12-0110-1*} **Corrigendum:** Clarified that tampering checks precede all other checks made by a subprogram (but come after those associated with the call). 233.j/4

{*AI12-0112-1*} Added contracts to this container. This includes describing some of the semantics with pre- and postconditions, rather than English text. Note that the preconditions can be Suppressed (see 11.5). 233.k/5

A.18.11 The Generic Package Containers.Indefinite_Vectors

{*AI95-00302-03*} The language-defined generic package Containers.Indefinite_Vectors provides a private type Vector and a set of operations. It provides the same operations as the package Containers.Vectors (see A.18.2), with the difference that the generic formal Element_Type is indefinite. 1/2

Static Semantics

{*AI95-00302-03*} {*AI05-0092-1*} The declaration of the generic library package Containers.Indefinite_Vectors has the same contents and semantics as Containers.Vectors except: 2/3

- The generic formal Element_Type is indefinite. 3/2
- The procedures with the profiles: 4/2

```
procedure Insert (Container : in out Vector;                    5/2
                  Before    : in     Extended_Index;
                  Count     : in     Count_Type := 1);
procedure Insert (Container : in out Vector;                    6/2
                  Before    : in     Cursor;
                  Position  :    out Cursor;
                  Count     : in     Count_Type := 1);
```

  are omitted. 7/2

  Discussion: These procedures are omitted because there is no way to create a default-initialized object of an indefinite type. Note that Insert_Space can be used instead of this routine in most cases. Omitting the routine completely allows any problems to be diagnosed by the compiler when converting from a definite to indefinite vector. 7.a/2

- The actual Element parameter of access subprogram Process of Update_Element may be constrained even if Element_Type is unconstrained. 8/2
- {*AI12-0035-1*} The operations "&", Append, Insert, Prepend, Replace_Element, and To_Vector that have a formal parameter of type Element_Type perform indefinite insertion (see A.18). 9/4

10/5 • {*AI12-0111-1*} {*AI12-0112-1*} The description of Tampering_With_Elements_Prohibited is replaced by:

11/5 Returns True if tampering with elements is prohibited for Container, and False otherwise.

11.a/5 **Reason:** Complete replacement of an element can cause its memory to be deallocated while another operation is holding onto a reference to it. That can't be allowed. However, a simple modification of (part of) an element is not a problem, so Update_Element does not cause a problem.

12/5 • {*AI12-0111-1*} {*AI12-0112-1*} Tampering_With_Cursors_Prohibited is replaced by Tampering_With_Elements_Prohibited in the postcondition for the operations Reference and Constant_Reference.

13/5 • {*AI12-0111-1*} The operations Replace_Element, Reverse_Elements, and Swap, and the nested generic unit Generic_Sorting are omitted from the nested package Stable.

Extensions to Ada 95

13.a/2 {*AI95-00302-03*} The generic package Containers.Indefinite_Vectors is new.

Inconsistencies With Ada 2012

13.b/4 {*AI12-0035-1*} **Corrigendum:** Defined some routines to "perform indefinite insertion". This could mean that some calls to those routines would now raise Program_Error where they previously worked. However, this is extremely unlikely, as it would require that the package was not implemented in Ada (an Ada allocator would raise Program_Error in these circumstances), and that a program inserted a more nested tagged type (or access discriminant) into a container, and then used that object before its type or discriminant went out of scope. All known implementations are implemented in Ada, so we believe there is no practical incompatibility. As such, we mention this only for completeness.

13.c/5 {*AI12-0111-1*} Defined the Iterator_View aspect, so that the stable view is used for container element iterators. This means that tampering with elements is prohibited during the entire loop, rather than tampering with cursors being prohibited during the loop, and tampering with elements being prohibited only during the lifetimes of references to the loop parameter. Thus, if a container element iterator does an operation that tampers with elements on the iterated container, that operation will fail a tampering check in Ada 2022 (and thus raise Program_Error), while it would have worked in Ada 2012 so long as the loop parameter is not involved. We believe this to be a dubious loop structure that should be rare. Note that this issue only occurs for the indefinite container form, the ordinary and bounded containers allow such operations at any time in Ada 2022.

A.18.12 The Generic Package Containers.Indefinite_Doubly_Linked_Lists

1/2 {*AI95-00302-03*} The language-defined generic package Containers.Indefinite_Doubly_Linked_Lists provides private types List and Cursor, and a set of operations for each type. It provides the same operations as the package Containers.Doubly_Linked_Lists (see A.18.3), with the difference that the generic formal Element_Type is indefinite.

Static Semantics

2/3 {*AI95-00302-03*} {*AI05-0092-1*} The declaration of the generic library package Containers.Indefinite_-Doubly_Linked_Lists has the same contents and semantics as Containers.Doubly_Linked_Lists except:

3/2 • The generic formal Element_Type is indefinite.

4/2 • The procedure with the profile:

5/2
```
procedure Insert (Container : in out List;
                  Before    : in     Cursor;
                  Position  :    out Cursor;
                  Count     : in     Count_Type := 1);
```

6/2 is omitted.

6.a/2 **Discussion:** This procedure is omitted because there is no way to create a default-initialized object of an indefinite type. We considered having this routine insert an empty element similar to the empty elements of a vector, but rejected

this possibility because the semantics are fairly complex and very different from the existing definite container. That would make it more error-prone to convert a container from a definite type to an indefinite type; by omitting the routine completely, any problems will be diagnosed by the compiler.

- The actual Element parameter of access subprogram Process of Update_Element may be constrained even if Element_Type is unconstrained. 7/2
- {*AI12-0035-1*} The operations Append, Insert, Prepend, and Replace_Element that have a formal parameter of type Element_Type perform indefinite insertion (see A.18). 8/4
- {*AI12-0111-1*} {*AI12-0112-1*} The description of Tampering_With_Elements_Prohibited is replaced by: 9/5

  Returns True if tampering with elements is prohibited for Container, and False otherwise. 10/5

  Reason: Complete replacement of an element can cause its memory to be deallocated while another operation is holding onto a reference to it. That can't be allowed. However, a simple modification of (part of) an element is not a problem. 10.a/5
- {*AI12-0111-1*} {*AI12-0112-1*} Tampering_With_Cursors_Prohibited is replaced by Tampering_With_Elements_Prohibited in the postcondition for the operations Reference and Constant_Reference. 11/5
- {*AI12-0111-1*} The operations Replace_Element and Swap are omitted from the nested package Stable. 12/5

Extensions to Ada 95

{*AI95-00302-03*} The generic package Containers.Indefinite_Doubly_Linked_Lists is new. 12.a/2

Inconsistencies With Ada 2012

{*AI12-0035-1*} **Corrigendum:** Defined some routines to "perform indefinite insertion". This could mean that some calls to those routines would now raise Program_Error where they previously worked. However, this is extremely unlikely; see Inconsistencies With Ada 2012 in A.18.11 for details. 12.b/4

{*AI12-0111-1*} Defined the Iterator_View aspect, so that the stable view is used for container element iterators. This leads to a rare situation where Program_Error will be raised in Ada 2022 for code that would have worked in Ada 2012. See Inconsistencies With Ada 2012 in A.18.11 for details. 12.c/5

A.18.13 The Generic Package Containers.Indefinite_Hashed_Maps

{*AI95-00302-03*} The language-defined generic package Containers.Indefinite_Hashed_Maps provides a map with the same operations as the package Containers.Hashed_Maps (see A.18.5), with the difference that the generic formal types Key_Type and Element_Type are indefinite. 1/2

Static Semantics

{*AI95-00302-03*} {*AI05-0092-1*} The declaration of the generic library package Containers.Indefinite_Hashed_Maps has the same contents and semantics as Containers.Hashed_Maps except: 2/3

- The generic formal Key_Type is indefinite. 3/2
- The generic formal Element_Type is indefinite. 4/2
- The procedure with the profile: 5/2

```
procedure Insert (Container : in out Map;                    6/2
                  Key       : in     Key_Type;
                  Position  :    out Cursor;
                  Inserted  :    out Boolean);
```

  is omitted. 7/2

  Discussion: This procedure is omitted because there is no way to create a default-initialized object of an indefinite type. We considered having this routine insert an empty element similar to the empty elements of a vector, but rejected 7.a/2

this possibility because the semantics are fairly complex and very different from the existing case. That would make it more error-prone to convert a container from a definite type to an indefinite type; by omitting the routine completely, any problems will be diagnosed by the compiler.

8/2 • The actual Element parameter of access subprogram Process of Update_Element may be constrained even if Element_Type is unconstrained.

9/4 • {*AI12-0035-1*} The operations Include, Insert, Replace, and Replace_Element that have a formal parameter of type Element_Type perform indefinite insertion (see A.18).

9.a/4 **Discussion:** Some of the named operations also have a formal of the indefinite formal type Key_Type and perform indefinite insertion using that value, but it is sufficient to mention the formal of type Element_Type to cover those.

10/5 • {*AI12-0111-1*} {*AI12-0112-1*} The description of Tampering_With_Elements_Prohibited is replaced by:

11/5 Returns True if tampering with elements is prohibited for Container, and False otherwise.

11.a/5 **Reason:** Complete replacement of an element can cause its memory to be deallocated while another operation is holding onto a reference to it. That can't be allowed. However, a simple modification of (part of) an element is not a problem.

12/5 • {*AI12-0111-1*} {*AI12-0112-1*} Tampering_With_Cursors_Prohibited is replaced by Tampering_With_Elements_Prohibited in the postcondition for the operations Reference and Constant_Reference.

13/5 • {*AI12-0111-1*} The operations Replace and Replace_Element are omitted from the nested package Stable.

Extensions to Ada 95

13.a/2 {*AI95-00302-03*} The generic package Containers.Indefinite_Hashed_Maps is new.

Inconsistencies With Ada 2012

13.b/4 {*AI12-0035-1*} **Corrigendum:** Defined some routines to “perform indefinite insertion”. This could mean that some calls to those routines would now raise Program_Error where they previously worked. However, this is extremely unlikely; see Inconsistencies With Ada 2012 in A.18.11 for details.

13.c/5 {*AI12-0111-1*} Defined the Iterator_View aspect, so that the stable view is used for container element iterators. This leads to a rare situation where Program_Error will be raised in Ada 2022 for code that would have worked in Ada 2012. See Inconsistencies With Ada 2012 in A.18.11 for details.

A.18.14 The Generic Package Containers.Indefinite_Ordered_Maps

1/2 {*AI95-00302-03*} The language-defined generic package Containers.Indefinite_Ordered_Maps provides a map with the same operations as the package Containers.Ordered_Maps (see A.18.6), with the difference that the generic formal types Key_Type and Element_Type are indefinite.

Static Semantics

2/3 {*AI95-00302-03*} {*AI05-0092-1*} The declaration of the generic library package Containers.Indefinite_Ordered_Maps has the same contents and semantics as Containers.Ordered_Maps except:

3/2 • The generic formal Key_Type is indefinite.

4/2 • The generic formal Element_Type is indefinite.

5/2 • The procedure with the profile:

6/2
```
procedure Insert (Container : in out Map;
                  Key       : in     Key_Type;
                  Position  :    out Cursor;
                  Inserted  :    out Boolean);
```

7/2 is omitted.

Discussion: This procedure is omitted because there is no way to create a default-initialized object of an indefinite type. We considered having this routine insert an empty element similar to the empty elements of a vector, but rejected this possibility because the semantics are fairly complex and very different from the existing case. That would make it more error-prone to convert a container from a definite type to an indefinite type; by omitting the routine completely, any problems will be diagnosed by the compiler. 7.a/2

- The actual Element parameter of access subprogram Process of Update_Element may be constrained even if Element_Type is unconstrained. 8/2
- {*AI12-0035-1*} The operations Include, Insert, Replace, and Replace_Element that have a formal parameter of type Element_Type perform indefinite insertion (see A.18). 9/4

  Discussion: Some of the named operations also have a formal of the indefinite formal type Key_Type and perform indefinite insertion using that value, but it is sufficient to mention the formal of type Element_Type to cover those. 9.a/4
- {*AI12-0111-1*} {*AI12-0112-1*} The description of Tampering_With_Elements_Prohibited is replaced by: 10/5

  Returns True if tampering with elements is prohibited for Container, and False otherwise. 11/5

  Reason: Complete replacement of an element can cause its memory to be deallocated while another operation is holding onto a reference to it. That can't be allowed. However, a simple modification of (part of) an element is not a problem. 11.a/5
- {*AI12-0111-1*} {*AI12-0112-1*} Tampering_With_Cursors_Prohibited is replaced by Tampering_With_Elements_Prohibited in the postcondition for the operations Reference and Constant_Reference. 12/5
- {*AI12-0111-1*} The operations Replace and Replace_Element are omitted from the nested package Stable. 13/5

Extensions to Ada 95

{*AI95-00302-03*} The generic package Containers.Indefinite_Ordered_Maps is new. 13.a/2

Inconsistencies With Ada 2012

{*AI12-0035-1*} **Corrigendum:** Defined some routines to “perform indefinite insertion”. This could mean that some calls to those routines would now raise Program_Error where they previously worked. However, this is extremely unlikely; see Inconsistencies With Ada 2012 in A.18.11 for details. 13.b/4

{*AI12-0111-1*} Defined the Iterator_View aspect, so that the stable view is used for container element iterators. This leads to a rare situation where Program_Error will be raised in Ada 2022 for code that would have worked in Ada 2012. See Inconsistencies With Ada 2012 in A.18.11 for details. 13.c/5

A.18.15 The Generic Package Containers.Indefinite_Hashed_Sets

{*AI95-00302-03*} The language-defined generic package Containers.Indefinite_Hashed_Sets provides a set with the same operations as the package Containers.Hashed_Sets (see A.18.8), with the difference that the generic formal type Element_Type is indefinite. 1/2

Static Semantics

{*AI95-00302-03*} {*AI05-0092-1*} The declaration of the generic library package Containers.Indefinite_Hashed_Sets has the same contents and semantics as Containers.Hashed_Sets except: 2/3

- The generic formal Element_Type is indefinite. 3/2
- The actual Element parameter of access subprogram Process of Update_Element_Preserving_Key may be constrained even if Element_Type is unconstrained. 4/2
- {*AI12-0035-1*} The operations Include, Insert, Replace, Replace_Element, and To_Set that have a formal parameter of type Element_Type perform indefinite insertion (see A.18). 5/4

5.a/4 **Ramification:** This includes the procedure Replace declared in the nested generic package Generic_Keys, as well as the routines declared directly in the Containers.Indefinite_Hashed_Sets package.

5.b/5 **Discussion:** {*AI12-0111-1*} Unlike the other containers, a Hashed_Set has no operations that tamper with elements without tampering with cursors. Modifying the contents of a element of a set can change its position in the set, so those operations tamper with cursors.

5.c/5 {*AI12-0111-1*} Because of this characteristic, this subclause is missing the rules that other indefinite containers have modifying the definition and use of Tampering_with_Elements, and the definition of the Stable subpackaage is the same as the definite version.

Extensions to Ada 95

5.d/2 {*AI95-00302-03*} The generic package Containers.Indefinite_Hashed_Sets is new.

Inconsistencies With Ada 2012

5.e/4 {*AI12-0035-1*} **Corrigendum:** Defined some routines to "perform indefinite insertion". This could mean that some calls to those routines would now raise Program_Error where they previously worked. However, this is extremely unlikely; see Inconsistencies With Ada 2012 in A.18.11 for details.

A.18.16 The Generic Package Containers.Indefinite_Ordered_Sets

1/2 {*AI95-00302-03*} The language-defined generic package Containers.Indefinite_Ordered_Sets provides a set with the same operations as the package Containers.Ordered_Sets (see A.18.9), with the difference that the generic formal type Element_Type is indefinite.

Static Semantics

2/3 {*AI95-00302-03*} {*AI05-0092-1*} The declaration of the generic library package Containers.Indefinite_Ordered_Sets has the same contents and semantics as Containers.Ordered_Sets except:

3/2 - The generic formal Element_Type is indefinite.

4/2 - The actual Element parameter of access subprogram Process of Update_Element_Preserving_Key may be constrained even if Element_Type is unconstrained.

5/4 - {*AI12-0035-1*} The operations Include, Insert, Replace, Replace_Element, and To_Set that have a formal parameter of type Element_Type perform indefinite insertion (see A.18).

5.a/4 **Ramification:** This includes the procedure Replace declared in the nested generic package Generic_Keys, as well as the routines declared directly in the Containers.Indefinite_Ordered_Sets package.

5.b/5 **Discussion:** {*AI12-0111-1*} Unlike the other containers, a Ordered_Set has no operations that tamper with elements without tampering with cursors. Modifying the contents of a element of a set can change its position in the set, so those operations tamper with cursors.

5.c/5 {*AI12-0111-1*} Because of this characteristic, this subclause is missing the rules that other indefinite containers have modifying the definition and use of Tampering_with_Elements, and the definition of the Stable subpackaage is the same as the definite version.

Extensions to Ada 95

5.d/2 {*AI95-00302-03*} The generic package Containers.Indefinite_Ordered_Sets is new.

Inconsistencies With Ada 2012

5.e/4 {*AI12-0035-1*} **Corrigendum:** Defined some routines to "perform indefinite insertion". This could mean that some calls to those routines would now raise Program_Error where they previously worked. However, this is extremely unlikely; see Inconsistencies With Ada 2012 in A.18.11 for details.

A.18.17 The Generic Package Containers.Indefinite_Multiway_Trees

{*AI05-0136-1*} The language-defined generic package Containers.Indefinite_Multiway_Trees provides a multiway tree with the same operations as the package Containers.Multiway_Trees (see A.18.10), with the difference that the generic formal Element_Type is indefinite. 1/3

Static Semantics

{*AI05-0136-1*} The declaration of the generic library package Containers.Indefinite_Multiway_Trees has the same contents and semantics as Containers.Multiway_Trees except: 2/3

- The generic formal Element_Type is indefinite. 3/3
- The procedure with the profile: 4/3

```
procedure Insert_Child (Container : in out Tree;                    5/3
                        Parent    : in     Cursor;
                        Before    : in     Cursor;
                        Position  :    out Cursor;
                        Count     : in     Count_Type := 1);
```

  is omitted. 6/3

  Discussion: This procedure is omitted because there is no way to create a default-initialized object of an indefinite type. We considered having this routine insert an empty element similar to the empty elements of a vector, but rejected this possibility because the semantics are fairly complex and very different from the existing case. That would make it more error-prone to convert a container from a definite type to an indefinite type; by omitting the routine completely, any problems will be diagnosed by the compiler. 6.a/3

- The actual Element parameter of access subprogram Process of Update_Element may be constrained even if Element_Type is unconstrained. 7/3
- {*AI12-0035-1*} The operations Append_Child, Insert_Child, Prepend_Child, and Replace_Element that have a formal parameter of type Element_Type perform indefinite insertion (see A.18). 8/4
- {*AI12-0111-1*} {*AI12-0112-1*} The description of Tampering_With_Elements_Prohibited is replaced by: 9/5

  Returns True if tampering with elements is prohibited for Container, and False otherwise. 10/5

  Reason: Complete replacement of an element can cause its memory to be deallocated while another operation is holding onto a reference to it. That can't be allowed. However, a simple modification of (part of) an element is not a problem. 10.a/5
- {*AI12-0111-1*} {*AI12-0112-1*} Tampering_With_Cursors_Prohibited is replaced by Tampering_With_Elements_Prohibited in the postcondition for the operations Reference and Constant_Reference. 11/5
- {*AI12-0111-1*} The operations Replace_Element and Swap are omitted from the nested package Stable. 12/5

Extensions to Ada 2005

{*AI05-0136-1*} The generic package Containers.Indefinite_Multiway_Trees is new. 12.a/3

Inconsistencies With Ada 2012

{*AI12-0035-1*} **Corrigendum:** Defined some routines to “perform indefinite insertion”. This could mean that some calls to those routines would now raise Program_Error where they previously worked. However, this is extremely unlikely; see Inconsistencies With Ada 2012 in A.18.11 for details. 12.b/4

{*AI12-0111-1*} Defined the Iterator_View aspect, so that the stable view is used for container element iterators. This leads to a rare situation where Program_Error will be raised in Ada 2022 for code that would have worked in Ada 2012. See Inconsistencies With Ada 2012 in A.18.11 for details. 12.c/5

A.18.18 The Generic Package Containers.Indefinite_Holders

1/3 {*AI05-0069-1*} The language-defined generic package Containers.Indefinite_Holders provides a private type Holder and a set of operations for that type. A holder container holds a single element of an indefinite type.

2/3 {*AI05-0069-1*} A holder container allows the declaration of an object that can be used like an uninitialized variable or component of an indefinite type.

3/3 {*AI05-0069-1*} A holder container may be *empty*. An empty holder does not contain an element.

Static Semantics

4/3 {*AI05-0069-1*} The generic library package Containers.Indefinite_Holders has the following declaration:

5/5
```
{AI05-0069-1} {AI05-0084-1} {AI12-0112-1} generic
   type Element_Type (<>) is private;
   with function "=" (Left, Right : Element_Type) return Boolean is <>;
package Ada.Containers.Indefinite_Holders
   with Preelaborate, Remote_Types,
        Nonblocking, Global => in out synchronized is
```

5.a/5 **Discussion:** {*AI12-0112-1*} For discussion on the reasons and meaning of the specifications of the Global and Nonblocking aspects in this generic package, see the notes on the equivalent operations in the specification of the Containers.Vectors package (see A.18.2).

6/5
```
   {AI12-0112-1} {AI12-0399-1}    type Holder is tagged private
         with Stable_Properties => (Is_Empty,
                                    Tampering_With_The_Element_Prohibited),
              Default_Initial_Condition => Is_Empty (Holder),
              Preelaborable_Initialization;
```

7/3
```
      Empty_Holder : constant Holder;
```

7.1/5
```
   {AI12-0112-1}    function Equal_Element (Left, Right : Element_Type) return Boolean
         renames "=";
```

8/3
```
      function "=" (Left, Right : Holder) return Boolean;
```

8.1/5
```
   {AI12-0112-1}    function Tampering_With_The_Element_Prohibited
        (Container : Holder) return Boolean
         with Nonblocking, Global => null, Use_Formal => null;
```

8.2/5
```
   {AI12-0339-1}    function Empty return Holder
         is (Empty_Holder)
         with Post =>
               not Tampering_With_The_Element_Prohibited (Empty'Result)
               and then Is_Empty (Empty'Result);
```

9/5
```
   {AI12-0112-1}    function To_Holder (New_Item : Element_Type) return Holder
         with Post => not Is_Empty (To_Holder'Result);
```

10/5
```
   {AI12-0112-1}    function Is_Empty (Container : Holder) return Boolean
         with Global => null, Use_Formal => null;
```

11/5
```
   {AI12-0112-1}    procedure Clear (Container : in out Holder)
         with Pre  => not Tampering_With_The_Element_Prohibited (Container)
                      or else raise Program_Error,
              Post => Is_Empty (Container);
```

12/5
```
   {AI12-0112-1}    function Element (Container : Holder) return Element_Type
         with Pre => not Is_Empty (Container) or else raise Constraint_Error,
              Global => null, Use_Formal => Element_Type;
```

13/5
```
   {AI12-0112-1}    procedure Replace_Element (Container : in out Holder;
                                               New_Item  : in     Element_Type)
         with Pre  => not Tampering_With_The_Element_Prohibited (Container)
                      or else raise Program_Error,
              Post => not Is_Empty (Container);
```

```
{AI12-0112-1}    procedure Query_Element                                                    14/5
     (Container : in Holder;
      Process   : not null access procedure (Element : in Element_Type))
      with Pre => not Is_Empty (Container) or else raise Constraint_Error;

{AI05-0069-1} {AI05-0248-1} {AI12-0112-1}    procedure Update_Element                    15/5
     (Container : in out Holder;
      Process   : not null access procedure (Element : in out Element_Type))
      with Pre => not Is_Empty (Container) or else raise Constraint_Error;

                   Is_Empty (Right) = Is_Empty (Left)'Old;

private                                                                                   23/3

   ... -- not specified by the language                                                   24/3

end Ada.Containers.Indefinite_Holders;                                                    25/3
```

{*AI05-0069-1*} The actual function for the generic formal function "=" on Element_Type values is expected to define a reflexive and symmetric relationship and return the same result value each time it is called with a particular pair of values. If it behaves in some other manner, the function "=" on holder values returns an unspecified value. The exact arguments and number of calls of this generic formal function by the function "=" on holder values are unspecified. 26/3

26.a/3 **Ramification:** If the actual function for "=" is not symmetric and consistent, the result returned by any of the functions defined to use "=" cannot be predicted. The implementation is not required to protect against "=" raising an exception, or returning random results, or any other "bad" behavior. And it can call "=" in whatever manner makes sense. But note that only the results of the function "=" is unspecified; other subprograms are not allowed to break if "=" is bad.

27/3 {*AI05-0069-1*} The type Holder is used to represent holder containers. The type Holder needs finalization (see 7.6).

28/3 {*AI05-0069-1*} Empty_Holder represents an empty holder object. If an object of type Holder is not otherwise initialized, it is initialized to the same value as Empty_Holder.

29/5 {*AI05-0069-1*} {*AI05-0262-1*} {*AI12-0112-1*} [Some operations check for “tampering with the element” of a container because they depend on the element of the container not being replaced.] When tampering with the element is *prohibited* for a particular holder object *H*, Program_Error is propagated by the finalization of *H*[, as well as by a call that passes *H* to certain of the operations of this package, as indicated by the precondition of such an operation].

Paragraphs 30 through 35 are removed as preconditions now describe these rules.

34.a/3 **Reason:** Complete replacement of an element can cause its memory to be deallocated while another operation is holding onto a reference to it. That can't be allowed. However, a simple modification of (part of) an element is not a problem, so Update_Element does not cause a problem.

36/3
```
function "=" (Left, Right : Holder) return Boolean;
```

37/3 {*AI05-0069-1*} If Left and Right denote the same holder object, then the function returns True. Otherwise, it compares the element contained in Left to the element contained in Right using the generic formal equality operator, returning the result of that operation. Any exception raised during the evaluation of element equality is propagated.

37.a/3 **Implementation Note:** This wording describes the canonical semantics. However, the order and number of calls on the formal equality **function** is unspecified, so an implementation need not call the equality function if the correct answer can be determined without doing so.

37.1/5
```
{AI12-0112-1} function Tampering_With_The_Element_Prohibited
  (Container : Holder) return Boolean
   with Nonblocking, Global => null, Use_Formal => null;
```

37.2/5 {*AI12-0112-1*} Returns True if tampering with the element is currently prohibited for Container, and returns False otherwise.

38/5
```
{AI12-0112-1} function To_Holder (New_Item : Element_Type) return Holder
   with Post => not Is_Empty (To_Holder'Result);
```

39/4 {*AI05-0069-1*} {*AI12-0035-1*} Returns a nonempty holder containing an element initialized to New_Item. To_Holder performs indefinite insertion (see A.18).

40/5
```
{AI12-0112-1} function Is_Empty (Container : Holder) return Boolean
   with Global => null, Use_Formal => null;
```

41/3 {*AI05-0069-1*} Returns True if Container is empty, and False if it contains an element.

42/5
```
{AI12-0112-1} procedure Clear (Container : in out Holder)
   with Pre  => not Tampering_With_The_Element_Prohibited (Container)
                or else raise Program_Error,
        Post => Is_Empty (Container);
```

43/5 {*AI05-0069-1*} {*AI12-0112-1*} Removes the element from Container.

44/5
```
{AI12-0112-1} function Element (Container : Holder) return Element_Type
   with Pre => not Is_Empty (Container) or else raise Constraint_Error,
        Global => null, Use_Formal => Element_Type;
```

45/5 {*AI05-0069-1*} {*AI12-0112-1*} Returns the element stored in Container.

```
{AI12-0112-1} procedure Replace_Element (Container : in out Holder;                    46/5
                                         New_Item  : in     Element_Type)
   with Pre  => not Tampering_With_The_Element_Prohibited (Container)
                 or else raise Program_Error,
        Post => not Is_Empty (Container);
```

{*AI05-0069-1*} {*AI12-0035-1*} {*AI12-0112-1*} Replace_Element assigns the value New_Item into Container, replacing any preexisting content of Container; Replace_Element performs indefinite insertion (see A.18). 47/5

```
{AI12-0112-1} procedure Query_Element                                                  48/5
  (Container : in Holder;
   Process   : not null access procedure (Element : in Element_Type))
   with Pre => not Is_Empty (Container) or else raise Constraint_Error,
        Global => null, Use_Formal => null;
```

{*AI05-0069-1*} {*AI05-0262-1*} {*AI05-0265-1*} {*AI12-0112-1*} Query_Element calls Process.**all** with the contained element as the argument. Tampering with the element of Container is prohibited during the execution of the call on Process.**all**. Any exception raised by Process.**all** is propagated. 49/5

Implementation Note: {*AI05-0005-1*} The "tamper with the element" check is intended to prevent the Element parameter of Process from being replaced or deleted outside of Process. The check prevents data loss (if Element_Type is passed by copy) or erroneous execution (if Element_Type is an unconstrained type). 49.a/3

```
{AI05-0069-1} {AI05-0248-1} {AI12-0112-1} procedure Update_Element                     50/5
  (Container : in out Holder;
   Process   : not null access procedure (Element : in out Element_Type))
   with Pre => not Is_Empty (Container) or else raise Constraint_Error;
```

{*AI05-0069-1*} {*AI05-0262-1*} {*AI05-0265-1*} {*AI12-0112-1*} Update_Element calls Process.**all** with the contained element as the argument. Tampering with the element of Container is prohibited during the execution of the call on Process.**all**. Any exception raised by Process.**all** is propagated. 51/5

Implementation Note: The Element parameter of Process.**all** may be constrained even if Element_Type is unconstrained. 51.a/3

```
{AI05-0212-1} {AI12-0112-1} type Constant_Reference_Type                               52/5
      (Element : not null access constant Element_Type) is private
   with Implicit_Dereference => Element,
        Nonblocking, Global => in out synchronized,
        Default_Initial_Condition => (raise Program_Error);

{AI05-0212-1} {AI12-0112-1} type Reference_Type (Element : not null access             53/5
Element_Type) is private
   with Implicit_Dereference => Element,
        Nonblocking, Global => in out synchronized,
        Default_Initial_Condition => (raise Program_Error);
```

{*AI05-0212-1*} The types Constant_Reference_Type and Reference_Type need finalization. 54/3

This paragraph was deleted.{*AI05-0212-1*} {*AI12-0112-1*} 55/5

Reason: It is expected that Reference_Type (and Constant_Reference_Type) will be a controlled type, for which finalization will have some action to terminate the tampering check for the associated container. If the object is created by default, however, there is no associated container. Since this is useless, and supporting this case would take extra work, we define it to raise an exception. 55.a/3

56/5
```
{AI05-0212-1} {AI12-0112-1} function Constant_Reference (Container : aliased in
Holder)
   return Constant_Reference_Type
   with Pre  => not Is_Empty (Container) or else raise Constraint_Error,
        Post => Tampering_With_The_Element_Prohibited (Container),
        Nonblocking, Global => null, Use_Formal => null;
```

57/3 {*AI05-0212-1*} This function (combined with the Implicit_Dereference aspect) provides a convenient way to gain read access to the contained element of a holder container.

58/5 {*AI05-0212-1*} {*AI05-0262-1*} {*AI05-0265-1*} {*AI12-0112-1*} Constant_Reference returns an object whose discriminant is an access value that designates the contained element. Tampering with the element of Container is prohibited while the object returned by Constant_Reference exists and has not been finalized.

59/5
```
{AI05-0212-1} {AI12-0112-1} function Reference (Container : aliased in out Holder)
   return Reference_Type
   with Pre  => not Is_Empty (Container) or else raise Constraint_Error,
        Post => Tampering_With_The_Element_Prohibited (Container),
        Nonblocking, Global => null, Use_Formal => null;
```

60/3 {*AI05-0212-1*} This function (combined with the Implicit_Dereference aspects) provides a convenient way to gain read and write access to the contained element of a holder container.

61/5 {*AI05-0212-1*} {*AI05-0262-1*} {*AI05-0265-1*} {*AI12-0112-1*} Reference returns an object whose discriminant is an access value that designates the contained element. Tampering with the element of Container is prohibited while the object returned by Reference exists and has not been finalized.

62/5
```
{AI12-0112-1} procedure Assign (Target : in out Holder; Source : in Holder)
   with Post => (Is_Empty (Source) = Is_Empty (Target));
```

63/3 {*AI05-0001-1*} If Target denotes the same object as Source, the operation has no effect. If Source is empty, Clear (Target) is called. Otherwise, Replace_Element (Target, Element (Source)) is called.

63.a/3 **Discussion:** {*AI05-0005-1*} This routine exists for compatibility with the other containers. For a holder, `Assign(A, B)` and `A := B` behave effectively the same. (Assign Clears the Target, while := finalizes the Target, but these should have similar effects.)

64/5
```
{AI12-0112-1} function Copy (Source : Holder) return Holder
   with Post => (Is_Empty (Source) = Is_Empty (Copy'Result));
```

65/3 {*AI05-0001-1*} If Source is empty, returns an empty holder container; otherwise, returns To_Holder (Element (Source)).

66/5
```
{AI12-0112-1} procedure Move (Target : in out Holder; Source : in out Holder)
   with Pre  => (not Tampering_With_The_Element_Prohibited (Target)
                    or else raise Program_Error) and then
                (not Tampering_With_The_Element_Prohibited (Source)
                    or else raise Program_Error),
        Post => (if not Target'Has_Same_Storage (Source) then
                    Is_Empty (Source) and then (not Is_Empty (Target)));
```

67/5 {*AI05-0069-1*} {*AI05-0248-1*} {*AI12-0112-1*} If Target denotes the same object as Source, then the operation has no effect. Otherwise, the element contained by Source (if any) is removed from Source and inserted into Target, replacing any preexisting content.

```
procedure Swap (Left, Right : in out Holder)
   with Pre  => (not Tampering_With_The_Element_Prohibited (Left)
                    or else raise Program_Error) and then
                (not Tampering_With_The_Element_Prohibited (Right)
                    or else raise Program_Error),
        Post => Is_Empty (Left) = Is_Empty (Right)'Old and then
                Is_Empty (Right) = Is_Empty (Left)'Old;
```

67.1/5

{*AI12-0350-1*} If Left denotes the same object as Right, then the operation has no effect. Otherwise, operation exchanges the elements (if any) contained by Left and Right. 67.2/5

Bounded (Run-Time) Errors

{*AI05-0022-1*} {*AI05-0069-1*} {*AI05-0248-1*} {*AI05-0262-1*} It is a bounded error for the actual function associated with a generic formal subprogram, when called as part of an operation of this package, to tamper with the element of any Holder parameter of the operation. Either Program_Error is raised, or the operation works as defined on the value of the Holder either prior to, or subsequent to, some or all of the modifications to the Holder. 68/3

{*AI05-0027-1*} {*AI05-0069-1*} It is a bounded error to call any subprogram declared in the visible part of Containers.Indefinite_Holders when the associated container has been finalized. If the operation takes Container as an **in out** parameter, then it raises Constraint_Error or Program_Error. Otherwise, the operation either proceeds as it would for an empty container, or it raises Constraint_Error or Program_Error. 69/3

Erroneous Execution

{*AI05-0212-1*} {*AI05-0269-1*} Execution is erroneous if the holder container associated with the result of a call to Reference or Constant_Reference is finalized before the result object returned by the call to Reference or Constant_Reference is finalized. 70/3

Reason: {*AI05-0212-1*} Each object of Reference_Type and Constant_Reference_Type probably contains some reference to the originating container. If that container is prematurely finalized (which is only possible via Unchecked_Deallocation, as accessibility checks prevent passing a container to Reference that will not live as long as the result), the finalization of the object of Reference_Type will try to access a nonexistent object. This is a normal case of a dangling pointer created by Unchecked_Deallocation; we have to explicitly mention it here as the pointer in question is not visible in the specification of the type. (This is the same reason we have to say this for invalid cursors.) 70.a/3

Implementation Requirements

{*AI05-0069-1*} No storage associated with a holder object shall be lost upon assignment or scope exit. 71/3

{*AI05-0069-1*} {*AI05-0269-1*} The execution of an assignment_statement for a holder container shall have the effect of copying the element (if any) from the source holder object to the target holder object. 72/3

Implementation Note: {*AI05-0298-1*} An assignment of a holder container is a "deep" copy; that is the element is copied as well as any data structures. We say "effect of" in order to allow the implementation to avoid copying the element immediately if it wishes. For instance, an implementation that avoided copying until one of the containers is modified would be allowed. (Note that this implementation would require care, see A.18.2 for more.) 72.a/3

Implementation Advice

{*AI05-0069-1*} {*AI05-0269-1*} {*AI12-0350-1*} Move and Swap should not copy any elements, and should minimize copying of internal data structures. 73/5

Implementation Advice: Move and Swap in Containers.Indefinite_Holders should not copy any elements, and should minimize copying of internal data structures. 73.a.1/5

Implementation Note: {*AI12-0350-1*} Usually that can be accomplished simply by moving the pointer(s) to the internal data structures appropriately. 73.a/5

{*AI05-0069-1*} {*AI05-0269-1*} If an exception is propagated from a holder operation, no storage should be lost, nor should the element be removed from a holder container unless specified by the operation. 74/3

74.a.1/3 **Implementation Advice:** If an exception is propagated from a holder operation, no storage should be lost, nor should the element be removed from a holder container unless specified by the operation.

74.a/3 **Reason:** This is important so that programs can recover from errors. But we don't want to require heroic efforts, so we just require documentation of cases where this can't be accomplished.

Extensions to Ada 2005

74.b/3 {*AI05-0069-1*} {*AI05-0084-1*} {*AI05-0265-1*} The generic package Containers.Indefinite_Holders is new.

Inconsistencies With Ada 2012

74.c/4 {*AI12-0035-1*} **Corrigendum:** Defined some routines to "perform indefinite insertion". This could mean that some calls to those routines would now raise Program_Error where they previously worked. However, this is extremely unlikely; see Inconsistencies With Ada 2012 in A.18.11 for details.

Incompatibilities With Ada 2012

74.d/5 {*AI12-0111-1*} {*AI12-0112-1*} {*AI12-0350-1*} A number of new subprograms and types were added to Containers.Indefinite_Holders to better support contracts and provide additional functionality. Therefore, a use clause conflict is possible; see the introduction of Annex A for more on this topic.

Wording Changes from Ada 2012

74.e/4 {*AI12-0110-1*} **Corrigendum:** Clarified that tampering checks precede all other checks made by a subprogram (but come after those associated with the call).

74.f/5 {*AI12-0112-1*} Added contracts to this container. This includes describing some of the semantics with pre- and postconditions, rather than English text. Note that the preconditions can be Suppressed (see 11.5).

A.18.19 The Generic Package Containers.Bounded_Vectors

1/3 {*AI05-0001-1*} The language-defined generic package Containers.Bounded_Vectors provides a private type Vector and a set of operations. It provides the same operations as the package Containers.Vectors (see A.18.2), with the difference that the maximum storage is bounded.

Static Semantics

2/3 {*AI05-0001-1*} The declaration of the generic library package Containers.Bounded_Vectors has the same contents and semantics as Containers.Vectors except:

3/5 - {*AI12-0112-1*} The aspect Preelaborate is replaced with aspect Pure. Aspect Global is deleted.

3.a/5 **Ramification:** {*AI12-0112-1*} The Global aspect for a Pure package is **null** (see 6.1.2), so we don't need to give it explicitly.

4/3 - The type Vector is declared with a discriminant that specifies the capacity:

5/5 {*AI12-0112-1*}
```
type Vector (Capacity : Count_Type) is tagged private...
```

5.1/5 - {*AI12-0409-1*} The aspect_definition for Preelaborable_Initialization for type Vector is changed to:

5.2/5
```
Preelaborable_Initialization =>
   Element_Type'Preelaborable_Initialization
```

6/3 - The type Vector needs finalization if and only if type Element_Type needs finalization.

6.a/3 **Implementation Note:** {*AI05-0212-1*} The type Vector cannot depend on package Ada.Finalization unless the element type depends on that package. The objects returned from the Iterator and Reference functions probably do depend on package Ada.Finalization. Restricted environments may need to avoid use of those functions and their associated types.

6.1/5 - {*AI12-0112-1*} Capacity is omitted from the Stable_Properties of type Vector.

6.b/5 **Reason:** The capacity is a discriminant here, so it can't be changed by most routines; thus including it in the stable properties adds no information.

6.2/5 - {*AI12-0339-1*} In function Empty, the postcondition is altered to:

```
Post =>
   Empty'Result.Capacity = Capacity and then
   not Tampering_With_Elements_Prohibited (Empty'Result) and then
   not Tampering_With_Cursors_Prohibited (Empty'Result) and then
   Length (Empty'Result) = 0;
```

6.3/5

- {*AI12-0112-1*} In function Copy, the postcondition is altered to: 7/5

```
Post => Length (Copy'Result) = Length (Source) and then
        (if Capacity > Length (Source) then
           Copy'Result.Capacity = Capacity
         else Copy'Result.Capacity >= Length (Source));
```

7.1/5

- The description of Reserve_Capacity is replaced with: 8/3

```
{AI12-0112-1}    procedure Reserve_Capacity (Container : in out Vector;
                                             Capacity  : in     Count_Type)
   with Pre => Capacity <= Container.Capacity
                  or else raise Capacity_Error;
```

8.1/5

{*AI12-0112-1*} This operation has no effect, [other than checking the precondition]. 9/5

- {*AI12-0112-1*} The portion of the postcondition checking the capacity is omitted from subprograms Set_Length, Assign, Insert, Insert_Space, Prepend, Append, and Delete. 9.1/5

- {*AI12-0112-1*} For procedures Insert, Insert_Space, Prepend, and Append, the part of the precondition reading: 9.2/5

```
(<some length> <= Maximum_Length - <some other length>
   or else raise Constraint_Error)
```

9.3/5

is replaced by: 9.4/5

```
(<some length> <= Maximum_Length - <some other length>
   or else raise Constraint_Error) and then
(<some length> <= Container.Capacity - <some other length>
   or else raise Capacity_Error)
```

9.5/5

Bounded (Run-Time) Errors

{*AI05-0160-1*} {*AI05-0265-1*} It is a bounded error to assign from a bounded vector object while tampering with elements [or cursors] of that object is prohibited. Either Program_Error is raised by the assignment, execution proceeds with the target object prohibiting tampering with elements [or cursors], or execution proceeds normally. 10/3

Proof: Tampering with elements includes tampering with cursors, so we only really need to talk about tampering with elements here; we mention cursors for clarity. 10.a/3

Erroneous Execution

{*AI05-0265-1*} When a bounded vector object *V* is finalized, if tampering with cursors is prohibited for *V* other than due to an assignment from another vector, then execution is erroneous. 11/3

Reason: This is a tampering event, but since the implementation is not allowed to use Ada.Finalization, it is not possible in a pure Ada implementation to detect this error. (There is no Finalize routine that will be called that could make the check.) Since the check probably cannot be made, the bad effects that could occur (such as an iterator going into an infinite loop or accessing a nonexistent element) cannot be prevented and we have to allow anything. We do allow re-assigning an object that only prohibits tampering because it was copied from another object as that cannot cause any negative effects. 11.a/3

Implementation Requirements

{*AI05-0184-1*} {*AI05-0264-1*} For each instance of Containers.Vectors and each instance of Containers.Bounded_Vectors, if the two instances meet the following conditions, then the output generated by the Vector'Output or Vector'Write subprograms of either instance shall be readable by the Vector'Input or Vector'Read of the other instance, respectively: 12/3

13/3 • {*AI05-0184-1*} {*AI05-0248-1*} the Element_Type parameters of the two instances are statically matching subtypes of the same type; and

14/3 • {*AI05-0184-1*} the output generated by Element_Type'Output or Element_Type'Write is readable by Element_Type'Input or Element_Type'Read, respectively (where Element_Type denotes the type of the two actual Element_Type parameters); and

15/3 • {*AI05-0184-1*} the preceding two conditions also hold for the Index_Type parameters of the instances.

Implementation Advice

16/3 {*AI05-0001-1*} Bounded vector objects should be implemented without implicit pointers or dynamic allocation.

16.a.1/3 **Implementation Advice:** Bounded vector objects should be implemented without implicit pointers or dynamic allocation.

17/3 {*AI05-0001-1*} The implementation advice for procedure Move to minimize copying does not apply.

17.a.1/3 **Implementation Advice:** The implementation advice for procedure Move to minimize copying does not apply to bounded vectors.

Extensions to Ada 2005

17.a/3 {*AI05-0001-1*} {*AI05-0160-1*} {*AI05-0184-1*} The generic package Containers.Bounded_Vectors is new.

Inconsistencies With Ada 2012

17.b/5 {*AI12-0111-1*} **Correction:** Tampering with elements is now defined to be equivalent to tampering with cursors for bounded containers. If a program requires tampering detection to work, it might fail in Ada 2022. Needless to say, this shouldn't happen outside of test programs. See Inconsistencies With Ada 2012 in A.18.2 for more details.

Incompatibilities With Ada 2012

17.c/5 {*AI12-0409-1*} **Correction:**A bounded vector now only has Preelaborable_Initialization (abbreviated PI in this note) when the actual for the Element_Type has PI. If an program used a vector whose actual Element_Type does not have PI in a context when PI is required (such as a library-level object in a preelaborated unit or as a component of a type with PI), the program would be illegal in Ada 2022 but legal in original Ada 2012. This situation is unlikely, especially as some existing Ada 2012 implementations reject the instance in this case.

A.18.20 The Generic Package Containers.Bounded_Doubly_Linked_Lists

1/3 {*AI05-0001-1*} The language-defined generic package Containers.Bounded_Doubly_Linked_Lists provides a private type List and a set of operations. It provides the same operations as the package Containers.Doubly_Linked_Lists (see A.18.3), with the difference that the maximum storage is bounded.

Static Semantics

2/3 {*AI05-0001-1*} The declaration of the generic library package Containers.Bounded_Doubly_Linked_Lists has the same contents and semantics as Containers.Doubly_Linked_Lists except:

3/5 • {*AI12-0112-1*} The aspect Preelaborate is replaced with aspect Pure. Aspect Global is deleted.

3.a/5 **Ramification:** {*AI12-0112-1*} The Global aspect for a Pure package is **null** (see 6.1.2), so we don't need to give it explicitly.

4/3 • The type List is declared with a discriminant that specifies the capacity (maximum number of elements) as follows:

5/5 {*AI12-0112-1*} `type List (Capacity : Count_Type) is tagged private...`

5.1/5 • {*AI12-0409-1*} The aspect_definition for Preelaborable_Initialization for type List is changed to:

```
Preelaborable_Initialization =>
   Element_Type'Preelaborable_Initialization
```
5.2/5

- The type List needs finalization if and only if type Element_Type needs finalization. 6/3

  Implementation Note: {*AI05-0212-1*} The type List cannot depend on package Ada.Finalization unless the element type depends on that package. The objects returned from the Iterator and Reference functions probably do depend on package Ada.Finalization. Restricted environments may need to avoid use of those functions and their associated types. 6.a/3

- {*AI12-0339-1*} The function Empty is replaced by: 6.1/5

```
function Empty (Capacity : Count_Type := implementation-defined)
   return List
   with Post =>
         Empty'Result.Capacity = Capacity and then
         not Tampering_With_Elements_Prohibited (Empty'Result) and then
         not Tampering_With_Cursors_Prohibited (Empty'Result) and then
         Length (Empty'Result) = 0;
```
6.2/5

- {*AI12-0112-1*} For procedures Insert, Prepend, Append, Merge, and the three-parameter Splice whose parameter Source has type List, the part of the precondition reading: 7/5

```
(<some length> <= Count_Type'Last - <some other length>
   or else raise Constraint_Error)
```
7.1/5

  is replaced by: 7.2/5

```
(<some length> <= Count_Type'Last - <some other length>
   or else raise Constraint_Error) and then
(<some length> <= Container.Capacity - <some other length>
   or else raise Capacity_Error)
```
7.3/5

- {*AI12-0112-1*} In procedure Assign, the precondition is altered to: 8/5

```
Pre => (not Tampering_With_Cursors_Prohibited (Target)
          or else raise Program_Error) and then
       (Length (Source) <= Target.Capacity
          or else raise Capacity_Error),
```
8.1/5

- The function Copy is replaced with: 9/3

{*AI12-0112-1*}
```
function Copy (Source : List; Capacity : Count_Type := 0)
   return List
   with Pre  => Capacity = 0 or else Capacity >= Length (Source)
                   or else raise Capacity_Error,
        Post =>
           Length (Copy'Result) = Length (Source) and then
           not Tampering_With_Elements_Prohibited (Copy'Result) and then
           not Tampering_With_Cursors_Prohibited (Copy'Result) and then
           Copy'Result.Capacity = (if Capacity = 0 then
              Length (Source) else Capacity);
```
10/5

  Returns a list whose elements have the same values as the elements of Source. 11/5

- *This paragraph was deleted.*{*AI12-0112-1*} 12/5

- {*AI12-0112-1*} In the four-parameter procedure Splice, the precondition is altered to: 13/5

13.1/5
```
Pre  => (not Tampering_With_Cursors_Prohibited (Target)
            or else raise Program_Error) and then
         (not Tampering_With_Cursors_Prohibited (Source)
            or else raise Program_Error) and then
         (Position /= No_Element
            or else raise Constraint_Error) and then
         (Has_Element (Source, Position)
            or else raise Program_Error) and then
         (Before = No_Element or else Has_Element (Target, Before)
            or else raise Program_Error) and then
         (Target'Has_Same_Storage (Source) or else
          Length (Target) /= Count_Type'Last
            or else raise Constraint_Error) and then
         (Target'Has_Same_Storage (Source) or else
          Length (Target) /= Target.Capacity
            or else raise Capacity_Error),
```

Bounded (Run-Time) Errors

14/3 {*AI05-0160-1*} {*AI05-0265-1*} It is a bounded error to assign from a bounded list object while tampering with elements [or cursors] of that object is prohibited. Either Program_Error is raised by the assignment, execution proceeds with the target object prohibiting tampering with elements [or cursors], or execution proceeds normally.

14.a/3 **Proof:** Tampering with elements includes tampering with cursors, so we only really need to talk about tampering with elements here; we mention cursors for clarity.

Erroneous Execution

15/3 {*AI05-0265-1*} When a bounded list object *L* is finalized, if tampering with cursors is prohibited for *L* other than due to an assignment from another list, then execution is erroneous.

15.a/3 **Reason:** This is a tampering event, but since the implementation is not allowed to use Ada.Finalization, it is not possible in a pure Ada implementation to detect this error. (There is no Finalize routine that will be called that could make the check.) Since the check probably cannot be made, the bad effects that could occur (such as an iterator going into an infinite loop or accessing a nonexistent element) cannot be prevented and we have to allow anything. We do allow re-assigning an object that only prohibits tampering because it was copied from another object as that cannot cause any negative effects.

Implementation Requirements

16/3 {*AI05-0184-1*} {*AI05-0264-1*} For each instance of Containers.Doubly_Linked_Lists and each instance of Containers.Bounded_Doubly_Linked_Lists, if the two instances meet the following conditions, then the output generated by the List'Output or List'Write subprograms of either instance shall be readable by the List'Input or List'Read of the other instance, respectively:

17/3 - {*AI05-0184-1*} {*AI05-0248-1*} the Element_Type parameters of the two instances are statically matching subtypes of the same type; and

18/3 - {*AI05-0184-1*} the output generated by Element_Type'Output or Element_Type'Write is readable by Element_Type'Input or Element_Type'Read, respectively (where Element_Type denotes the type of the two actual Element_Type parameters).

Implementation Advice

19/3 {*AI05-0001-1*} Bounded list objects should be implemented without implicit pointers or dynamic allocation.

19.a.1/3 **Implementation Advice:** Bounded list objects should be implemented without implicit pointers or dynamic allocation.

20/3 {*AI05-0001-1*} The implementation advice for procedure Move to minimize copying does not apply.

20.a.1/3 **Implementation Advice:** The implementation advice for procedure Move to minimize copying does not apply to bounded lists.

Extensions to Ada 2005

{*AI05-0001-1*} {*AI05-0160-1*} {*AI05-0184-1*} The generic package Containers.Bounded_Doubly_Linked_Lists is new. 20.a/3

Inconsistencies With Ada 2012

{*AI12-0111-1*} **Correction:** Tampering with elements is now defined to be equivalent to tampering with cursors for bounded containers. If a program requires tampering detection to work, it might fail in Ada 2022. Needless to say, this shouldn't happen outside of test programs. See Inconsistencies With Ada 2012 in A.18.2 for more details. 20.b/5

Incompatibilities With Ada 2012

{*AI12-0409-1*} **Correction:**A bounded list now only has Preelaborable_Initialization (abbreviated PI in this note) when the actual for the Element_Type has PI. If an program used a list whose actual Element_Type does not have PI in a context when PI is required (such as a library-level object in a preelaborated unit or as a component of a type with PI), the program would be illegal in Ada 2022 but legal in original Ada 2012. This situation is unlikely, especially as some existing Ada 2012 implementations reject the instance in this case. 20.c/5

A.18.21 The Generic Package Containers.Bounded_Hashed_Maps

{*AI05-0001-1*} The language-defined generic package Containers.Bounded_Hashed_Maps provides a private type Map and a set of operations. It provides the same operations as the package Containers.Hashed_Maps (see A.18.5), with the difference that the maximum storage is bounded. 1/3

Static Semantics

{*AI05-0001-1*} The declaration of the generic library package Containers.Bounded_Hashed_Maps has the same contents and semantics as Containers.Hashed_Maps except: 2/3

- {*AI12-0112-1*} The aspect Preelaborate is replaced with aspect Pure. Aspect Global is deleted. 3/5
- The type Map is declared with discriminants that specify both the capacity (number of elements) and modulus (number of distinct hash values) of the hash table as follows: 4/3

```
{AI12-0112-1}   type Map (Capacity : Count_Type;                    5/5
                Modulus  : Hash_Type) is tagged private...
```

- {*AI12-0409-1*} The aspect_definition for Preelaborable_Initialization for type Map is changed to: 5.1/5

```
Preelaborable_Initialization =>                                     5.2/5
   Element_Type'Preelaborable_Initialization
      and
   Key_Type'Preelaborable_Initialization
```

- The type Map needs finalization if and only if type Key_Type or type Element_Type needs finalization. 6/3

  Implementation Note: {*AI05-0212-1*} The type Map cannot depend on package Ada.Finalization unless the element or key type depends on that package. The objects returned from the Iterator and Reference functions probably do depend on package Ada.Finalization. Restricted environments may need to avoid use of those functions and their associated types. 6.a/3

- {*AI12-0339-1*} In function Empty, the postcondition is altered to: 6.1/5

```
Post =>                                                             6.2/5
   Empty'Result.Capacity = Capacity and then
   Empty'Result.Modulus = Default_Modulus (Capacity) and then
   not Tampering_With_Elements_Prohibited (Empty'Result) and then
   not Tampering_With_Cursors_Prohibited (Empty'Result) and then
   Length (Empty'Result) = 0;
```

- The description of Reserve_Capacity is replaced with: 7/3

```
{AI12-0112-1}    procedure Reserve_Capacity (Container : in out Map;  7.1/5
                                             Capacity  : in     Count_Type)
      with Pre => Capacity <= Container.Capacity
                      or else raise Capacity_Error;
```

8/5 {*AI12-0112-1*} This operation has no effect, [other than checking the precondition].

9/3 • An additional operation is added immediately following Reserve_Capacity:

10/3
```
function Default_Modulus (Capacity : Count_Type) return Hash_Type;
```

11/3 Default_Modulus returns an implementation-defined value for the number of distinct hash values to be used for the given capacity (maximum number of elements).

11.1/5 • {*AI12-0112-1*} For procedures Insert and Include, the part of the precondition reading:

11.2/5
```
(<some length> <= Count_Type'Last - <some other length>
   or else raise Constraint_Error)
```

11.3/5 is replaced by:

11.4/5
```
(<some length> <= Count_Type'Last - <some other length>
   or else raise Constraint_Error) and then
(<some length> > Container.Capacity - <some other length>
   or else raise Capacity_Error)
```

11.5/5 • {*AI12-0112-1*} In procedure Assign, the precondition is altered to:

11.6/5
```
Pre => (not Tampering_With_Cursors_Prohibited (Target)
          or else raise Program_Error) and then
       (Length (Source) <= Target.Capacity
          or else raise Capacity_Error),
```

12/3 • The function Copy is replaced with:

13/5
```
{AI12-0112-1}   function Copy (Source   : Map;
                               Capacity : Count_Type := 0;
                               Modulus  : Hash_Type := 0) return Map
     with Pre  => Capacity = 0 or else Capacity >= Length (Source)
                     or else raise Capacity_Error,
          Post =>
             Length (Copy'Result) = Length (Source) and then
             not Tampering_With_Elements_Prohibited (Copy'Result) and then
             not Tampering_With_Cursors_Prohibited (Copy'Result) and then
             Copy'Result.Capacity = (if Capacity = 0 then
                Length (Source) else Capacity) and then
             Copy'Result.Modulus = (if Modulus = 0 then
                Default_Modulus (Capacity) else Modulus);
```

14/5 {*AI05-0264-1*} Returns a map with key/element pairs initialized from the values in Source.

Bounded (Run-Time) Errors

15/3 {*AI05-0160-1*} {*AI05-0265-1*} It is a bounded error to assign from a bounded map object while tampering with elements [or cursors] of that object is prohibited. Either Program_Error is raised by the assignment, execution proceeds with the target object prohibiting tampering with elements [or cursors], or execution proceeds normally.

15.a/3 **Proof:** Tampering with elements includes tampering with cursors, so we only really need to talk about tampering with elements here; we mention cursors for clarity.

Erroneous Execution

16/3 {*AI05-0265-1*} When a bounded map object *M* is finalized, if tampering with cursors is prohibited for *M* other than due to an assignment from another map, then execution is erroneous.

16.a/3 **Reason:** This is a tampering event, but since the implementation is not allowed to use Ada.Finalization, it is not possible in a pure Ada implementation to detect this error. (There is no Finalize routine that will be called that could make the check.) Since the check probably cannot be made, the bad effects that could occur (such as an iterator going into an infinite loop or accessing a nonexistent element) cannot be prevented and we have to allow anything. We do allow re-assigning an object that only prohibits tampering because it was copied from another object as that cannot cause any negative effects.

Implementation Requirements

{*AI05-0184-1*} {*AI05-0264-1*} For each instance of Containers.Hashed_Maps and each instance of Containers.Bounded_Hashed_Maps, if the two instances meet the following conditions, then the output generated by the Map'Output or Map'Write subprograms of either instance shall be readable by the Map'Input or Map'Read of the other instance, respectively: 17/3

- {*AI05-0184-1*} {*AI05-0248-1*} the Element_Type parameters of the two instances are statically matching subtypes of the same type; and 18/3
- {*AI05-0184-1*} the output generated by Element_Type'Output or Element_Type'Write is readable by Element_Type'Input or Element_Type'Read, respectively (where Element_Type denotes the type of the two actual Element_Type parameters); and 19/3
- {*AI05-0184-1*} the preceding two conditions also hold for the Key_Type parameters of the instances. 20/3

Implementation Advice

{*AI05-0001-1*} {*AI05-0269-1*} Bounded hashed map objects should be implemented without implicit pointers or dynamic allocation. 21/3

Implementation Advice: Bounded hashed map objects should be implemented without implicit pointers or dynamic allocation. 21.a.1/3

{*AI05-0001-1*} The implementation advice for procedure Move to minimize copying does not apply. 22/3

Implementation Advice: The implementation advice for procedure Move to minimize copying does not apply to bounded hashed maps. 22.a.1/3

Extensions to Ada 2005

6.1/5 • {*AI12-0339-1*} The function Empty is replaced by:

6.2/5
```
function Empty (Capacity : Count_Type := implementation-defined)
   return Map
   with Post =>
         Empty'Result.Capacity = Capacity and then
         not Tampering_With_Elements_Prohibited (Empty'Result) and then
         not Tampering_With_Cursors_Prohibited (Empty'Result) and then
         Length (Empty'Result) = 0;
```

7/5 • {*AI12-0112-1*} For procedures Insert and Include, the part of the precondition reading:

7.1/5
```
(<some length> <= Count_Type'Last - <some other length>
   or else raise Constraint_Error)
```

7.2/5 is replaced by:

7.3/5
```
(<some length> <= Count_Type'Last - <some other length>
    or else raise Constraint_Error) and then
 (<some length> <= Container.Capacity - <some other length>
    or else raise Capacity_Error)
```

8/5 • {*AI12-0112-1*} In procedure Assign, the precondition is altered to:

8.1/5
```
Pre => (not Tampering_With_Cursors_Prohibited (Target)
          or else raise Program_Error) and then
       (Length (Source) <= Target.Capacity
          or else raise Capacity_Error),
```

9/3 • The function Copy is replaced with:

10/5
```
{AI12-0112-1}   function Copy (Source   : Map;
                  Capacity : Count_Type := 0) return Map
     with Pre  => Capacity = 0 or else Capacity >= Length (Source)
                     or else raise Capacity_Error,
          Post =>
             Length (Copy'Result) = Length (Source) and then
             not Tampering_With_Elements_Prohibited (Copy'Result) and then
             not Tampering_With_Cursors_Prohibited (Copy'Result) and then
             Copy'Result.Capacity = (if Capacity = 0 then
                Length (Source) else Capacity);
```

11/5 {*AI12-0112-1*} Returns a map with key/element pairs initialized from the values in Source.

Bounded (Run-Time) Errors

12/3 {*AI05-0160-1*} {*AI05-0265-1*} It is a bounded error to assign from a bounded map object while tampering with elements [or cursors] of that object is prohibited. Either Program_Error is raised by the assignment, execution proceeds with the target object prohibiting tampering with elements [or cursors], or execution proceeds normally.

12.a/3 **Proof:** Tampering with elements includes tampering with cursors, so we only really need to talk about tampering with elements here; we mention cursors for clarity.

Erroneous Execution

{*AI05-0265-1*} When a bounded map object *M* is finalized, if tampering with cursors is prohibited for *M* other than due to an assignment from another map, then execution is erroneous. 13/3

Reason: This is a tampering event, but since the implementation is not allowed to use Ada.Finalization, it is not possible in a pure Ada implementation to detect this error. (There is no Finalize routine that will be called that could make the check.) Since the check probably cannot be made, the bad effects that could occur (such as an iterator going into an infinite loop or accessing a nonexistent element) cannot be prevented and we have to allow anything. We do allow re-assigning an object that only prohibits tampering because it was copied from another object as that cannot cause any negative effects. 13.a/3

Implementation Requirements

{*AI05-0184-1*} {*AI05-0264-1*} For each instance of Containers.Ordered_Maps and each instance of Containers.Bounded_Ordered_Maps, if the two instances meet the following conditions, then the output generated by the Map'Output or Map'Write subprograms of either instance shall be readable by the Map'Input or Map'Read of the other instance, respectively: 14/3

- {*AI05-0184-1*} {*AI05-0248-1*} the Element_Type parameters of the two instances are statically matching subtypes of the same type; and 15/3
- {*AI05-0184-1*} the output generated by Element_Type'Output or Element_Type'Write is readable by Element_Type'Input or Element_Type'Read, respectively (where Element_Type denotes the type of the two actual Element_Type parameters); and 16/3
- {*AI05-0184-1*} the preceding two conditions also hold for the Key_Type parameters of the instances. 17/3

Implementation Advice

{*AI05-0001-1*} {*AI05-0269-1*} Bounded ordered map objects should be implemented without implicit pointers or dynamic allocation. 18/3

Implementation Advice: Bounded ordered map objects should be implemented without implicit pointers or dynamic allocation. 18.a.1/3

{*AI05-0001-1*} The implementation advice for procedure Move to minimize copying does not apply. 19/3

Implementation Advice: The implementation advice for procedure Move to minimize copying does not apply to bounded ordered maps. 19.a.1/3

Extensions to Ada 2005

{*AI05-0001-1*} {*AI05-0160-1*} {*AI05-0184-1*} The generic package Containers.Bounded_Ordered_Maps is new. 19.a/3

Inconsistencies With Ada 2012

{*AI12-0111-1*} **Correction:** Tampering with elements is now defined to be equivalent to tampering with cursors for bounded containers. If a program requires tampering detection to work, it might fail in Ada 2022. Needless to say, this shouldn't happen outside of test programs. See Inconsistencies With Ada 2012 in A.18.2 for more details. 19.b/5

Incompatibilities With Ada 2012

{*AI12-0409-1*} **Correction:**A bounded map now only has Preelaborable_Initialization (abbreviated PI in this note) when the actuals for the Element_Type and the Key_Type have PI. If an program used a map whose actual Element_Type or Key_Type does not have PI in a context when PI is required (such as a library-level object in a preelaborated unit or as a component of a type with PI), the program would be illegal in Ada 2022 but legal in original Ada 2012. This situation is unlikely, especially as some existing Ada 2012 implementations reject the instance in this case. 19.c/5

A.18.23 The Generic Package Containers.Bounded_Hashed_Sets

1/3 {*AI05-0001-1*} The language-defined generic package Containers.Bounded_Hashed_Sets provides a private type Set and a set of operations. It provides the same operations as the package Containers.Hashed_Sets (see A.18.8), with the difference that the maximum storage is bounded.

Static Semantics

2/3 {*AI05-0001-1*} The declaration of the generic library package Containers.Bounded_Hashed_Sets has the same contents and semantics as Containers.Hashed_Sets except:

3/5 - {*AI12-0112-1*} The aspect Preelaborate is replaced with aspect Pure. Aspect Global is deleted.

4/3 - The type Set is declared with discriminants that specify both the capacity (number of elements) and modulus (number of distinct hash values) of the hash table as follows:

5/5 ```
{AI12-0112-1}   type Set (Capacity : Count_Type;
                          Modulus : Hash_Type) is tagged private...
```

5.1/5 - {*AI12-0409-1*} The aspect_definition for Preelaborable_Initialization for type Set is changed to:

5.2/5 ```
Preelaborable_Initialization =>
   Element_Type'Preelaborable_Initialization
```

6/3 - The type Set needs finalization if and only if type Element_Type needs finalization.

6.a/3 **Implementation Note:** {*AI05-0212-1*} The type Set cannot depend on package Ada.Finalization unless the element or key type depends on that package. The objects returned from the Iterator and Reference functions probably do depend on package Ada.Finalization. Restricted environments may need to avoid use of those functions and their associated types.

6.1/5 - {*AI12-0339-1*} In function Empty, the postcondition is altered to:

6.2/5 ```
Post =>
   Empty'Result.Capacity = Capacity and then
   Empty'Result.Modulus = Default_Modulus (Capacity) and then
   not Tampering_With_Cursors_Prohibited (Empty'Result) and then
   Length (Empty'Result) = 0;
```

7/3 - The description of Reserve_Capacity is replaced with:

7.1/5 ```
{AI12-0112-1}    procedure Reserve_Capacity (Container : in out Set;
                                             Capacity  : in     Count_Type)
      with Pre => Capacity <= Container.Capacity
         or else raise Capacity_Error;
```

8/5 {*AI12-0112-1*} This operation has no effect, [other than checking the precondition].

9/3 - An additional operation is added immediately following Reserve_Capacity:

10/3 ```
function Default_Modulus (Capacity : Count_Type) return Hash_Type;
```

11/3 Default_Modulus returns an implementation-defined value for the number of distinct hash values to be used for the given capacity (maximum number of elements).

11.1/5 - {*AI12-0112-1*} For procedures Insert and Include, the part of the precondition reading:

11.2/5 ```
(<some length> <= Count_Type'Last - <some other length>
   or else raise Constraint_Error)
```

11.3/5 is replaced by:

11.4/5 ```
(<some length> <= Count_Type'Last - <some other length>
   or else raise Constraint_Error) and then
(<some length> <= Container.Capacity - <some other length>
   or else raise Capacity_Error)
```

11.5/5 - {*AI12-0112-1*} In procedure Assign, the precondition is altered to:
```

```
      Pre => (not Tampering_With_Cursors_Prohibited (Target)                    11.6/5
                 or else raise Program_Error) and then
              (Length (Source) <= Target.Capacity
                 or else raise Capacity_Error),
```

- The function Copy is replaced with: 12/3

```
{AI12-0112-1}   function Copy (Source   : Set;                                13/5
                               Capacity : Count_Type := 0;
                               Modulus  : Hash_Type := 0) return Map
     with Pre  => Capacity = 0 or else Capacity >= Length (Source)
                     or else raise Capacity_Error,
          Post =>
             Length (Copy'Result) = Length (Source) and then
             not Tampering_With_Cursors_Prohibited (Copy'Result) and then
             Copy'Result.Capacity = (if Capacity = 0 then
                Length (Source) else Capacity) and then
             Copy'Result.Modulus = (if Modulus = 0 then
                Default_Modulus (Capacity) else Modulus);
```

{*AI05-0264-1*} Returns a set with key/element pairs initialized from the values in Source. 14/5

Bounded (Run-Time) Errors

{*AI05-0160-1*} {*AI05-0265-1*} It is a bounded error to assign from a bounded set object while tampering with elements [or cursors] of that object is prohibited. Either Program_Error is raised by the assignment, execution proceeds with the target object prohibiting tampering with elements [or cursors], or execution proceeds normally. 15/3

Proof: Tampering with elements includes tampering with cursors, so we only really need to talk about tampering with elements here; we mention cursors for clarity. 15.a/3

Erroneous Execution

{*AI05-0265-1*} When a bounded set object *S* is finalized, if tampering with cursors is prohibited for *S* other than due to an assignment from another set, then execution is erroneous. 16/3

Reason: This is a tampering event, but since the implementation is not allowed to use Ada.Finalization, it is not possible in a pure Ada implementation to detect this error. (There is no Finalize routine that will be called that could make the check.) Since the check probably cannot be made, the bad effects that could occur (such as an iterator going into an infinite loop or accessing a nonexistent element) cannot be prevented and we have to allow anything. We do allow re-assigning an object that only prohibits tampering because it was copied from another object as that cannot cause any negative effects. 16.a/3

Implementation Requirements

{*AI05-0184-1*} {*AI05-0264-1*} For each instance of Containers.Hashed_Sets and each instance of Containers.Bounded_Hashed_Sets, if the two instances meet the following conditions, then the output generated by the Set'Output or Set'Write subprograms of either instance shall be readable by the Set'Input or Set'Read of the other instance, respectively: 17/3

- {*AI05-0184-1*} {*AI05-0248-1*} the Element_Type parameters of the two instances are statically matching subtypes of the same type; and 18/3
- {*AI05-0184-1*} the output generated by Element_Type'Output or Element_Type'Write is readable by Element_Type'Input or Element_Type'Read, respectively (where Element_Type denotes the type of the two actual Element_Type parameters). 19/3

Implementation Advice

{*AI05-0001-1*} {*AI05-0269-1*} Bounded hashed set objects should be implemented without implicit pointers or dynamic allocation. 20/3

Implementation Advice: Bounded hashed set objects should be implemented without implicit pointers or dynamic allocation. 20.a.1/3

21/3 {*AI05-0001-1*} The implementation advice for procedure Move to minimize copying does not apply.

21.a.1/3 **Implementation Advice:** The implementation advice for procedure Move to minimize copying does not apply to bounded hashed sets.

Extensions to Ada 2005

21.a/3 {*AI05-0001-1*} {*AI05-0160-1*} {*AI05-0184-1*} The generic package Containers.Bounded_Hashed_Sets is new.

Incompatibilities With Ada 2012

21.b/5 {*AI12-0409-1*} **Correction:**A bounded set now only has Preelaborable_Initialization (abbreviated PI in this note) when the actual for the Element_Type has PI. If an program used a set whose actual Element_Type does not have PI in a context when PI is required (such as a library-level object in a preelaborated unit or as a component of a type with PI), the program would be illegal in Ada 2022 but legal in original Ada 2012. This situation is unlikely, especially as some existing Ada 2012 implementations reject the instance in this case.

A.18.24 The Generic Package Containers.Bounded_Ordered_Sets

1/3 {*AI05-0001-1*} The language-defined generic package Containers.Bounded_Ordered_Sets provides a private type Set and a set of operations. It provides the same operations as the package Containers.Ordered_Sets (see A.18.9), with the difference that the maximum storage is bounded.

Static Semantics

2/3 {*AI05-0001-1*} The declaration of the generic library package Containers.Bounded_Ordered_Sets has the same contents and semantics as Containers.Ordered_Sets except:

3/5 - {*AI12-0112-1*} The aspect Preelaborate is replaced with aspect Pure. Aspect Global is deleted.

4/3 - The type Set is declared with a discriminant that specifies the capacity (maximum number of elements) as follows:

5/5 {*AI12-0112-1*}
```
type Set (Capacity : Count_Type) is tagged private...
```

5.1/5 - {*AI12-0409-1*} The aspect_definition for Preelaborable_Initialization for type Set is changed to:

5.2/5
```
Preelaborable_Initialization =>
   Element_Type'Preelaborable_Initialization
```

6/3 - The type Set needs finalization if and only if type Element_Type needs finalization.

6.a/3 **Implementation Note:** {*AI05-0212-1*} The type Set cannot depend on package Ada.Finalization unless the element type depends on that package. The objects returned from the Iterator and Reference functions probably do depend on package Ada.Finalization. Restricted environments may need to avoid use of those functions and their associated types.

6.1/5 - {*AI12-0339-1*} The function Empty is replaced by:

6.2/5
```
function Empty (Capacity : Count_Type := implementation-defined)
   return Set
   with Post =>
         Empty'Result.Capacity = Capacity and then
         not Tampering_With_Cursors_Prohibited (Empty'Result) and then
         Length (Empty'Result) = 0;
```

7/5 - {*AI12-0112-1*} For procedures Insert and Include, the part of the precondition reading:

7.1/5
```
(<some length> <= Count_Type'Last - <some other length>
   or else raise Constraint_Error)
```

7.2/5 is replaced by:

7.3/5
```
(<some length> <= Count_Type'Last - <some other length>
   or else raise Constraint_Error) and then
(<some length> <= Container.Capacity - <some other length>
   or else raise Capacity_Error)
```

8/5 - {*AI12-0112-1*} In procedure Assign, the precondition is altered to:

```
      Pre => (not Tampering_With_Cursors_Prohibited (Target)                    8.1/5
                or else raise Program_Error) and then
              (Length (Source) <= Target.Capacity
                or else raise Capacity_Error),
```

- The function Copy is replaced with: 9/3

```
{AI12-0112-1}   function Copy (Source   : Set;                                10/5
                  Capacity : Count_Type := 0) return Map
     with Pre  => Capacity = 0 or else Capacity >= Length (Source)
                     or else raise Capacity_Error,
          Post =>
             Length (Copy'Result) = Length (Source) and then
             not Tampering_With_Cursors_Prohibited (Copy'Result) and then
             Copy'Result.Capacity = (if Capacity = 0 then
                Length (Source) else Capacity);
```

{*AI12-0112-1*} Returns a set with key/element pairs initialized from the values in Source. 11/5

Bounded (Run-Time) Errors

{*AI05-0160-1*} {*AI05-0265-1*} It is a bounded error to assign from a bounded set object while tampering with elements [or cursors] of that object is prohibited. - {*AI05-0184-1*} the output generated by Element_Type'Output or Element_Type'Write is readable by Element_Type'Input or Element_Type'Read, respectively (where Element_Type denotes the type of the two actual Element_Type parameters). 16/3

Implementation Advice

{*AI05-0001-1*} {*AI05-0269-1*} Bounded ordered set objects should be implemented without implicit pointers or dynamic allocation. 17/3

Implementation Advice: Bounded ordered set objects should be implemented without implicit pointers or dynamic allocation. 17.a.1/3

{*AI05-0001-1*} The implementation advice for procedure Move to minimize copying does not apply. 18/3

18.a.1/3 **Implementation Advice:** The implementation advice for procedure Move to minimize copying does not apply to bounded ordered sets.

Extensions to Ada 2005

18.a/3 {*AI05-0001-1*} {*AI05-0160-1*} {*AI05-0184-1*} The generic package Containers.Bounded_Ordered_Sets is new.

Incompatibilities With Ada 2012

18.b/5 {*AI12-0409-1*} **Correction:**A bounded set now only has Preelaborable_Initialization (abbreviated PI in this note) when the actual for the Element_Type has PI. If an program used a set whose actual Element_Type does not have PI in a context when PI is required (such as a library-level object in a preelaborated unit or as a component of a type with PI), the program would be illegal in Ada 2022 but legal in original Ada 2012. This situation is unlikely, especially as some existing Ada 2012 implementations reject the instance in this case.

A.18.25 The Generic Package Containers.Bounded_Multiway_Trees

1/3 {*AI05-0136-1*} The language-defined generic package Containers.Bounded_Multiway_Trees provides a private type Tree and a set of operations. It provides the same operations as the package Containers.Multiway_Trees (see A.18.10), with the difference that the maximum storage is bounded.

Static Semantics

2/3 {*AI05-0136-1*} The declaration of the generic library package Containers.Bounded_Multiway_Trees has the same contents and semantics as Containers.Multiway_Trees except:

3/5 - {*AI12-0112-1*} The aspect Preelaborate is replaced with aspect Pure. Aspect Global is deleted.

4/3 - The type Tree is declared with a discriminant that specifies the capacity (maximum number of elements) as follows:

5/5 {*AI12-0112-1*}
```
type Tree (Capacity : Count_Type) is tagged private...
```

5.1/5 - {*AI12-0409-1*} The aspect_definition for Preelaborable_Initialization for type Tree is changed to:

5.2/5
```
Preelaborable_Initialization =>
   Element_Type'Preelaborable_Initialization
```

6/3 - The type Tree needs finalization if and only if type Element_Type needs finalization.

6.a/3 **Implementation Note:** {*AI05-0212-1*} The type Tree cannot depend on package Ada.Finalization unless the element type depends on that package. The objects returned from the Iterator and Reference functions probably do depend on package Ada.Finalization. Restricted environments may need to avoid use of those functions and their associated types.

6.1/5 - {*AI12-0339-1*} The function Empty is replaced by:

6.2/5
```
function Empty (Capacity : Count_Type := implementation-defined)
   return Tree
   with Post =>
         Empty'Result.Capacity = Capacity and then
         not Tampering_With_Elements_Prohibited (Empty'Result) and then
         not Tampering_With_Cursors_Prohibited (Empty'Result) and then
         Node_Count (Empty'Result) = 1;
```

7/5 - {*AI12-0112-1*} For procedures Insert_Child, Prepend_Child, and Append_Child, the initial subexpression of the precondition is replaced with:

7.1/5
```
with Pre => (not Tampering_With_Cursors_Prohibited (Container)
                or else raise Program_Error) and then
             (Node_Count (Container) - 1 <= Container.Capacity - Count
                or else raise Capacity_Error)
```

8/5 - {*AI12-0112-1*} In procedure Assign, the precondition is altered to:

8.1/5
```
Pre => (not Tampering_With_Cursors_Prohibited (Target)
           or else raise Program_Error) and then
        (Node_Count (Source) - 1 <= Target.Capacity
           or else raise Capacity_Error),
```

- Function Copy is declared as follows: 9/3

{*AI12-0056-1*} 10/4
```
function Copy (Source : Tree; Capacity : Count_Type := 0)
   return Tree
   with Pre  => Capacity = 0 or else Capacity >= Node_Count (Source) - 1
                   or else raise Capacity_Error,
        Post =>
           Node_Count (Copy'Result) = Node_Count (Source) and then
           not Tampering_With_Elements_Prohibited (Copy'Result) and then
           not Tampering_With_Cursors_Prohibited (Copy'Result) and then
           Copy'Result.Capacity = (if Capacity = 0 then
              Node_Count (Source) - 1 else Capacity);
```

Returns a list whose elements have the same values as the elements of Source. 11/5

- {*AI12-0112-1*} In the four-parameter procedure Copy_Subtree, the last **or else** of the precondition is replaced by: 11.1/5

```
(not Is_Root (Source)                                                    11.2/5
   or else raise Constraint_Error) and then
(Node_Count (Target) - 1 + Subtree_Node_Count (Source) <=
   Target.Capacity
   or else raise Capacity_Error),
```

- {*AI12-0112-1*} In the five-parameter procedure Copy_Subtree, the last **or else** of the precondition is replaced by: 11.3/5

```
(not Is_Root (Source, Subtree)                                           11.4/5
   or else raise Constraint_Error) and then
(Node_Count (Target) - 1 +
      Subtree_Node_Count (Source, Subtree) <= Target.Capacity
   or else raise Capacity_Error),
```

- {*AI12-0112-1*} In Copy_Local_Subtree, the last **or else** of the precondition is replaced by: 11.5/5

```
(not Is_Root (Source, Subtree)                                           11.6/5
   or else raise Constraint_Error) and then
(Node_Count (Target) - 1 +
      Subtree_Node_Count (Target, Source) <= Target.Capacity
   or else raise Capacity_Error),
```

- {*AI05-0136-1*} {*AI05-0248-1*} {*AI12-0112-1*} In the five-parameter procedure Splice_Subtree, the penultimate **or else** of the precondition is replaced by: 12/5

```
(Has_Element (Source, Position)                                          12.1/5
   or else raise Program_Error) and then
(Target'Has_Same_Storage (Source) or else
 Node_Count (Target) - 1 +
   Subtree_Node_Count (Source, Position) <= Target.Capacity
   or else raise Capacity_Error) and then
```

- {*AI05-0136-1*} {*AI05-0248-1*} {*AI12-0112-1*} In the five-parameter procedure Splice_Children, the penultimate **elsif** of the precondition is replaced by: 13/5

```
(Before = No_Element or else                                             13.1/5
 Parent (Target, Before) /= Target_Parent
   or else raise Constraint_Error) and then
(Target'Has_Same_Storage (Source) or else
 Node_Count (Target) - 1 +
   Child_Count (Source, Source_Parent) <= Target.Capacity
   or else raise Capacity_Error) and then
```

Bounded (Run-Time) Errors

{*AI05-0160-1*} {*AI05-0265-1*} It is a bounded error to assign from a bounded tree object while tampering with elements [or cursors] of that object is prohibited. Either Program_Error is raised by the assignment, execution proceeds with the target object prohibiting tampering with elements [or cursors], or execution proceeds normally. 14/3

14.a/3 **Proof:** Tampering with elements includes tampering with cursors, so we only really need to talk about tampering with elements here; we mention cursors for clarity.

Erroneous Execution

15/3 {*AI05-0265-1*} When a bounded tree object *T* is finalized, if tampering with cursors is prohibited for *T* other than due to an assignment from another tree, then execution is erroneous.

15.a/3 **Reason:** This is a tampering event, but since the implementation is not allowed to use Ada.Finalization, it is not possible in a pure Ada implementation to detect this error. (There is no Finalize routine that will be called that could make the check.) Since the check probably cannot be made, the bad effects that could occur (such as an iterator going into an infinite loop or accessing a nonexistent element) cannot be prevented and we have to allow anything. We do allow re-assigning an object that only prohibits tampering because it was copied from another object as that cannot cause any negative effects.

Implementation Requirements

16/3 {*AI05-0184-1*} {*AI05-0264-1*} For each instance of Containers.Multiway_Trees and each instance of Containers.Bounded_Multiway_Trees, if the two instances meet the following conditions, then the output generated by the Tree'Output or Tree'Write subprograms of either instance shall be readable by the Tree'Input or Tree'Read of the other instance, respectively:

17/3 - {*AI05-0184-1*} {*AI05-0248-1*} the Element_Type parameters of the two instances are statically matching subtypes of the same type; and

18/3 - {*AI05-0184-1*} the output generated by Element_Type'Output or Element_Type'Write is readable by Element_Type'Input or Element_Type'Read, respectively (where Element_Type denotes the type of the two actual Element_Type parameters).

Implementation Advice

19/3 {*AI05-0136-1*} Bounded tree objects should be implemented without implicit pointers or dynamic allocation.

19.a.1/3 **Implementation Advice:** Bounded tree objects should be implemented without implicit pointers or dynamic allocation.

20/3 {*AI05-0136-1*} The implementation advice for procedure Move to minimize copying does not apply.

20.a.1/3 **Implementation Advice:** The implementation advice for procedure Move to minimize copying does not apply to bounded trees.

Extensions to Ada 2005

20.a/3 {*AI05-0136-1*} {*AI05-0184-1*} The generic package Containers.Bounded_Multiway_Trees is new.

Inconsistencies With Ada 2012

20.b/5 {*AI12-0111-1*} **Correction:** Tampering with elements is now defined to be equivalent to tampering with cursors for bounded containers. If a program requires tampering detection to work, it might fail in Ada 2022. Needless to say, this shouldn't happen outside of test programs. See Inconsistencies With Ada 2012 in A.18.2 for more details.

Incompatibilities With Ada 2012

20.c/5 {*AI12-0409-1*} **Correction:**A bounded tree now only has Preelaborable_Initialization (abbreviated PI in this note) when the actual for the Element_Type has PI. If an program used a tree whose actual Element_Type does not have PI in a context when PI is required (such as a library-level object in a preelaborated unit or as a component of a type with PI), the program would be illegal in Ada 2022 but legal in original Ada 2012. This situation is unlikely, especially as some existing Ada 2012 implementations reject the instance in this case.

A.18.26 Array Sorting

{*AI95-00302-03*} {*AI05-0001-1*} The language-defined generic procedures Containers.Generic_-Array_Sort, Containers.Generic_Constrained_Array_Sort, and Containers.Generic_Sort provide sorting on arbitrary array types. 1/3

Static Semantics

{*AI95-00302-03*} The generic library procedure Containers.Generic_Array_Sort has the following declaration: 2/2

```
{AI12-0112-1} generic                                                    3/5
   type Index_Type is (<>);
   type Element_Type is private;
   type Array_Type is array (Index_Type range <>) of Element_Type;
   with function "<" (Left, Right : Element_Type)
      return Boolean is <>;
procedure Ada.Containers.Generic_Array_Sort (Container : in out Array_Type)
   with Pure, Nonblocking, Global => null;
```

Discussion: {*AI12-0112-1*} Global => **null** means that the only global side-effects allowed are associated with the actual generic parameters. Similarly, when Nonblocking is set to True for a generic unit, the only blocking allowed is that associated with the actual generic parameters. 3.a/5

Reorders the elements of Container such that the elements are sorted smallest first as determined by the generic formal "<" operator provided. Any exception raised during evaluation of "<" is propagated. 4/2

{*AI05-0044-1*} {*AI05-0262-1*} The actual function for the generic formal function "<" of Generic_Array_Sort is expected to return the same value each time it is called with a particular pair of element values. It should define a strict weak ordering relationship (see A.18); it should not modify Container. If the actual for "<" behaves in some other manner, the behavior of the instance of Generic_Array_Sort is unspecified. The number of times Generic_Array_Sort calls "<" is unspecified. 5/3

Ramification: This implies swapping the elements, usually including an intermediate copy. This of course means that the elements will be copied. Since the elements are nonlimited, this usually will not be a problem. Note that there is Implementation Advice below that the implementation should use a sort that minimizes copying of elements. 5.a/2

The sort is not required to be stable (and the fast algorithm required will not be stable). If a stable sort is needed, the user can include the original location of the element as an extra "sort key". We considered requiring the implementation to do that, but it is mostly extra overhead -- usually there is something already in the element that provides the needed stability. 5.b/2

{*AI95-00302-03*} The generic library procedure Containers.Generic_Constrained_Array_Sort has the following declaration: 6/2

```
{AI12-0112-1} generic                                                    7/5
   type Index_Type is (<>);
   type Element_Type is private;
   type Array_Type is array (Index_Type) of Element_Type;
   with function "<" (Left, Right : Element_Type)
      return Boolean is <>;
procedure Ada.Containers.Generic_Constrained_Array_Sort
      (Container : in out Array_Type)
   with Pure, Nonblocking, Global => null;
```

Discussion: {*AI12-0112-1*} Global => **null** means that the only global side-effects allowed are associated with the actual generic parameters. Similarly, when Nonblocking is set to True for a generic unit, the only blocking allowed is that associated with the actual generic parameters. 7.a/5

Reorders the elements of Container such that the elements are sorted smallest first as determined by the generic formal "<" operator provided. Any exception raised during evaluation of "<" is propagated. 8/2

9/3 {*AI05-0044-1*} {*AI05-0262-1*} The actual function for the generic formal function "<" of Generic_Constrained_Array_Sort is expected to return the same value each time it is called with a particular pair of element values. It should define a strict weak ordering relationship (see A.18); it should not modify Container. If the actual for "<" behaves in some other manner, the behavior of the instance of Generic_Constrained_Array_Sort is unspecified. The number of times Generic_Constrained_Array_Sort calls "<" is unspecified.

9.1/3 {*AI05-0001-1*} The generic library procedure Containers.Generic_Sort has the following declaration:

9.2/5
```
{AI12-0056-1} {AI12-0112-1} generic
   type Index_Type is (<>);
   with function Before (Left, Right : Index_Type) return Boolean;
   with procedure Swap (Left, Right : in Index_Type);
procedure Ada.Containers.Generic_Sort
      (First, Last : Index_Type'Base)
   with Pure, Nonblocking, Global => null;
```

9.a/5 **Discussion:** {*AI12-0112-1*} Global => **null** means that the only global side-effects allowed are associated with the actual generic parameters. Similarly, when Nonblocking is set to True for a generic unit, the only blocking allowed is that associated with the actual generic parameters.

9.3/3 {*AI05-0001-1*} {*AI05-0248-1*} Reorders the elements of an indexable structure, over the range First .. Last, such that the elements are sorted in the ordering determined by the generic formal function Before; Before should return True if Left is to be sorted before Right. The generic formal Before compares the elements having the given indices, and the generic formal Swap exchanges the values of the indicated elements. Any exception raised during evaluation of Before or Swap is propagated.

9.4/3 The actual function for the generic formal function Before of Generic_Sort is expected to return the same value each time it is called with index values that identify a particular pair of element values. It should define a strict weak ordering relationship (see A.18); it should not modify the elements. The actual function for the generic formal Swap should exchange the values of the indicated elements. If the actual for either Before or Swap behaves in some other manner, the behavior of Generic_Sort is unspecified. The number of times the Generic_Sort calls Before or Swap is unspecified.

Implementation Advice

10/2 {*AI95-00302-03*} The worst-case time complexity of a call on an instance of Containers.Generic_Array_Sort or Containers.Generic_Constrained_Array_Sort should be $O(N^{**}2)$ or better, and the average time complexity should be better than $O(N^{**}2)$, where N is the length of the Container parameter.

10.a/2 **Implementation Advice:** Containers.Generic_Array_Sort and Containers.Generic_Constrained_Array_Sort should have an average time complexity better than $O(N^{**}2)$ and worst case no worse than $O(N^{**}2)$.

10.b/2 **Discussion:** In other words, we're requiring the use of a sorting algorithm better than $O(N^{**}2)$, such as Quicksort. No bubble sorts allowed!

11/2 {*AI95-00302-03*} Containers.Generic_Array_Sort and Containers.Generic_Constrained_Array_Sort should minimize copying of elements.

11.a/2 **Implementation Advice:** Containers.Generic_Array_Sort and Containers.Generic_Constrained_Array_Sort should minimize copying of elements.

11.b/2 **To be honest:** We do not mean “absolutely minimize” here; we're not intending to require a single copy for each element. Rather, we want to suggest that the sorting algorithm chosen is one that does not copy items unnecessarily. Bubble sort would not meet this advice, for instance.

12/3 {*AI05-0248-1*} The worst-case time complexity of a call on an instance of Containers.Generic_Sort should be $O(N^{**}2)$ or better, and the average time complexity should be better than $O(N^{**}2)$, where N is the difference between the Last and First parameters plus 1.

Implementation Advice: Containers.Generic_Sort should have an average time complexity better than *O*(*N***2) and worst case no worse than *O*(*N***2). 12.a.1/3

{*AI05-0248-1*} Containers.Generic_Sort should minimize calls to the generic formal Swap. 13/3

Implementation Advice: Containers.Generic_Sort should minimize calls to the generic formal Swap. 13.a.1/3

Extensions to Ada 95

{*AI95-00302-03*} The generic procedures Containers.Generic_Array_Sort and Containers.Generic_Constrained_Array_Sort are new. 13.a/2

Extensions to Ada 2005

{*AI05-0001-1*} {*AI05-0248-1*} The generic procedure Containers.Generic_Sort is new. 13.b/3

Wording Changes from Ada 2005

{*AI05-0044-1*} **Correction:** Redefined "<" actuals to require a strict weak ordering; the old definition allowed indeterminant comparisons that would not have worked in a sort. 13.c/3

Wording Changes from Ada 2012

{*AI12-0112-1*} Added contracts to these procedures. 13.d/5

A.18.27 The Generic Package Containers.Synchronized_Queue_Interfaces

{*AI05-0159-1*} The language-defined generic package Containers.Synchronized_Queue_Interfaces provides interface type Queue, and a set of operations for that type. Interface Queue specifies a first-in, first-out queue. 1/3

Static Semantics

{*AI05-0159-1*} The generic library package Containers.Synchronized_Queue_Interfaces has the following declaration: 2/3

```
{AI12-0112-1} generic                                                                    3/5
   type Element_Type is private;
package Ada.Containers.Synchronized_Queue_Interfaces
   with Pure, Nonblocking, Global => null is
```

Discussion: {*AI12-0112-1*} Global => **null** means that the only global side-effects allowed are associated with the actual generic parameters. Similarly, when Nonblocking is set to True for a generic unit, the only blocking allowed is that associated with the actual generic parameters. 3.a/5

```
   type Queue is synchronized interface;                                                 4/3

{AI12-0112-1}    procedure Enqueue                                                       5/5
     (Container : in out Queue;
      New_Item  : in     Element_Type) is abstract
       with Synchronization => By_Entry,
            Nonblocking => False,
            Global'Class=> in out synchronized;

{AI12-0112-1}    procedure Dequeue                                                       6/5
     (Container : in out Queue;
      Element   :    out Element_Type) is abstract
       with Synchronization => By_Entry,
            Nonblocking => False,
            Global'Class=> in out synchronized;

{AI12-0112-1}    function Current_Use (Container : Queue) return Count_Type is          7/5
abstract
       with Nonblocking, Global'Class => null, Use_Formal => null;
   function Peak_Use (Container : Queue) return Count_Type is abstract
       with Nonblocking, Global'Class => null, Use_Formal => null,
            Post'Class => Peak_Use'Result >= Current_Use (Container);
```

8/3
```
end Ada.Containers.Synchronized_Queue_Interfaces;
```

8.1/5 {*AI12-0112-1*} The subprogram behavior descriptions given below are the semantics for the corresponding callable entities found in the language-defined generic packages that have a formal package named Queue_Interfaces.

9/5
```
{AI12-0112-1} procedure Enqueue
  (Container : in out Queue;
   New_Item  : in     Element_Type) is abstract
   with Synchronization => By_Entry
        Nonblocking => False,
        Global'Class=> in out synchronized;
```

10/3 {*AI05-0159-1*} {*AI05-0262-1*} {*AI05-0264-1*} A queue type that implements this interface is allowed to have a bounded *capacity*. If the queue object has a bounded capacity, and the number of existing elements equals the capacity, then Enqueue blocks until storage becomes available; otherwise, Enqueue does not block. In any case, it then copies New_Item onto the queue.

11/5
```
{AI12-0112-1} procedure Dequeue
  (Container : in out Queue;
   Element   :    out Element_Type) is abstract
   with Synchronization => By_Entry
        Nonblocking => False,
        Global'Class=> in out synchronized;
```

12/3 {*AI05-0159-1*} {*AI05-0251-1*} If the queue is empty, then Dequeue blocks until an item becomes available. In any case, it then assigns the element at the head of the queue to Element, and removes it from the queue.

13/5
```
{AI12-0112-1} function Current_Use (Container : Queue) return Count_Type is
abstract
   with Nonblocking, Global'Class=> null, Use_Formal => null;
```

14/3 {*AI05-0159-1*} Returns the number of elements currently in the queue.

15/5
```
{AI12-0112-1} function Peak_Use (Container : Queue) return Count_Type is abstract
   with Nonblocking, Global'Class=> null, Use_Formal => null,
         Post'Class => Peak_Use'Result >= Current_Use (Container);
```

16/3 {*AI05-0159-1*} Returns the maximum number of elements that have been in the queue at any one time.

17/3 NOTE {*AI05-0251-1*} Unlike other language-defined containers, there are no queues whose element types are indefinite. Elements of an indefinite type can be handled by defining the element of the queue to be a holder container (see A.18.18) of the indefinite type, or to be an explicit access type that designates the indefinite type.

17.a/3 **Reason:** There are no indefinite queues, as a useful definition for Dequeue is not possible. Dequeue cannot be a function, as Ada does not have entries that are functions (thus conditional and timed calls would not be possible). Moreover, protected functions do not allow modifying the queue object (thus it doesn't work even if we decided we didn't care about conditional and timed calls). If Dequeue is an entry, then the dequeued object would have to be an **out** parameter and that would require the queue client to guess the tag and constraints of the value that will be dequeued (otherwise Constraint_Error would be raised), and that is rarely going to be possible.

Extensions to Ada 2005

17.b/3 {*AI05-0159-1*} {*AI05-0251-1*} The generic package Containers.Synchronized_Queue_Interfaces is new.

A.18.28 The Generic Package Containers.Unbounded_Synchronized_Queues

Static Semantics

{*AI05-0159-1*} The language-defined generic package Containers.Unbounded_Synchronized_Queues provides type Queue, which implements the interface type Containers.Synchronized_Queue_Interfaces.Queue. 1/3

```
{AI12-0112-1} with System;                                                    2/5
with Ada.Containers.Synchronized_Queue_Interfaces;
generic
   with package Queue_Interfaces is
      new Ada.Containers.Synchronized_Queue_Interfaces (<>);
   Default_Ceiling : System.Any_Priority := System.Priority'Last;
package Ada.Containers.Unbounded_Synchronized_Queues
   with Preelaborate,
        Nonblocking, Global => in out synchronized is
```

Discussion: {*AI12-0112-1*} For discussion on the reasons and meaning of the specifications of the Global and Nonblocking aspects of this generic package, see the notes on the specification of the Containers.Vectors package (see A.18.2). 2.a/5

```
   package Implementation is                                                  3/3
      ... -- not specified by the language
   end Implementation;

   protected type Queue                                                       4/3
        (Ceiling : System.Any_Priority := Default_Ceiling)
           with Priority => Ceiling is
        new Queue_Interfaces.Queue with

      overriding                                                              5/3
      entry Enqueue (New_Item : in Queue_Interfaces.Element_Type);
      overriding
      entry Dequeue (Element : out Queue_Interfaces.Element_Type);

{AI12-0112-1}       overriding                                              6/5
      function Current_Use return Count_Type
         with Nonblocking, Global => null, Use_Formal => null;
      overriding
      function Peak_Use return Count_Type
         with Nonblocking, Global => null, Use_Formal => null;

   private                                                                    7/3
      ... -- not specified by the language
   end Queue;

private                                                                       8/3

   ... -- not specified by the language                                       9/3

end Ada.Containers.Unbounded_Synchronized_Queues;                             10/3
```

{*AI05-0159-1*} The type Queue is used to represent task-safe queues. 11/3

{*AI05-0159-1*} The capacity for instances of type Queue is unbounded. 12/3

Ramification: Enqueue never blocks; if more storage is needed for a new element, it is allocated dynamically. We don't need to explicitly specify that Queue needs finalization, because it is visibly protected. 12.a/3

Discussion: Nested package Implementation can be used to declare the types needed to implement the protected type Queue. This nested package is necessary as types cannot be declared in the private part of a protected type, and the types have to be declared within the generic unit in order to depend on the types imported with package Queue_Interfaces. Clients should never depend on the contents of nested package Implementation. 12.b/3

Extensions to Ada 2005

{*AI05-0159-1*} The generic package Containers.Unbounded_Synchronized_Queues is new. 12.c/3

A.18.29 The Generic Package Containers.Bounded_Synchronized_Queues

Static Semantics

1/3 {*AI05-0159-1*} The language-defined generic package Containers.Bounded_Synchronized_Queues provides type Queue, which implements the interface type Containers.Synchronized_Queue_Interfaces.Queue.

2/5
```
{AI12-0112-1} with System;
with Ada.Containers.Synchronized_Queue_Interfaces;
generic
   with package Queue_Interfaces is
      new Ada.Containers.Synchronized_Queue_Interfaces (<>);
   Default_Capacity : Count_Type;
   Default_Ceiling  : System.Any_Priority := System.Priority'Last;
package Ada.Containers.Bounded_Synchronized_Queues
   with Preelaborate,
        Nonblocking, Global => in out synchronized is
```

2.a/5 **Discussion:** {*AI12-0112-1*} For discussion on the reasons and meaning of the specifications of the Global and Nonblocking aspects of this generic package, see the notes on the specification of the Containers.Vectors package (see A.18.2).

3/3
```
   package Implementation is
      ... -- not specified by the language
   end Implementation;
```

4/3
```
   protected type Queue
        (Capacity : Count_Type := Default_Capacity;
         Ceiling  : System.Any_Priority := Default_Ceiling)
           with Priority => Ceiling is
        new Queue_Interfaces.Queue with
```

5/3
```
      overriding
      entry Enqueue (New_Item : in Queue_Interfaces.Element_Type);
      overriding
      entry Dequeue (Element : out Queue_Interfaces.Element_Type);
```

6/5
```
   {AI12-0112-1}      overriding
      function Current_Use return Count_Type
         with Nonblocking, Global => null, Use_Formal => null;
      overriding
      function Peak_Use return Count_Type
         with Nonblocking, Global => null, Use_Formal => null;
```

7/3
```
   private
      ... -- not specified by the language
   end Queue;
```

8/3
```
private
```

9/3
```
   ... -- not specified by the language
```

10/3
```
end Ada.Containers.Bounded_Synchronized_Queues;
```

11/3 {*AI05-0159-1*} The semantics are the same as for Unbounded_Synchronized_Queues, except:

12/3 - The capacity for instances of type Queue is bounded and specified by the discriminant Capacity.

12.a/3 **Ramification:** Since this type has a bounded capacity, Enqueue might block if the queue is full.

Implementation Advice

13/3 {*AI05-0159-1*} Bounded queue objects should be implemented without implicit pointers or dynamic allocation.

13.a.1/3 **Implementation Advice:** Bounded queue objects should be implemented without implicit pointers or dynamic allocation.

        (At_Least : in     Queue_Priority;
         Element  : in out Queue_Interfaces.Element_Type;
         Success  :    out Boolean);

{AI12-0112-1}       overriding                                              7/5
      function Current_Use return Count_Type
         with Nonblocking, Global => null, Use_Formal => null;
      overriding
      function Peak_Use return Count_Type
         with Nonblocking, Global => null, Use_Formal => null;

   private                                                                    8/3
      ... -- not specified by the language
   end Queue;

private                                                                       9/3

   ... -- not specified by the language                                       10/3

end Ada.Containers.Unbounded_Priority_Queues;                                 11/3
```

{*AI05-0159-1*} The type Queue is used to represent task-safe priority queues. 12/3

{*AI05-0159-1*} The capacity for instances of type Queue is unbounded. 13/3

14/3 {*AI05-0159-1*} Two elements *E1* and *E2* are equivalent if Before(Get_Priority(*E1*), Get_Priority(*E2*)) and Before(Get_Priority(*E2*), Get_Priority(*E1*)) both return False.

15/3 {*AI05-0159-1*} {*AI05-0248-1*} The actual functions for Get_Priority and Before are expected to return the same value each time they are called with the same actuals, and should not modify their actuals. Before should define a strict weak ordering relationship (see A.18). If the actual functions behave in some other manner, the behavior of Unbounded_Priority_Queues is unspecified.

16/3 {*AI05-0159-1*} Enqueue inserts an item according to the order specified by the Before function on the result of Get_Priority on the elements; Before should return True if Left is to be inserted before Right. If the queue already contains elements equivalent to New_Item, then it is inserted after the existing equivalent elements.

16.a/3 **Ramification:** Enqueue never blocks; if more storage is needed for a new element, it is allocated dynamically. We don't need to explicitly specify that Queue needs finalization, because it is visibly protected.

17/3 {*AI05-0159-1*} {*AI05-0251-1*} {*AI05-0262-1*} For a call on Dequeue_Only_High_Priority, if the head of the nonempty queue is *E*, and the function Before(At_Least, Get_Priority(*E*)) returns False, then *E* is assigned to Element and then removed from the queue, and Success is set to True; otherwise, Success is set to False and Element is unchanged.

17.a/3 **Ramification:** {*AI05-0251-1*} Unlike Dequeue, Dequeue_Only_High_Priority is not blocking; it always returns immediately.

17.b/3 **Reason:** {*AI05-0251-1*} The use of Before is "backwards" so that it acts like ">=" (it is defined similarly to ">"); thus we dequeue only when it is False.

Extensions to Ada 2005

17.c/3 {*AI05-0159-1*} {*AI05-0251-1*} The generic package Containers.Unbounded_Priority_Queues is new.

A.18.31 The Generic Package Containers.Bounded_Priority_Queues

Static Semantics

1/3 {*AI05-0159-1*} The language-defined generic package Containers.Bounded_Priority_Queues provides type Queue, which implements the interface type Containers.Synchronized_Queue_Interfaces.Queue.

2/5
```
{AI12-0112-1} with System;
with Ada.Containers.Synchronized_Queue_Interfaces;
generic
   with package Queue_Interfaces is
      new Ada.Containers.Synchronized_Queue_Interfaces (<>);
   type Queue_Priority is private;
   with function Get_Priority

```

{*AI05-0159-1*} The semantics are the same as for Unbounded_Priority_Queues, except: 12/3

- The capacity for instances of type Queue is bounded and specified by the discriminant Capacity. 13/3

  Ramification: Since this type has a bounded capacity, Enqueue might block if the queue is full. 13.a/3

Implementation Advice

{*AI05-0159-1*} Bounded priority queue objects should be implemented without implicit pointers or dynamic allocation. 14/3

Implementation Advice: Bounded priority queue objects should be implemented without implicit pointers or dynamic allocation. 14.a.1/3

Extensions to Ada 2005

{*AI05-0159-1*} {*AI05-0251-1*} The generic package Containers.Bounded_Priority_Queues is new. 14.a/3

A.18.32 The Generic Package Containers.Bounded_Indefinite_Holders

{*AI12-0254-1*} The language-defined generic package Containers.Bounded_Indefinite_Holders provides a private type Holder and a set of operations for that type. It provides the same operations as the package Containers.Indefinite_Holders (see A.18.18), with the difference that the maximum storage is bounded. 1/5

Static Semantics

{*AI12-0254-1*} The declaration of the generic library package Containers.Bounded_Indefinite_Holders has the same contents and semantics as Containers.Indefinite_Holders except: 2/5

- The following is added to the context clause: 3/5

```
with System.Storage_Elements; use System.Storage_Elements;                4/5
```

- An additional generic parameter follows Element_Type: 5/5

```
Max_Element_Size_in_Storage_Elements : Storage_Count;                      6/5
```

6.a/5 **Reason:** This value is in Storage_Elements so that it can be used as a discriminant on a storage pool object in the implementation of the object; Ada doesn't allow discriminant dependent components to use formulas.

6.b/5 This is a generic parameter as it is a property of the Element_Type; the largest possible object of Element_Type is unlikely to be different for different containers, so making it a discriminant (as Capacity is) provides no useful capability.

7/5 - {*AI12-0409-1*} The aspect_definition for Preelaborable_Initialization for type Holder is changed to:

8/5
```
Preelaborable_Initialization =>
   Element_Type'Preelaborable_Initialization
```

9/5 - Add to the precondition of To_Holder and Replace_Element:

10/5
```
and then (New_Item'Size <=
             Max_Element_Size_in_Storage_Elements * System.Storage_Unit
          or else raise Program_Error)
```

10.a/5 **Reason:** This ensures that an object that won't fit is not inserted into the container.

Bounded (Run-Time) Errors

11/5 {*AI12-0254-1*} It is a bounded error to assign from a bounded holder object while tampering with elements of that object is prohibited. Either Program_Error is raised by the assignment, execution proceeds with the target object prohibiting tampering with elements, or execution proceeds normally.

Implementation Requirements

12/5 {*AI12-0254-1*} For each instance of Containers.Indefinite_Holders and each instance of Containers.Bounded_Indefinite_Holders, if the two instances meet the following conditions, then the output generated by the Holder'Output or Holder'Write subprograms of either instance shall be readable by the Holder'Input or Holder'Read of the other instance, respectively:

13/5 - the Element_Type parameters of the two instances are statically matching subtypes of the same type; and

14/5 - the output generated by Element_Type'Output or Element_Type'Write is readable by Element_Type'Input or Element_Type'Read, respectively (where Element_Type denotes the type of the two actual Element_Type parameters).

Implementation Advice

15/5 {*AI12-0254-1*} Bounded holder objects should be implemented without dynamic allocation and any finalization should be trivial unless Element_Type needs finalization.

15.a.1/5 **Implementation Advice:** Bounded holder objects should be implemented without dynamic allocation.

15.a/5 **To be honest:** Implementation of this container in Ada will probably require the use of a special storage pool. When we say "without dynamic allocation", we mean that this pool does not use heap memory and has a trivial finalization routine (that is, procedures Adjust and Finalize are null procedures). All storage pools are controlled, so we can't reasonably say that a bounded holder will not need finalization.

15.b/5 **Implementation Note:** If the implementation supports discontiguous objects that require multiple calls to Allocate in a storage pool, the storage pool will need to support such allocations. The storage pool implementation can assume that all Allocate calls occur together, and similarly for Deallocate calls, thus simplifying the pool implementation so that allocation only occurs at a high-water mark location.

16/5 {*AI12-0350-1*} {*AI12-0445-1*} The Implementation Advice about the Move and Swap operations is deleted for bounded holders; these operations can copy elements as necessary.

16.a/5 **Reason:** The memory of a bounded indefinite holder belongs directly to the container, so it cannot be moved with the element. If the element type contains any internal pointers, moving it without calling Adjust would leave such pointers pointing to the wrong holder object. Thus, a full copy is needed, including any associated finalization and adjustments.

Extensions to Ada 2012

16.b/5 {*AI12-0254-1*} The generic package Containers.Bounded_Indefinite_Holders is new.

A.18.33 Example of Container Use

Examples

{*AI05-0212-1*} The following example is an implementation of Dijkstra's shortest path algorithm in a directed graph with positive distances. The graph is represented by a map from nodes to sets of edges. 1/3

```
with Ada.Containers.Vectors;                                                    2/3
with Ada.Containers.Doubly_Linked_Lists;
use Ada.Containers;
generic
   type Node is range <>;
package Shortest_Paths is
   type Distance is new Float range 0.0 .. Float'Last;
   type Edge is record
      To, From : Node;
      Length   : Distance;
   end record;

   package Node_Maps is new Vectors (Node, Node);                               3/3
   -- The algorithm builds a map to indicate the node used to reach a given
   -- node in the shortest distance.

   package Adjacency_Lists is new Doubly_Linked_Lists (Edge);                   4/3
   use Adjacency_Lists;

   package Graphs is new Vectors (Node, Adjacency_Lists.List);                  5/3

   package Paths is new Doubly_Linked_Lists (Node);                             6/3

   function Shortest_Path                                                       7/3
     (G : Graphs.Vector; Source : Node; Target : Node) return Paths.List
      with Pre => G (Source) /= Adjacency_Lists.Empty_List;

end Shortest_Paths;                                                             8/3

{AI12-0178-1} package body Shortest_Paths is                                    9/5
   function Shortest_Path
     (G : Graphs.Vector; Source : Node; Target : Node) return Paths.List
   is
      use Node_Maps, Paths, Graphs;
      Reached  : array (Node) of Boolean := (others => False);
      -- The set of nodes whose shortest distance to the source is known.

{AI05-0299-1}       Reached_From : array (Node) of Node;                        10/3
      So_Far   : array (Node) of Distance := (others => Distance'Last);
      The_Path : Paths.List := Paths.Empty_List;
      Nearest_Distance : Distance;
      Next     : Node;
   begin
      So_Far(Source)  := 0.0;

      while not Reached(Target) loop                                            11/3
         Nearest_Distance := Distance'Last;

         -- Find closest node not reached yet, by iterating over all nodes.     12/3
         -- A more efficient algorithm uses a priority queue for this step.

         Next := Source;                                                        13/3
         for N in Node'First .. Node'Last loop
            if not Reached(N)
              and then So_Far(N) < Nearest_Distance then
                 Next := N;
                 Nearest_Distance := So_Far(N);
            end if;
         end loop;

{AI05-0299-1}          if Nearest_Distance = Distance'Last then                 14/3
            -- No next node found, graph is not connected
            return Paths.Empty_List;
```

```
15/3              else
                     Reached(Next) := True;
                  end if;
16/3              -- Update minimum distance to newly reachable nodes.
17/3        {AI05-0299-1}          for E of G (Next) loop
                  if not Reached(E.To) then
                     Nearest_Distance := E.Length + So_Far(Next);
18/3                 if Nearest_Distance < So_Far(E.To) then
                        Reached_From(E.To) := Next;
                        So_Far(E.To) := Nearest_Distance;
                     end if;
                  end if;
               end loop;
            end loop;
19/3        -- Rebuild path from target to source.
20/5        {AI12-0386-1}       declare
               N : Node := Target;
            begin
               Prepend (The_Path, N);
               while N /= Source loop
                  N := Reached_From(N);
                  Prepend (The_Path, N);
               end loop;
            end;
21/3        return The_Path;
         end;
      end Shortest_Paths;
```

22/3 {*AI05-0212-1*} Note that the effect of the Constant_Indexing aspect (on type Vector) and the Implicit_Dereference aspect (on type Reference_Type) is that

```
23/3    G (Next)
```

24/5 {*AI05-0212-1*} {*AI12-0426-1*} is a convenient shorthand for

```
25/3    G.Constant_Reference (Next).Element.all
```

26/3 {*AI05-0212-1*} Similarly, the effect of the loop:

```
27/3    for E of G (Next) loop
           if not Reached(E.To) then
              ...
           end if;
        end loop;
```

28/3 {*AI05-0212-1*} is the same as:

```
29/4    {AI12-0080-1} for C in G (Next).Iterate loop
           declare
              E : Edge renames G (Next)(C);
           begin
              if not Reached(E.To) then
                 ...
              end if;
           end;
        end loop;
```

{*AI05-0212-1*} which is the same as: 30/3

```
{AI12-0080-1} declare                                                    31/4
   L : Adjacency_Lists.List renames G (Next);
   C : Adjacency_Lists.Cursor := L.First;
begin
   while Has_Element (C) loop
      declare
         E : Edge renames L(C);
      begin
         if not Reached(E.To) then
            ...
         end if;
      end;
      C := L.Next (C);
   end loop;
end;
```

Wording Changes from Ada 2005

{*AI05-0212-1*} This example of container use is new. 31.a/3

A.19 The Package Locales

{*AI05-0127-2*} {*AI05-0248-1*} A *locale* identifies a geopolitical place or region and its associated language, which can be used to determine other internationalization-related characteristics. 1/3

Static Semantics

{*AI05-0127-2*} The library package Locales has the following declaration: 2/3

```
{AI12-0414-1} package Ada.Locales                                        3/5
   with Preelaborate, Remote_Types is

{AI12-0037-1}    type Language_Code is new String (1 .. 3)               4/4
      with Dynamic_Predicate =>
         (for all E of Language_Code => E in 'a' .. 'z');
   type Country_Code is new String (1 .. 2)
      with Dynamic_Predicate =>
         (for all E of Country_Code  => E in 'A' .. 'Z');
```

Discussion: {*AI12-0037-1*} These types are derived from type String so that they can easily be converted to or from type String. That's important if one of these values needs to be input or displayed (via Text_IO, perhaps). We use the predicate to ensure that only possible component values are used. Ada does not allow converting between unrelated types with components that don't statically match, so we cannot declare new types with constrained components if we want conversions to or from type String. 4.a/4

```
   Language_Unknown : constant Language_Code := "und";                   5/3
   Country_Unknown : constant Country_Code := "ZZ";

   function Language return Language_Code;                               6/3
   function Country return Country_Code;

end Ada.Locales;                                                         7/3
```

{*AI05-0127-2*} {*AI05-0233-1*} The *active locale* is the locale associated with the partition of the current task. 8/3

Implementation Note: {*AI05-0233-1*} Some environments define both a system locale and the locale of the current user. For such environments, the active locale is that of current user if any; otherwise (as in a partition running on a server without a user), the system locale should be used. 8.a/3

This paragraph was deleted.{*AI05-0127-2*} {*AI12-0446-1*} 9/5

This paragraph was deleted.{*AI05-0127-2*} {*AI12-0446-1*} 10/5

{*AI05-0127-2*} {*AI05-0248-1*} {*AI12-0446-1*} Function Language returns the code of the language associated with the active locale. If the Language_Code associated with the active locale cannot be 11/5

determined from the environment, then Language returns Language_Unknown. Otherwise, the result is a lower-case string representation of an ISO 639-3:2007 alpha-3 code that identifies a language.

11.a/3 **Discussion:** Some common language codes are: "eng" – English; "fra" – French; "deu" – German; "zho" – Chinese. These are the same codes as used by POSIX systems. We considered including constants for the most common languages, but that was rejected as the likely source of continual arguments about the constant names and which languages are important enough to include.

12/5 {*AI05-0127-2*} {*AI05-0248-1*} {*AI12-0446-1*} {*AI12-0450-1*} Function Country returns the code of the country associated with the active locale. If the Country_Code associated with the active locale cannot be determined from the environment, then Country returns Country_Unknown. Otherwise, the result is an upper-case string representation of an ISO 3166-1:2020 alpha-2 code that identifies a country.

12.a/3 **Discussion:** Some common country codes are: "CA" – Canada; "FR" – France; "DE" – Germany; "IT" – Italy; "ES" – Spain; "GB" – United Kingdom; "US" – United States. These are the same codes as used by POSIX systems. We didn't include any country constants for the same reasons that we didn't include any language constants.

Extensions to Ada 2005

12.b/3 {*AI05-0127-2*} {*AI05-0233-1*} Package Locales is new.

Inconsistencies With Ada 2012

12.c/4 {*AI12-0037-1*} **Corrigendum:** Types Language_Code and Country_Code are defined with predicates rather than constrained components so that they can be converted to/from type String. This changes the exception raised from Constraint_Error to Assertion_Error if an assignment is attempted with an incorrect value. This could only matter if there is a handler specifically for Constraint_Error surrounding this assignment; as this exception raise is certainly caused by a bug (why would anyone want to use invalid language or country codes?), such a handler seems very unlikely. (In addition, this is a new Ada 2012 package, so there is not likely to be a lot of code using it.)

Annex B
(normative)
Interface to Other Languages

This Annex describes features for writing mixed-language programs. General interface support is presented first; then specific support for C, COBOL, and Fortran is defined, in terms of language interface packages for each of these languages. 1

Ramification: This Annex is not a "Specialized Needs" annex. Every implementation must support all nonoptional features defined here (mainly the package Interfaces). 1.a

Language Design Principles

Ada should have strong support for mixed-language programming. 1.b

Implementation Requirements

{*AI05-0229-1*} {*AI05-0262-1*} {*AI05-0299-1*} Support for interfacing to any foreign language is optional. However, an implementation shall not provide any optional aspect, attribute, library unit, or pragma having the same name as an aspect, attribute, library unit, or pragma (respectively) specified in the subclauses of this Annex unless the provided construct is either as specified in those subclauses or is more limited in capability than that required by those subclauses. A program that attempts to use an unsupported capability of this Annex shall either be identified by the implementation before run time or shall raise an exception at run time. 2/3

Discussion: The intent is that the same rules apply for the optional parts of language interfacing as apply for Specialized Needs Annexes. See 1.1.3 for a discussion of the purpose of these rules. 2.a/3

Extensions to Ada 83

Much of the functionality in this Annex is new to Ada 95. 2.b

Wording Changes from Ada 83

This Annex contains what used to be RM83-13.8. 2.c

Wording Changes from Ada 2005

{*AI05-0262-1*} Moved the clarification that interfacing to foreign languages is optional and has the same restrictions as a Specialized Needs Annex here. 2.d/3

B.1 Interfacing Aspects

{*AI05-0229-1*} An *interfacing* aspect is a representation aspect that is one of the aspects Import, Export, Link_Name, External_Name, or Convention. 0.1/3

{*AI05-0229-1*} {*AI05-0269-1*} Specifying the Import aspect to have the value True is used to import an entity defined in a foreign language into an Ada program, thus allowing a foreign-language subprogram to be called from Ada, or a foreign-language variable to be accessed from Ada. In contrast, specifying the Export aspect to have the value True is used to export an Ada entity to a foreign language, thus allowing an Ada subprogram to be called from a foreign language, or an Ada object to be accessed from a foreign language. The Import and Export aspects are intended primarily for objects and subprograms, although implementations are allowed to support other entities. The Link_Name and External_Name aspects are used to specify the link name and external name, respectively, to be used to identify imported or exported entities in the external environment. 1/3

Aspect Description for Import: Entity is imported from another language. 1.a/3

1.b/3 **Aspect Description for Export:** Entity is exported to another language.

1.c/3 **Aspect Description for External_Name:** Name used to identify an imported or exported entity.

1.d/3 **Aspect Description for Link_Name:** Linker symbol used to identify an imported or exported entity.

2/3 {*AI05-0229-1*} The Convention aspect is used to indicate that an Ada entity should use the conventions of another language. It is intended primarily for types and "callback" subprograms. For example, "**with** Convention => Fortran" on the declaration of an array type Matrix implies that Matrix should be represented according to the conventions of the supported Fortran implementation, namely column-major order.

2.a/3 **Aspect Description for Convention:** Calling convention or other convention used for interfacing to other languages.

3/5 {*AI12-0445-1*} A pragma Linker_Options is used to specify the system linker parameters necessary when a given compilation unit is included in a partition.

Syntax

4/3 {*AI05-0229-1*} The form of a pragma Linker_Options is as follows:

Paragraphs 5 through 7 were moved to Annex J, "Obsolescent Features".

8 **pragma** Linker_Options(*string*_expression);

9 A pragma Linker_Options is allowed only at the place of a declarative_item.

9.1/3 *This paragraph was deleted.*{*8652/0058*} {*AI95-00036-01*} {*AI05-0229-1*}

Name Resolution Rules

9.2/3 {*AI05-0229-1*} The Import and Export aspects are of type Boolean.

10/3 {*AI05-0229-1*} The Link_Name and External_Name aspects are of type String.

10.a/3 **Ramification:** There is no language-defined support for external or link names of type Wide_String, or of other string types. Implementations may, of course, have additional aspects for that purpose. Note that allowing both String and Wide_String in the same aspect_definition would cause ambiguities.

10.1/3 {*AI05-0229-1*} The expected type for the *string*_expression in pragma Linker_Options is String.

Legality Rules

11/3 {*AI05-0229-1*} The aspect Convention shall be specified by a *convention*_identifier which shall be the name of a *convention*. The convention names are implementation defined, except for certain language-defined ones, such as Ada and Intrinsic, as explained in 6.3.1, "Conformance Rules". [Additional convention names generally represent the calling conventions of foreign languages, language implementations, or specific run-time models.] The convention of a callable entity is its *calling convention*.

11.a **Implementation defined:** Implementation-defined convention names.

11.b **Discussion:** We considered representing the convention names using an enumeration type declared in System. Then, *convention*_identifier would be changed to *convention*_name, and we would make its expected type be the enumeration type. We didn't do this because it seems to introduce extra complexity, and because the list of available languages is better represented as the list of children of package Interfaces — a more open-ended sort of list.

12 If *L* is a *convention*_identifier for a language, then a type T is said to be *compatible with convention L*, (alternatively, is said to be an *L-compatible type*) if any of the following conditions are met:

13 • T is declared in a language interface package corresponding to *L* and is defined to be *L*-compatible (see B.3, B.3.1, B.3.2, B.4, B.5),

14/3 • {*AI05-0229-1*} Convention *L* has been specified for T, and T is *eligible for convention L*; that is:

- {*AI12-0135-1*} T is an enumeration type such that all internal codes (whether assigned by default or explicitly) are within an implementation-defined range that includes at least the range of values 0 .. 2**15–1; 14.1/4
- T is an array type with either an unconstrained or statically-constrained first subtype, and its component type is *L*-compatible, 15
- T is a record type that has no discriminants and that only has components with statically-constrained subtypes, and each component type is *L*-compatible, 16
- {*AI05-0002-1*} T is an access-to-object type, its designated type is *L*-compatible, and its designated subtype is not an unconstrained array subtype, 17/3
- T is an access-to-subprogram type, and its designated profile's parameter and result types are all *L*-compatible. 18

- T is derived from an *L*-compatible type, 19
- {*AI12-0207-1*} T is an anonymous access type, and T is eligible for convention *L*, 19.1/5

  Reason: We say this so that the presence of an anonymous access component does not necessarily prevent a type from being eligible for convention *L*. We want the anonymous access type to take the convention from the enclosing type, but if we only said that, the definition would be circular (one can only portably apply the convention *L* to a record type R if the components of R already have convention *L*; but the anonymous components of R have to take the convention from R). We include the part of about T being eligible for convention *L* so that we don't force convention *L* on some type that is incompatible with it. 19.a/5

- The implementation permits T as an *L*-compatible type. 20

  Discussion: For example, an implementation might permit Integer as a C-compatible type, though the C type to which it corresponds might be different in different environments. 20.a

{*AI05-0229-1*} If the Convention aspect is specified for a type, then the type shall either be compatible with or eligible for the specified convention. 21/3

Ramification: {*AI05-0229-1*} If a type is derived from an *L*-compatible type, the derived type is by default *L*-compatible, but it is also permitted to specify the Convention aspect for the derived type. 21.a/3

{*AI05-0229-1*} It is permitted to specify the Convention aspect for an incomplete type, but in the complete declaration each component must be *L*-compatible. 21.b/3

{*AI05-0229-1*} If each component of a record type is *L*-compatible, then the record type itself is only *L*-compatible if it has a specified Convention. 21.c/3

{*AI12-0207-1*} If convention *L* is specified for a type T, for each component of T that has an anonymous access type, the convention of the anonymous access type is *L*. If convention *L* is specified for an object that has an anonymous access type, the convention of the anonymous access type is *L*. 21.1/5

Ramification: This applies to both anonymous access-to-object and anonymous access-to-subprogram types. 21.d/5

{*AI05-0229-1*} Notwithstanding any rule to the contrary, a declaration with a True Import aspect shall not have a completion. 22/3

Discussion: {*AI05-0229-1*} For declarations of deferred constants and subprograms, we explicitly mention that no completion is allowed when aspect Import is True. For other declarations that require completions, we ignore the possibility of the aspect Import being True. Nevertheless, if an implementation chooses to allow specifying aspect Import to be True for the declaration of a task, protected type, incomplete type, private type, etc., it may do so, and the normal completion is then not allowed for that declaration. 22.a/3

{*AI05-0229-1*} An entity with a True Import aspect (or Export aspect) is said to be *imported* (respectively, *exported*). An entity shall not be both imported and exported. 23/3

The declaration of an imported object shall not include an explicit initialization expression. [Default initializations are not performed.] 24

Proof: This follows from the “Notwithstanding ...” wording in the Dynamics Semantics paragraphs below. 24.a

25/3 {*AI05-0229-1*} The type of an imported or exported object shall be compatible with the specified Convention aspect, if any.

25.a **Ramification:** This implies, for example, that importing an Integer object might be illegal, whereas importing an object of type Interfaces.C.int would be permitted.

26/3 {*AI05-0229-1*} For an imported or exported subprogram, the result and parameter types shall each be compatible with the specified Convention aspect, if any.

27/3 {*AI05-0229-1*} The aspect_definition (if any) used to directly specify an Import, Export, External_Name, or Link_Name aspect shall be a static expression. The *string*_expression of a pragma Linker_Options shall be static. An External_Name or Link_Name aspect shall be specified only for an entity that is either imported or exported.

Static Semantics

Paragraphs 28 and 29 were deleted.

30/3 {*AI05-0229-1*} The Convention aspect represents the calling convention or representation convention of the entity. For an access-to-subprogram type, it represents the calling convention of designated subprograms. In addition:

31/3 - A True Import aspect indicates that the entity is defined externally (that is, outside the Ada program). This aspect is never inherited; if not directly specified, the Import aspect is False.

32/3 - A True Export aspect indicates that the entity is used externally. This aspect is never inherited; if not directly specified, the Export aspect is False.

33/3 - For an entity with a True Import or Export aspect, an external name, link name, or both may also be specified.

34 An *external name* is a string value for the name used by a foreign language program either for an entity that an Ada program imports, or for referring to an entity that an Ada program exports.

35 A *link name* is a string value for the name of an exported or imported entity, based on the conventions of the foreign language's compiler in interfacing with the system's linker tool.

36 The meaning of link names is implementation defined. If neither a link name nor the Address attribute of an imported or exported entity is specified, then a link name is chosen in an implementation-defined manner, based on the external name if one is specified.

36.a **Implementation defined:** The meaning of link names.

36.b **Ramification:** For example, an implementation might always prepend "_", and then pass it to the system linker.

36.c **Implementation defined:** The manner of choosing link names when neither the link name nor the address of an imported or exported entity is specified.

36.d **Ramification:** Normally, this will be the entity's defining name, or some simple transformation thereof.

37 Pragma Linker_Options has the effect of passing its string argument as a parameter to the system linker (if one exists), if the immediately enclosing compilation unit is included in the partition being linked. The interpretation of the string argument, and the way in which the string arguments from multiple Linker_Options pragmas are combined, is implementation defined.

37.a **Implementation defined:** The effect of pragma Linker_Options.

Dynamic Semantics

38/3 {*AI05-0229-1*} Notwithstanding what this document says elsewhere, the elaboration of a declaration with a True Import aspect does not create the entity. Such an elaboration has no other effect than to allow the defining name to denote the external entity.

Ramification: This implies that default initializations are skipped. (Explicit initializations are illegal.) For example, an imported access object is *not* initialized to **null**. 38.a

This paragraph was deleted.{*AI05-0229-1*} 38.b/3

Discussion: {*AI05-0229-1*} This “notwithstanding” wording is better than saying “unless aspect Import is True” on every definition of elaboration. It says we recognize the contradiction, and this rule takes precedence. 38.c/3

Erroneous Execution

{*AI95-00320-01*} {*AI05-0229-1*} {*AI12-0219-1*} It is the programmer's responsibility to ensure that the use of interfacing aspects does not violate Ada semantics; otherwise, program execution is erroneous. For example, passing an object with mode **in** to imported code that modifies it causes erroneous execution. Similarly, calling an imported subprogram that is not pure from a pure package causes erroneous execution. 38.1/5

Implementation Advice

{*AI05-0229-1*} If an implementation supports Export for a given language, then it should also allow the main subprogram to be written in that language. It should support some mechanism for invoking the elaboration of the Ada library units included in the system, and for invoking the finalization of the environment task. On typical systems, the recommended mechanism is to provide two subprograms whose link names are "adainit" and "adafinal". Adainit should contain the elaboration code for library units. Adafinal should contain the finalization code. These subprograms should have no effect the second and subsequent time they are called. 39/3

Implementation Advice: If Export is supported for a language, the main program should be able to be written in that language. Subprograms named "adainit" and "adafinal" should be provided for elaboration and finalization of the environment task. 39.a.1/3

Ramification: For example, if the main subprogram is written in C, it can call adainit before the first call to an Ada subprogram, and adafinal after the last. 39.a

{*AI05-0229-1*} {*AI05-0269-1*} Automatic elaboration of preelaborated packages should be provided when specifying the Export aspect as True is supported. 40/3

Implementation Advice: Automatic elaboration of preelaborated packages should be provided when specifying the Export aspect as True is supported. 40.a.1/3

{*AI05-0229-1*} {*AI12-0135-1*} {*AI12-0444-1*} For each supported convention *L* other than Intrinsic, an implementation should support specifying the Import and Export aspects for objects of *L*-compatible types and for subprograms, and the Convention aspect for *L*-eligible types and for subprograms, presuming the other language has corresponding features. Specifying the Convention aspect should be supported for enumeration types whose internal codes fall within the range 0 .. 2**15–1, but no recommendation is made for other scalar types. 41/5

Implementation Advice: For each supported convention *L* other than Intrinsic, specifying the aspects Import and Export should be supported for objects of *L*-compatible types and for subprograms, and aspect Convention should be supported for *L*-eligible types and for subprograms. 41.a.1/3

Reason: {*AI05-0229-1*} Specifying aspect Convention is not necessary for scalar types, since the language interface packages declare scalar types corresponding to those provided by the respective foreign languages. 41.a/3

Implementation Note: {*AI95-00114-01*} If an implementation supports interfacing to the C++ entities not supported by B.3, it should do so via the convention identifier C_Plus_Plus (in additional to any C++-implementation-specific ones). 41.b/2

Reason: {*AI95-00114-01*} The reason for giving the advice about C++ is to encourage uniformity among implementations, given that the name of the language is not syntactically legal as an identifier. 41.c/2

NOTE 1 {*AI05-0229-1*} {*AI12-0440-1*} Implementations can place restrictions on interfacing aspects; for example, requiring each exported entity to be declared at the library level. 42/5

Proof: Arbitrary restrictions are allowed by 13.1. 42.a

42.b **Ramification:** Such a restriction might be to disallow them altogether. Alternatively, the implementation might allow them only for certain kinds of entities, or only for certain conventions.

43/3 NOTE 2 {*AI05-0229-1*} The Convention aspect in combination with the Import aspect indicates the conventions for accessing external entities. It is possible that the actual entity is written in assembly language, but reflects the conventions of a particular language. For example, `with Convention => Ada` can be used to interface to an assembly language routine that obeys the Ada compiler's calling conventions.

44/5 NOTE 3 {*AI05-0229-1*} {*AI12-0440-1*} To obtain "call-back" to an Ada subprogram from a foreign language environment, the Convention aspect can be specified both for the access-to-subprogram type and the specific subprogram(s) to which 'Access is applied.

Paragraphs 45 and 46 were deleted.

47/5 NOTE 4 {*AI12-0449-1*} Machine code insertions can also be relevant for interfacing; see 13.8.

47.a/3 **Ramification:** {*AI05-0229-1*} The Intrinsic convention (see 6.3.1) implies that the entity is somehow "built in" to the implementation. Thus, it generally does not make sense for users to specify Intrinsic along with specifying that the entity is imported. The intention is that only implementations will specify Intrinsic for an imported entity. The language also defines certain subprograms to be Intrinsic.

47.b/3 **Discussion:** {*AI05-0229-1*} There are many imaginable interfacing aspects that don't make any sense. For example, setting the Convention of a protected procedure to Ada is probably wrong. Rather than enumerating all such cases, however, we leave it up to implementations to decide what is sensible.

48/3 NOTE 5 {*AI05-0229-1*} If both External_Name and Link_Name are specified for a given entity, then the External_Name is ignored.

49/2 *This paragraph was deleted.*{*AI95-00320-01*}

Examples

50/4 *{AI12-0080-1} Example of interfacing aspects:*

51/3
```
{AI05-0229-1} {AI05-0269-1} package Fortran_Library is
  function Sqrt (X : Float) return Float
    with Import => True, Convention => Fortran;
  type Matrix is array (Natural range <>, Natural range <>) of Float
    with Convention => Fortran;
  function Invert (M : Matrix) return Matrix
    with Import => True, Convention => Fortran;
end Fortran_Library;
```

Extensions to Ada 83

51.a Interfacing pragmas are new to Ada 95. Pragma Import replaces Ada 83's pragma Interface. Existing implementations can continue to support pragma Interface for upward compatibility.

Wording Changes from Ada 95

51.b/2 {*8652/0058*} {*AI95-00036-01*} **Corrigendum:** Clarified that pragmas Import and Export work like a subprogram call; parameters cannot be omitted unless named notation is used. (Reordering is still not permitted, however.)

51.c/2 {*AI95-00320-01*} Added wording to say all bets are off if foreign code doesn't follow the semantics promised by the Ada specifications.

Incompatibilities With Ada 2005

51.d/3 {*AI05-0002-1*} **Correction:** Access types that designate unconstrained arrays are no longer defined to be *L*-compatible. Such access-to-arrays require bounds information, which is likely to be incompatible with a foreign language. The change will allow (but not require) compilers to reject bad uses, which probably will not work anyway. Note that implementations can still support any type that it wants as *L*-compatible; such uses will not be portable, however. As such, there should be little existing code that will be impacted (compilers probably already rejected cases that could not be translated, whether or not the language allowed doing so formally).

Extensions to Ada 2005

51.e/3 {*AI05-0229-1*} Aspects Convention, Import, Export, Link_Name, and External_Name are new; pragmas Convention, Import, and Export are now obsolescent.

Incompatibilities With Ada 2012

{*AI12-0207-1*} **Correction:** The convention of anonymous access components is that of the enclosing type (in Ada 2012, it was Ada). Similarly, the convention of the anonymous access type of an object is that of the object (again, in Ada 2012 it was Ada). While this is formally incompatible, it should be more useful in portable code; it makes little sense to have a component of an Ada access type in a record with a C convention. For most implementations, this will have no real effect as convention Ada anonymous access types were allowed as C-compatible anyway. But such code was not portable, as this was not required in Ada 2012. 51.f/5

Extensions to Ada 2012

{*AI12-0135-1*} **Corrigendum:** Added a suggestion that convention be supported for enumeration types. This will make the use of enumeration types portable for implementations that support interfacing to a particular language. 51.g/4

Wording Changes from Ada 2012

{*AI12-0219-1*} **Correction:** Added some examples to the erroneous execution text; this is a very important rule as it means that Ada compilers can assume that provided interfacing declarations reflect the actual foreign code. 51.h/5

B.2 The Package Interfaces

Package Interfaces is the parent of several library packages that declare types and other entities useful for interfacing to foreign languages. It also contains some implementation-defined types that are useful across more than one language (in particular for interfacing to assembly language). 1

Implementation defined: The contents of the visible part of package Interfaces and its language-defined descendants. 1.a

Static Semantics

The library package Interfaces has the following skeletal declaration: 2

{*AI12-0414-1*} 3/5

```
package Interfaces
   with Pure is

   type Integer_n is range -2**(n-1) .. 2**(n-1) - 1;  --2's complement

   type Unsigned_n is mod 2**n;

   function Shift_Left  (Value : Unsigned_n; Amount : Natural)
      return Unsigned_n;
   function Shift_Right (Value : Unsigned_n; Amount : Natural)
      return Unsigned_n;
   function Shift_Right_Arithmetic (Value : Unsigned_n; Amount : Natural)
      return Unsigned_n;
   function Rotate_Left  (Value : Unsigned_n; Amount : Natural)
      return Unsigned_n;
   function Rotate_Right (Value : Unsigned_n; Amount : Natural)
      return Unsigned_n;
   ...
end Interfaces;
```

4 5 6

Implementation Requirements

An implementation shall provide the following declarations in the visible part of package Interfaces: 7

- Signed and modular integer types of *n* bits, if supported by the target architecture, for each *n* that is at least the size of a storage element and that is a factor of the word size. The names of these types are of the form Integer_*n* for the signed types, and Unsigned_*n* for the modular types; 8

  Ramification: For example, for a typical 32-bit machine the corresponding types might be Integer_8, Unsigned_8, Integer_16, Unsigned_16, Integer_32, and Unsigned_32. 8.a

  The wording above implies, for example, that Integer_16'Size = Unsigned_16'Size = 16. Unchecked conversions between same-Sized types will work as expected. 8.b

- For each such modular type in Interfaces, shifting and rotating subprograms as specified in the declaration of Interfaces above. These subprograms are Intrinsic. They operate on a bit-by-bit basis, using the binary representation of the value of the operands to yield a binary representation 9

for the result. The Amount parameter gives the number of bits by which to shift or rotate. For shifting, zero bits are shifted in, except in the case of Shift_Right_Arithmetic, where one bits are shifted in if Value is at least half the modulus.

9.a **Reason:** We considered making shifting and rotating be primitive operations of all modular types. However, it is a design principle of Ada that all predefined operations should be operators (not functions named by identifiers). (Note that an early version of Ada had "**abs**" as an identifier, but it was changed to a reserved word operator before standardization of Ada 83.) This is important because the implicit declarations would hide nonoverloadable declarations with the same name, whereas operators are always overloadable. Therefore, we would have had to make shift and rotate into reserved words, which would have been upward incompatible, or else invent new operator symbols, which seemed like too much mechanism.

9.b/5 **To be honest:** {*AI12-0264-1*} "Shifting" and "rotating" have the conventional meaning. Neither of these terms is usefully defined by the usual normative references of the Reference Manual, so we provide pseudo-code here to describe the intended semantics of the above wording (all operations in these examples are using modular semantics).

9.c/5
```
function Rotate_Left (Value : Unsigned_n; Amount : Natural)
   return Unsigned_n is
   Result : Unsigned_n := Value;
   Bit : Unsigned_n range 0 .. 1;
begin
   for Count in 1 .. Amount loop
      Bit := Result/2**(n-1); -- High-bit of Result
      Result := Result*2 + Bit;
   end loop;
   return Result;
end Rotate_Left;
```

9.d/5
```
function Rotate_Right (Value : Unsigned_n; Amount : Natural)
   return Unsigned_n is
   Result : Unsigned_n := Value;
   Bit : Unsigned_n range 0 .. 1;
begin
   for Count in 1 .. Amount loop
      Bit := Result mod 2; -- Low-bit of Result
      Result := Result/2 + (Bit * 2**(n-1));
   end loop;
   return Result;
end Rotate_Right;
```

9.e/5
```
function Shift_Left (Value : Unsigned_n; Amount : Natural)
   return Unsigned_n is
   Result : Unsigned_n := Value;
begin
   for Count in 1 .. Amount loop
      Result := Result * 2;
   end loop;
   return Result;
end Shift_Left;
```

9.f/5
```
function Shift_Right (Value : Unsigned_n; Amount : Natural)
   return Unsigned_n is
   Result : Unsigned_n := Value;
begin
   for Count in 1 .. Amount loop
      Result := Result / 2;
   end loop;
   return Result;
end Shift_Right;
```

9.g/5
```
function Shift_Right_Arithmetic (Value : Unsigned_n; Amount : Natural)
   return Unsigned_n is
   Result : Unsigned_n := Value;
   Neg : constant Boolean :=
      Result/2**(n-1) = 1; -- High-bit of Result
begin
   for Count in 1 .. Amount loop
      if Neg then
         Result := Result / 2 + 2**(n-1);
      else
         Result := Result / 2;
      end if;
   end loop;
   return Result;
end Shift_Right_Arithmetic;
```

{*AI12-0264-1*} These generally correspond to machine instructions, although there may not be an exact match in terms of boundary conditions, as Ada requires the correct result to be produced for all values of Amount. 9.h/5

- Floating point types corresponding to each floating point format fully supported by the hardware. 10

Implementation Note: The names for these floating point types are not specified. However, if IEEE arithmetic is supported, then the names should be IEEE_Float_32 and IEEE_Float_64 for single and double precision, respectively. 10.a

Implementation Permissions

An implementation may provide implementation-defined library units that are children of Interfaces, and may add declarations to the visible part of Interfaces in addition to the ones defined above. 11

Implementation defined: Implementation-defined children of package Interfaces. 11.a/2

{*AI95-00204-01*} {*AI05-0229-1*} A child package of package Interfaces with the name of a convention may be provided independently of whether the convention is supported by the Convention aspect and vice versa. Such a child package should contain any declarations that would be useful for interfacing to the language (implementation) represented by the convention. Any declarations useful for interfacing to any language on the given hardware architecture should be provided directly in Interfaces. 11.1/3

Ramification: For example, package Interfaces.XYZ_Pascal might contain declarations of types that match the data types provided by the XYZ implementation of Pascal, so that it will be more convenient to pass parameters to a subprogram whose convention is XYZ_Pascal. 11.b/2

Implementation Advice

This paragraph was deleted.{*AI95-00204-01*} 12/2

This paragraph was deleted. 12.a/2

{*AI05-0299-1*} An implementation supporting an interface to C, COBOL, or Fortran should provide the corresponding package or packages described in the following subclauses. 13/3

Implementation Advice: If an interface to C, COBOL, or Fortran is provided, the corresponding package or packages described in Annex B, “Interface to Other Languages” should also be provided. 13.a.1/2

Implementation Note: The intention is that an implementation might support several implementations of the foreign language: Interfaces.This_Fortran and Interfaces.That_Fortran might both exist. The “default” implementation, overridable by the user, should be declared as a renaming: 13.a

```
package Interfaces.Fortran renames Interfaces.This_Fortran;
```
13.b

Wording Changes from Ada 95

{*AI95-00204-01*} Clarified that interfacing to foreign languages is optional and has the same restrictions as a Specialized Needs Annex. 13.c/2

Wording Changes from Ada 2005

{*AI05-0262-1*} Move the restrictions on implementations of optional features to the start of this Annex. 13.d/3

B.3 Interfacing with C and C++

{*8652/0059*} {*AI95-00131-01*} {*AI95-00376-01*} {*AI05-0229-1*} {*AI12-0028-1*} The facilities relevant to interfacing with the C language and the corresponding subset of the C++ language are the package Interfaces.C and its children, and support for specifying the Convention aspect with *convention*_identifiers C, C_Pass_By_Copy, and any of the C_Variadic_*n* conventions described below. 1/4

{*AI95-00376-01*} {*AI95-0262-1*} {*AI95-0299-1*} The package Interfaces.C contains the basic types, constants, and subprograms that allow an Ada program to pass scalars and strings to C and C++ functions. When this subclause mentions a C entity, the reference also applies to the corresponding entity in C++. 2/3

Static Semantics

3 The library package Interfaces.C has the following declaration:

4/5
```
{AI12-0414-1} package Interfaces.C
   with Pure is

   -- Declarations based on C's <limits.h>

   CHAR_BIT  : constant := implementation-defined;   -- typically 8
   SCHAR_MIN : constant := implementation-defined;   -- typically –128
   SCHAR_MAX : constant := implementation-defined;   -- typically 127
   UCHAR_MAX : constant := implementation-defined;   -- typically 255

   -- Signed and Unsigned Integers
   type int   is range implementation-defined;
   type short is range implementation-defined;
   type long  is range implementation-defined;

   type signed_char is range SCHAR_MIN .. SCHAR_MAX;
   for signed_char'Size use CHAR_BIT;

   type unsigned       is mod implementation-defined;
   type unsigned_short is mod implementation-defined;
   type unsigned_long  is mod implementation-defined;

   type unsigned_char is mod (UCHAR_MAX+1);
   for unsigned_char'Size use CHAR_BIT;

   subtype plain_char is implementation-defined;

   type ptrdiff_t is range implementation-defined;

   type size_t is mod implementation-defined;

{AI12-0411-1}     -- Boolean Type
   type C_bool is new Boolean;

   -- Floating Point

   type C_float     is digits implementation-defined;

   type double      is digits implementation-defined;

   type long_double is digits implementation-defined;

   -- Characters and Strings

   type char is <implementation-defined character type>;

{8652/0060} {AI95-00037-01}    nul : constant char := implementation-defined;

   function To_C   (Item : in Character) return char;

   function To_Ada (Item : in char) return Character;

{AI05-0229-1} {AI05-0269-1}    type char_array is array (size_t range <>) of
aliased char
      with Pack;

41.a.1/2 **Implementation defined:** The definitions of certain types and constants in Interfaces.C.

42 Each of the types declared in Interfaces.C is C-compatible.

43/5 {*AI95-00285-01*} {*AI12-0411-1*} The types int, short, long, unsigned, ptrdiff_t, size_t, double, char, wchar_t, char16_t, and char32_t correspond respectively to the C types having the same names. The types signed_char, unsigned_short, unsigned_long, unsigned_char, C_bool, C_float, and long_double correspond respectively to the C types signed char, unsigned short, unsigned long, unsigned char, bool, float, and long double.

43.a/2 **Discussion:** The C types wchar_t and char16_t seem to be the same. However, wchar_t has an implementation-defined size, whereas char16_t is guaranteed to be an unsigned type of at least 16 bits. Also, char16_t and char32_t are encouraged to have UTF-16 and UTF-32 representations; that means that they are not directly the same as the Ada types, which most likely don't use any UTF encoding.

44 The type of the subtype plain_char is either signed_char or unsigned_char, depending on the C implementation.

45
```
function To_C   (Item : in Character) return char;
function To_Ada (Item : in char     ) return Character;
```

46 The functions To_C and To_Ada map between the Ada type Character and the C type char.

46.a.1/1 **Implementation Note:** {*8652/0114*} {*AI95-00038-01*} The To_C and To_Ada functions map between corresponding characters, not necessarily between characters with the same internal representation. Corresponding characters are characters defined by the same enumeration literal, if such exist; otherwise, the correspondence is unspecified.

46.a.2/1 The following definition is equivalent to the above summary:

46.a.3/1 `To_C (Latin_1_Char) = char'Value(Character'Image(Latin_1_Char))`
provided that char'Value does not raise an exception; otherwise the result is unspecified.

46.a.4/1 `To_Ada (Native_C_Char) = Character'Value(char'Image(Native_C_Char))`
provided that Character'Value does not raise an exception; otherwise the result is unspecified.

47
```
function Is_Nul_Terminated (Item : in char_array) return Boolean;
```

48 The result of Is_Nul_Terminated is True if Item contains nul, and is False otherwise.

49
```
function To_C   (Item : in String;     Append_Nul : in Boolean := True)
   return char_array;

function To_Ada (Item : in char_array; Trim_Nul   : in Boolean := True)
   return String;
```

50/2 {*AI95-00258-01*} The result of To_C is a char_array value of length Item'Length (if Append_Nul is False) or Item'Length+1 (if Append_Nul is True). The lower bound is 0. For each component Item(I), the corresponding component in the result is To_C applied to Item(I). The value nul is

appended if Append_Nul is True. If Append_Nul is False and Item'Length is 0, then To_C propagates Constraint_Error.

The result of To_Ada is a String whose length is Item'Length (if Trim_Nul is False) or the length of the slice of Item preceding the first nul (if Trim_Nul is True). The lower bound of the result is 1. If Trim_Nul is False, then for each component Item(I) the corresponding component in the result is To_Ada applied to Item(I). If Trim_Nul is True, then for each component Item(I) before the first nul the corresponding component in the result is To_Ada applied to Item(I). The function propagates Terminator_Error if Trim_Nul is True and Item does not contain nul. 51

```
procedure To_C (Item       : in  String;                                    52
                Target     : out char_array;
                Count      : out size_t;
                Append_Nul : in  Boolean := True);

procedure To_Ada (Item     : in  char_array;
                  Target   : out String;
                  Count    : out Natural;
                  Trim_Nul : in  Boolean := True);
```

For procedure To_C, each element of Item is converted (via the To_C function) to a char, which is assigned to the corresponding element of Target. If Append_Nul is True, nul is then assigned to the next element of Target. In either case, Count is set to the number of Target elements assigned. If Target is not long enough, Constraint_Error is propagated. 53

For procedure To_Ada, each element of Item (if Trim_Nul is False) or each element of Item preceding the first nul (if Trim_Nul is True) is converted (via the To_Ada function) to a Character, which is assigned to the corresponding element of Target. Count is set to the number of Target elements assigned. If Target is not long enough, Constraint_Error is propagated. If Trim_Nul is True and Item does not contain nul, then Terminator_Error is propagated. 54

```
function Is_Nul_Terminated (Item : in wchar_array) return Boolean;          55
```

The result of Is_Nul_Terminated is True if Item contains wide_nul, and is False otherwise. 56

```
function To_C   (Item : in Wide_Character) return wchar_t;                  57
function To_Ada (Item : in wchar_t       ) return Wide_Character;
```

To_C and To_Ada provide the mappings between the Ada and C wide character types. 58

```
function To_C   (Item       : in Wide_String;                               59
                 Append_Nul : in Boolean := True)
   return wchar_array;

function To_Ada (Item     : in wchar_array;
                 Trim_Nul : in Boolean := True)
   return Wide_String;

procedure To_C (Item       : in  Wide_String;
                Target     : out wchar_array;
                Count      : out size_t;
                Append_Nul : in  Boolean := True);

procedure To_Ada (Item     : in  wchar_array;
                  Target   : out Wide_String;
                  Count    : out Natural;
                  Trim_Nul : in  Boolean := True);
```

The To_C and To_Ada subprograms that convert between Wide_String and wchar_array have analogous effects to the To_C and To_Ada subprograms that convert between String and char_array, except that wide_nul is used instead of nul. 60

60.1/2
```
function Is_Nul_Terminated (Item : in char16_array) return Boolean;
```

60.2/2 {*AI95-00285-01*} The result of Is_Nul_Terminated is True if Item contains char16_nul, and is False otherwise.

60.3/2
```
function To_C (Item : in Wide_Character) return char16_t;
function To_Ada (Item : in char16_t ) return Wide_Character;
```

60.4/2 {*AI95-00285-01*} To_C and To_Ada provide mappings between the Ada and C 16-bit character types.

60.5/2
```
function To_C (Item       : in Wide_String;
               Append_Nul : in Boolean := True)
   return char16_array;

function To_Ada (Item     : in char16_array;
                 Trim_Nul : in Boolean := True)
   return Wide_String;

procedure To_C (Item       : in  Wide_String;
                Target     : out char16_array;
                Count      : out size_t;
                Append_Nul : in  Boolean := True);

procedure To_Ada (Item     : in  char16_array;
                  Target   : out Wide_String;
                  Count    : out Natural;
                  Trim_Nul : in  Boolean := True);
```

60.6/2 {*AI95-00285-01*} The To_C and To_Ada subprograms that convert between Wide_String and char16_array have analogous effects to the To_C and To_Ada subprograms that convert between String and char_array, except that char16_nul is used instead of nul.

60.7/2
```
function Is_Nul_Terminated (Item : in char32_array) return Boolean;
```

60.8/5 {*AI95-00285-01*} {*AI12-0437-1*} The result of Is_Nul_Terminated is True if Item contains char32_nul, and is False otherwise.

60.9/2
```
function To_C (Item : in Wide_Wide_Character) return char32_t;
function To_Ada (Item : in char32_t ) return Wide_Wide_Character;
```

60.10/2 {*AI95-00285-01*} To_C and To_Ada provide mappings between the Ada and C 32-bit character types.

60.11/2
```
function To_C (Item       : in Wide_Wide_String;
               Append_Nul : in Boolean := True)
   return char32_array;

function To_Ada (Item     : in char32_array;
                 Trim_Nul : in Boolean := True)
   return Wide_Wide_String;

procedure To_C (Item       : in  Wide_Wide_String;
                Target     : out char32_array;
                Count      : out size_t;
                Append_Nul : in  Boolean := True);

procedure To_Ada (Item     : in  char32_array;
                  Target   : out Wide_Wide_String;
                  Count    : out Natural;
                  Trim_Nul : in  Boolean := True);
```

60.12/2 {*AI95-00285-01*} The To_C and To_Ada subprograms that convert between Wide_Wide_String and char32_array have analogous effects to the To_C and To_Ada subprograms that convert between String and char_array, except that char32_nul is used instead of nul.

Discussion: The Interfaces.C package provides an implementation-defined character type, char, designed to model the C run-time character set, and mappings between the types char and Character. 60.a

One application of the C interface package is to compose a C string and pass it to a C function. One way to do this is for the programmer to declare an object that will hold the C array, and then pass this array to the C function. This is realized via the type char_array: 60.b

```
type char_array is array (size_t range <>) of Char;
```
60.c

The programmer can declare an Ada String, convert it to a char_array, and pass the char_array as actual parameter to the C function that is expecting a char *. 60.d

An alternative approach is for the programmer to obtain a C char pointer from an Ada String (or from a char_array) by invoking an allocation function. The package Interfaces.C.Strings (see below) supplies the needed facilities, including a private type chars_ptr that corresponds to C's char *, and two allocation functions. To avoid storage leakage, a Free procedure releases the storage that was allocated by one of these allocate functions. 60.e

It is typical for a C function that deals with strings to adopt the convention that the string is delimited by a nul char. The C interface packages support this convention. A constant nul of type Char is declared, and the function Value(Chars_Ptr) in Interfaces.C.Strings returns a char_array up to and including the first nul in the array that the chars_ptr points to. The Allocate_Chars function allocates an array that is nul terminated. 60.f

Some C functions that deal with strings take an explicit length as a parameter, thus allowing strings to be passed that contain nul as a data element. Other C functions take an explicit length that is an upper bound: the prefix of the string up to the char before nul, or the prefix of the given length, is used by the function, whichever is shorter. The C Interface packages support calling such functions. 60.g

{*8652/0059*} {*AI95-00131-01*} {*AI05-0229-1*} The Convention aspect with *convention*_identifier C_Pass_By_Copy shall only be specified for a type. 60.13/3

{*8652/0059*} {*AI95-00131-01*} {*AI95-00216-01*} The eligibility rules in B.1 do not apply to convention C_Pass_By_Copy. Instead, a type T is eligible for convention C_Pass_By_Copy if T is an unchecked union type or if T is a record type that has no discriminants and that only has components with statically constrained subtypes, and each component is C-compatible. 60.14/2

{*8652/0059*} {*AI95-00131-01*} {*AI05-0264-1*} If a type is C_Pass_By_Copy-compatible, then it is also C-compatible. 60.15/3

{*AI12-0028-1*} The identifiers C_Variadic_0, C_Variadic_1, C_Variadic_2, and so on are *convention*_identifiers. These conventions are said to be *C_Variadic*. The convention C_Variadic_*n* is the calling convention for a variadic C function taking *n* fixed parameters and then a variable number of additional parameters. The C_Variadic_*n* convention shall only be specified as the convention aspect for a subprogram, or for an access-to-subprogram type, having at least *n* parameters. A type is compatible with a C_Variadic convention if and only if the type is C-compatible. 60.16/4

To be honest: It is implementation defined what the largest *n* in C_Variadic_*n* is supported. We don't say this because it complicates the wording and it is true for almost any *convention*_identifier (only Ada is required to be supported by the language, all others need to be documented in order for programmers to know that they are available). 60.h/4

Implementation Requirements

{*8652/0059*} {*AI95-00131-01*} {*AI05-0229-1*} An implementation shall support specifying aspect Convention with a C *convention*_identifier for a C-eligible type (see B.1). An implementation shall support specifying aspect Convention with a C_Pass_By_Copy *convention*_identifier for a C_Pass_By_Copy-eligible type. 61/3

Implementation Permissions

An implementation may provide additional declarations in the C interface packages. 62

{*AI05-0002-1*} {*AI05-0229-1*} {*AI12-0444-1*} An implementation is not required to support specifying the Convention aspect with *convention*_identifier C in the following cases: 62.1/5

- {*AI05-0248-1*} for a subprogram that has a parameter of an unconstrained array subtype, unless the Import aspect has the value True for the subprogram; 62.2/3

62.3/3 • for a function with an unconstrained array result subtype;

62.4/3 • for an object whose nominal subtype is an unconstrained array subtype.

62.a/3 **Implementation Note:** {*AI05-0002-1*} These rules ensure that an implementation never needs to create bounds for an unconstrained array that originates in C (and thus does not have bounds). An implementation can do so if it wishes, of course. Note that these permissions do not extend to passing an unconstrained array as a parameter to a C function; in this case, the bounds can simply be dropped and thus support is required.

Implementation Advice

62.5/3 {*8652/0060*} {*AI95-00037-01*} {*AI95-00285-01*} The constants nul, wide_nul, char16_nul, and char32_nul should have a representation of zero.

62.b/2 **Implementation Advice:** The constants nul, wide_nul, char16_nul, and char32_nul in package Interfaces.C should have a representation of zero.

63 An implementation should support the following interface correspondences between Ada and C.

64 • An Ada procedure corresponds to a void-returning C function.

64.a **Discussion:** The programmer can also choose an Ada procedure when the C function returns an int that is to be discarded.

65 • An Ada function corresponds to a non-void C function.

65.1/4 • {*AI12-0135-1*} An Ada enumeration type corresponds to a C enumeration type with corresponding enumeration literals having the same internal codes, provided the internal codes fall within the range of the C int type.

66 • An Ada **in** scalar parameter is passed as a scalar argument to a C function.

67 • An Ada **in** parameter of an access-to-object type with designated type T is passed as a t* argument to a C function, where t is the C type corresponding to the Ada type T.

68 • An Ada **access** T parameter, or an Ada **out** or **in out** parameter of an elementary type T, is passed as a t* argument to a C function, where t is the C type corresponding to the Ada type T. In the case of an elementary **out** or **in out** parameter, a pointer to a temporary copy is used to preserve by-copy semantics.

68.1/2 • {*8652/0059*} {*AI95-00131-01*} {*AI95-00343-01*} An Ada parameter of a (record) type T of convention C_Pass_By_Copy, of mode **in**, is passed as a t argument to a C function, where t is the C struct corresponding to the Ada type T.

69/5 • {*8652/0059*} {*AI95-00131-01*} {*AI95-00343-01*} {*AI12-0219-1*} An Ada parameter of a record type T, other than an **in** parameter of a type of convention C_Pass_By_Copy, is passed as a t* argument to a C function, with the const modifier if the Ada mode is **in**, where t is the C struct corresponding to the Ada type T.

70/5 • {*AI12-0219-1*} An Ada parameter of an array type with component type T is passed as a t* argument to a C function, with the const modifier if the Ada mode is **in**, where t is the C type corresponding to the Ada type T.

71 • An Ada parameter of an access-to-subprogram type is passed as a pointer to a C function whose prototype corresponds to the designated subprogram's specification.

71.1/3 • {*AI05-0002-1*} An Ada parameter of a private type is passed as specified for the full view of the type.

71.2/3 • {*AI05-0002-1*} The rules of correspondence given above for parameters of mode **in** also apply to the return object of a function.

71.3/5 {*AI95-00337-01*} {*AI05-0002-1*} {*AI12-0184-1*} An implementation should provide unsigned_long_long and long_long as 64-bit modular and signed integer types (respectively) in package Interfaces.C if the C implementation supports unsigned long long and long long as 64-bit types.

Implementation Advice: If C interfacing is supported, the interface correspondences between Ada and C should be supported. 71.a/2

Implementation Advice: If the C implementation supports unsigned long long and long long, unsigned_long_long and long_long should be supported. 71.a.1/5

NOTE 1 Values of type char_array are not implicitly terminated with nul. If a char_array is to be passed as a parameter to an imported C function requiring nul termination, it is the programmer's responsibility to obtain this effect. 72

NOTE 2 To obtain the effect of C's sizeof(item_type), where Item_Type is the corresponding Ada type, evaluate the expression: size_t(Item_Type'Size/CHAR_BIT). 73

This paragraph was deleted.{*AI95-00216-01*} 74/2

NOTE 3 {*AI12-0028-1*} A variadic C function can correspond to several Ada subprograms, taking various specific numbers and types of parameters. 75/4

Examples

Example of using the Interfaces.C package: 76

```
{AI12-0312-1} --Calling the C Library Functions strcpy and printf                    77/5
with Interfaces.C;
procedure Test is
   package C renames Interfaces.C;
   use type C.char_array;
   -- Call <string.h>strcpy:
   -- C definition of strcpy:  char *strcpy(char *s1, const char *s2);
   --    This function copies the string pointed to by s2 (including the terminating null character)
   --    into the array pointed to by s1. If copying takes place between objects that overlap,
   --    the behavior is undefined. The strcpy function returns the value of s1.

{AI05-0229-1}      -- Note: since the C function's return value is of no interest, the Ada interface is a procedure   78/3
   procedure Strcpy (Target : out C.char_array;
                     Source : in  C.char_array)
      with Import => True, Convention => C, External_Name => "strcpy";

{AI05-0229-1} {AI12-0312-1}      -- Call <sdtio.h>printf:                          79/5
   -- C definition of printf:  int printf ( const char * format, ... );
   --    This function writes the C string pointed by format to the standard output (stdout).
   --    If format includes format specifiers (subsequences beginning with %), the additional
   --    arguments following format are formatted and inserted in the resulting string
   --    replacing their respective specifiers. If the number of arguments does not match
   --    the number of format specifiers, or if the types of the arguments do not match
   --    the corresponding format specifier, the behaviour is undefined. On success, the
   --    printf function returns the total number of characters written to the standard output.
   --    If a writing error occurs, a negative number is returned.

{AI12-0312-1}      -- Note: since the C function's return value is of no interest, the Ada interface is a procedure   79.1/5
   procedure Printf (Format : in C.char_array;
                     Param1 : in C.char_array;
                     Param2 : in C.int)
      with Import => True, Convention => C_Variadic_1, External_Name => "printf";

   Chars1 :  C.char_array(1..20);                                                    80
   Chars2 :  C.char_array(1..20);

begin                                                                                81
   Chars2(1..6) := "qwert" & C.nul;

   Strcpy(Chars1, Chars2);                                                           82

   -- Now Chars1(1..6) = "qwert" & C.Nul                                            83

{AI12-0312-1}     Printf("The String=%s, Length=%d", Chars1, Chars1'Length);       83.1/5

end Test;                                                                            84
```

Incompatibilities With Ada 95

{*AI95-00285-01*} {*AI05-0005-1*} Types char16_t and char32_t and their related types and operations are added to Interfaces.C. If Interfaces.C is referenced in a use_clause, and an entity *E* with the same defining_identifier as a new entity in Interfaces.C is defined in a package that is also referenced in a use_clause, the entity *E* may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur. 84.a/3

Extensions to Ada 95

84.b/2 {*8652/0059*} {*AI95-00131-01*} **Corrigendum:** Convention C_Pass_By_Copy is new.

Wording Changes from Ada 95

84.c/2 {*8652/0060*} {*AI95-00037-01*} **Corrigendum:** Clarified the intent for Nul and Wide_Nul.

84.d/2 {*AI95-00216-01*} Specified that an unchecked union type (see B.3.3) is eligible for convention C_Pass_By_Copy.

84.e/2 {*AI95-00258-01*} Specified what happens if the To_C function tries to return a null string.

84.f/2 {*AI95-00337-01*} Clarified that the interface correspondences also apply to private types whose full types have the specified characteristics.

84.g/2 {*AI95-00343-01*} Clarified that a type must have convention C_Pass_By_Copy in order to be passed by copy (not just a type that could have that convention).

84.h/2 {*AI95-00376-01*} Added wording to make it clear that these facilities can also be used with C++.

Incompatibilities With Ada 2005

84.i/3 {*AI05-0002-1*} **Correction:** Added a definition of correspondences for function results. Also added wording to make it clear that we do not expect the implementation to conjure bounds for unconstrained arrays out of thin air. These changes allow (but don't require) compilers to reject unreasonable uses of array types. Such uses probably didn't work anyway (and probably were rejected, no matter what the language definition said), so little existing code should be impacted.

Incompatibilities With Ada 2012

84.j/5 {*AI12-0411-1*} Added type C_bool and (implicitly) the enumeration literals True and False to the Interfaces.C package. Therefore, a use clause conflict is possible; see the introduction of Annex A for more on this topic.

Extensions to Ada 2012

84.k/4 {*AI12-0028-1*} **Corrigendum:** The *convention*_identifiers C_Variadic_0, C_Variadic_1, and so on are new. These are classified as a correction as any implementation can add such identifiers and it is important that special conventions be available for variadic functions as typical x64 conventions are different for normal and variadic C functions.

84.l/4 {*AI12-0135-1*} **Corrigendum:** Defined the correspondence between an Ada enumeration type and a C enumeration type; implementations should support convention C for enumeration types.

Wording Changes from Ada 2012

84.m/5 {*AI12-0184-1*} Added Implementation Advice that types be defined in Interfaces.C corresponding to long long and unsigned long long.

84.n/5 {*AI12-0219-1*} **Correction:** Added advice that const t* map to Ada **in** parameters and vice versa.

84.o/5 {*AI12-0411-1*} Added advice about mapping type Boolean.

B.3.1 The Package Interfaces.C.Strings

1/3 {*AI05-0229-1*} The package Interfaces.C.Strings declares types and subprograms allowing an Ada program to allocate, reference, update, and free C-style strings. In particular, the private type chars_ptr corresponds to a common use of “char *” in C programs, and an object of this type can be passed to a subprogram to which **with** `Import => True, Convention => C` has been specified, and for which “char *” is the type of the argument of the C function.

Static Semantics

2 The library package Interfaces.C.Strings has the following declaration:

```
3/5     {AI12-0241-1} {AI12-0302-1} package Interfaces.C.Strings
           with Preelaborate, Nonblocking, Global => in out synchronized is

4          type char_array_access is access all char_array;

5/5     {AI95-00161-01} {AI12-0399-1}    type chars_ptr is private
              with Preelaborable_Initialization;
```

```
{AI95-00276-01}    type chars_ptr_array is array (size_t range <>) of aliased chars_ptr;
```
6/2

```
   Null_Ptr : constant chars_ptr;
```
7

```
   function To_Chars_Ptr (Item      : in char_array_access;
                          Nul_Check : in Boolean := False)
      return chars_ptr;
```
8

```
   function New_Char_Array (Chars   : in char_array) return chars_ptr;
```
9

```
   function New_String (Str : in String) return chars_ptr;
```
10

```
   procedure Free (Item : in out chars_ptr);
```
11

```
   Dereference_Error : exception;
```
12

```
   function Value (Item : in chars_ptr) return char_array;
```
13

```
   function Value (Item : in chars_ptr; Length : in size_t)
      return char_array;
```
14

```
   function Value (Item : in chars_ptr) return String;
```
15

```
   function Value (Item : in chars_ptr; Length : in size_t)
      return String;
```
16

```
   function Strlen (Item : in chars_ptr) return size_t;
```
17

```
   procedure Update (Item   : in chars_ptr;
                     Offset : in size_t;
                     Chars  : in char_array;
                     Check  : in Boolean := True);
```
18

```
   procedure Update (Item   : in chars_ptr;
                     Offset : in size_t;
                     Str    : in String;
                     Check  : in Boolean := True);
```
19

```
   Update_Error : exception;
```
20

```
private
```
21

```
   ... -- not specified by the language
end Interfaces.C.Strings;
```

Discussion: The string manipulation types and subprograms appear in a child of Interfaces.C versus being there directly, since it is useful to have Interfaces.C specified as pragma Pure. 21.a

Differently named functions New_String and New_Char_Array are declared, since if there were a single overloaded function a call with a string literal as actual parameter would be ambiguous. 21.b

The type chars_ptr is C-compatible and corresponds to the use of C's “char *” for a pointer to the first char in a char array terminated by nul. When an object of type chars_ptr is declared, its value is by default set to Null_Ptr, unless the object is imported (see B.1). 22

Discussion: The type char_array_access is not necessarily C-compatible, since an object of this type may carry “dope” information. The programmer should convert from char_array_access to chars_ptr for objects imported from, exported to, or passed to C. 22.a

```
function To_Chars_Ptr (Item      : in char_array_access;
                       Nul_Check : in Boolean := False)
   return chars_ptr;
```
23

{8652/0061} *{AI95-00140-01}* *{AI05-0264-1}* If Item is **null**, then To_Chars_Ptr returns Null_Ptr. If Item is not **null**, Nul_Check is True, and Item.**all** does not contain nul, then the function propagates Terminator_Error; otherwise, To_Chars_Ptr performs a pointer conversion with no allocation of memory. 24/3

```
function New_Char_Array (Chars   : in char_array) return chars_ptr;
```
25

This function returns a pointer to an allocated object initialized to Chars(Chars'First .. Index) & nul, where 26

- Index = Chars'Last if Chars does not contain nul, or 27

- Index is the smallest size_t value I such that Chars(I+1) = nul.

Storage_Error is propagated if the allocation fails.

```
function New_String (Str : in String) return chars_ptr;
```

This function is equivalent to New_Char_Array(To_C(Str)).

```
procedure Free (Item : in out chars_ptr);
```

If Item is Null_Ptr, then Free has no effect. Otherwise, Free releases the storage occupied by Value(Item), and resets Item to Null_Ptr.

```
function Value (Item : in chars_ptr) return char_array;
```

{*AI05-0264-1*} If Item = Null_Ptr, then Value propagates Dereference_Error. Otherwise, Value returns the prefix of the array of chars pointed to by Item, up to and including the first nul. The lower bound of the result is 0. If Item does not point to a nul-terminated string, then execution of Value is erroneous.

```
function Value (Item : in chars_ptr; Length : in size_t)
   return char_array;
```

{*8652/0062*} {*AI95-00139-01*} {*AI05-0264-1*} If Item = Null_Ptr, then Value propagates Dereference_Error. Otherwise, Value returns the shorter of two arrays, either the first Length chars pointed to by Item, or Value(Item). The lower bound of the result is 0. If Length is 0, then Value propagates Constraint_Error.

Ramification: Value(New_Char_Array(Chars)) = Chars if Chars does not contain nul; else Value(New_Char_Array(Chars)) is the prefix of Chars up to and including the first nul.

```
function Value (Item : in chars_ptr) return String;
```

Equivalent to To_Ada(Value(Item), Trim_Nul=>True).

```
function Value (Item : in chars_ptr; Length : in size_t)
   return String;
```

{*8652/0063*} {*AI95-00177-01*} Equivalent to To_Ada(Value(Item, Length) & nul, Trim_Nul=>True).

```
function Strlen (Item : in chars_ptr) return size_t;
```

Returns *Val*'Length–1 where *Val* = Value(Item); propagates Dereference_Error if Item = Null_Ptr.

Ramification: Strlen returns the number of chars in the array pointed to by Item, up to and including the char immediately before the first nul.

Strlen has the same possibility for erroneous execution as Value, in cases where the string has not been nul-terminated.

Strlen has the effect of C's strlen function.

```
procedure Update (Item   : in chars_ptr;
                  Offset : in size_t;
                  Chars  : in char_array;
                  Check  : Boolean := True);
```

{*8652/0064*} {*AI95-00039-01*} If Item = Null_Ptr, then Update propagates Dereference_Error. Otherwise, this procedure updates the value pointed to by Item, starting at position Offset, using Chars as the data to be copied into the array. Overwriting the nul terminator, and skipping with the Offset past the nul terminator, are both prevented if Check is True, as follows:

- Let N = Strlen(Item). If Check is True, then:
  - If Offset+Chars'Length>N, propagate Update_Error.

- Otherwise, overwrite the data in the array pointed to by Item, starting at the char at position Offset, with the data in Chars. 47

- If Check is False, then processing is as above, but with no check that Offset+Chars'Length>N. 48

Ramification: If Chars contains nul, Update's effect may be to “shorten” the pointed-to char array. 48.a

```
procedure Update (Item   : in chars_ptr;                                    49
                  Offset : in size_t;
                  Str    : in String;
                  Check  : in Boolean := True);
```

{*AI95-00242-01*} Equivalent to Update(Item, Offset, To_C(Str, Append_Nul => False), Check). 50/2

Discussion: {*AI95-00242-01*} To truncate the Item to the length of Str, use Update(Item, Offset, To_C(Str), Check) instead of Update(Item, Offset, Str, Check). Note that when truncating Item, Item must be longer than Str. 50.a/2

Erroneous Execution

Execution of any of the following is erroneous if the Item parameter is not null_ptr and Item does not point to a nul-terminated array of chars. 51

- a Value function not taking a Length parameter, 52
- the Free procedure, 53
- the Strlen function. 54

Execution of Free(X) is also erroneous if the chars_ptr X was not returned by New_Char_Array or New_String. 55

Reading or updating a freed char_array is erroneous. 56

Execution of Update is erroneous if Check is False and a call with Check equal to True would have propagated Update_Error. 57

NOTE {*AI12-0440-1*} New_Char_Array and New_String can be implemented either through the allocation function from the C environment (“malloc”) or through Ada dynamic memory allocation (“new”). The key points are 58/5

- {*AI12-0440-1*} the returned value (a chars_ptr) is represented as a C “char *” so that it can be passed to C functions; 59/5
- {*AI12-0442-1*} the allocated object can be freed by the programmer via a call of Free, rather than by calling a C function. 60/5

Inconsistencies With Ada 95

{*AI95-00242-01*} **Amendment Correction:** Update for a String parameter is now defined to not add a nul character. It did add a nul in Ada 95. This means that programs that used this behavior of Update to truncate a string will no longer work (the string will not be truncated). This change makes Update for a string consistent with Update for a char_array (no implicit nul is added to the end of a char_array). 60.a/2

Extensions to Ada 95

{*AI95-00161-01*} **Amendment Correction:** Added pragma Preelaborable_Initialization to type chars_ptr, so that it can be used in preelaborated units. 60.b/2

{*AI95-00276-01*} **Amendment Correction:** The components of chars_ptr_array are aliased so that it can be used to instantiate Interfaces.C.Pointers (that is its intended purpose, which is otherwise mysterious as it has no operations). 60.c/2

Wording Changes from Ada 95

{*8652/0061*} {*AI95-00140-01*} **Corrigendum:** Fixed the missing semantics of To_Char_Ptr when Nul_Check is False. 60.d/2

{*8652/0062*} {*AI95-00139-01*} **Corrigendum:** Fixed the missing semantics of Value when the Length is 0. 60.e/2

{*8652/0063*} {*AI95-00177-01*} **Corrigendum:** Corrected the definition of Value to avoid raising Terminator_Error. 60.f/2

{*8652/0064*} {*AI95-00039-01*} **Corrigendum:** Fixed the missing semantics of Update when Item is Null_Ptr. 60.g/2

B.3.2 The Generic Package Interfaces.C.Pointers

1 The generic package Interfaces.C.Pointers allows the Ada programmer to perform C-style operations on pointers. It includes an access type Pointer, Value functions that dereference a Pointer and deliver the designated array, several pointer arithmetic operations, and “copy” procedures that copy the contents of a source pointer into the array designated by a destination pointer. As in C, it treats an object Ptr of type Pointer as a pointer to the first element of an array, so that for example, adding 1 to Ptr yields a pointer to the second element of the array.

2/5 {*AI12-0445-1*} The generic allows two styles of usage: one in which the array is terminated by a special terminator element; and another in which the programmer keeps track of the length.

Static Semantics

3 The generic library package Interfaces.C.Pointers has the following declaration:

4/5
```
{AI12-0241-1} {AI12-0302-1} generic
   type Index is (<>);
   type Element is private;
   type Element_Array is array (Index range <>) of aliased Element;
   Default_Terminator : Element;
package Interfaces.C.Pointers
   with Preelaborate, Nonblocking, Global => in out synchronized is
```

5
```
   type Pointer is access all Element;
```

6
```
   function Value(Ref        : in Pointer;
                  Terminator : in Element := Default_Terminator)
      return Element_Array;
```

7
```
   function Value(Ref    : in Pointer;
                  Length : in ptrdiff_t)
      return Element_Array;
```

8
```
   Pointer_Error : exception;
```

9
```
   -- C-style Pointer arithmetic
```

10/3
```
   {AI05-0229-1}    function "+" (Left : in Pointer;   Right : in ptrdiff_t) return
   Pointer
         with Convention => Intrinsic;
      function "+" (Left : in ptrdiff_t; Right : in Pointer)   return Pointer
         with Convention => Intrinsic;
      function "-" (Left : in Pointer;   Right : in ptrdiff_t) return Pointer
         with Convention => Intrinsic;
      function "-" (Left : in Pointer;   Right : in Pointer) return ptrdiff_t
         with Convention => Intrinsic;
```

11/3
```
   {AI05-0229-1}    procedure Increment (Ref : in out Pointer)
         with Convention => Intrinsic;
      procedure Decrement (Ref : in out Pointer)
         with Convention => Intrinsic;
```

12/3 *This paragraph was deleted.*{*AI05-0229-1*}

13
```
   function Virtual_Length (Ref        : in Pointer;
                            Terminator : in Element := Default_Terminator)
      return ptrdiff_t;
```

14
```
   procedure Copy_Terminated_Array
      (Source     : in Pointer;
       Target     : in Pointer;
       Limit      : in ptrdiff_t := ptrdiff_t'Last;
       Terminator : in Element :=  Default_Terminator);
```

15
```
   procedure Copy_Array (Source  : in Pointer;
                         Target  : in Pointer;
                         Length  : in ptrdiff_t);
```

16
```
end Interfaces.C.Pointers;
```

The type Pointer is C-compatible and corresponds to one use of C's “Element *”. An object of type Pointer is interpreted as a pointer to the initial Element in an Element_Array. Two styles are supported: 17

- Explicit termination of an array value with Default_Terminator (a special terminator value); 18
- Programmer-managed length, with Default_Terminator treated simply as a data element. 19

```
function Value(Ref        : in Pointer;
               Terminator : in Element := Default_Terminator)
   return Element_Array;
```
20

This function returns an Element_Array whose value is the array pointed to by Ref, up to and including the first Terminator; the lower bound of the array is Index'First. Interfaces.C.Strings.Dereference_Error is propagated if Ref is **null**. 21

```
function Value(Ref    : in Pointer;
               Length : in ptrdiff_t)
   return Element_Array;
```
22

This function returns an Element_Array comprising the first Length elements pointed to by Ref. The exception Interfaces.C.Strings.Dereference_Error is propagated if Ref is **null**. 23

The "+" and "–" functions perform arithmetic on Pointer values, based on the Size of the array elements. In each of these functions, Pointer_Error is propagated if a Pointer parameter is **null**. 24

```
procedure Increment (Ref : in out Pointer);
```
25

Equivalent to Ref := Ref+1. 26

```
procedure Decrement (Ref : in out Pointer);
```
27

Equivalent to Ref := Ref–1. 28

```
function Virtual_Length (Ref        : in Pointer;
                         Terminator : in Element := Default_Terminator)
   return ptrdiff_t;
```
29

Returns the number of Elements, up to the one just before the first Terminator, in Value(Ref, Terminator). 30

```
procedure Copy_Terminated_Array
   (Source     : in Pointer;
    Target     : in Pointer;
    Limit      : in ptrdiff_t := ptrdiff_t'Last;
    Terminator : in Element := Default_Terminator);
```
31

This procedure copies Value(Source, Terminator) into the array pointed to by Target; it stops either after Terminator has been copied, or the number of elements copied is Limit, whichever occurs first. Dereference_Error is propagated if either Source or Target is **null**. 32

Ramification: It is the programmer's responsibility to ensure that elements are not copied beyond the logical length of the target array. 32.a

Implementation Note: The implementation has to take care to check the Limit first. 32.b

```
procedure Copy_Array (Source  : in Pointer;
                      Target  : in Pointer;
                      Length  : in ptrdiff_t);
```
33

This procedure copies the first Length elements from the array pointed to by Source, into the array pointed to by Target. Dereference_Error is propagated if either Source or Target is **null**. 34

Erroneous Execution

It is erroneous to dereference a Pointer that does not designate an aliased Element. 35

35.a **Discussion:** Such a Pointer could arise via "+", "–", Increment, or Decrement.

36 Execution of Value(Ref, Terminator) is erroneous if Ref does not designate an aliased Element in an Element_Array terminated by Terminator.

37 Execution of Value(Ref, Length) is erroneous if Ref does not designate an aliased Element in an Element_Array containing at least Length Elements between the designated Element and the end of the array, inclusive.

38 Execution of Virtual_Length(Ref, Terminator) is erroneous if Ref does not designate an aliased Element in an Element_Array terminated by Terminator.

39 Execution of Copy_Terminated_Array(Source, Target, Limit, Terminator) is erroneous in either of the following situations:

40 • Execution of both Value(Source, Terminator) and Value(Source, Limit) are erroneous, or

41 • Copying writes past the end of the array containing the Element designated by Target.

42 Execution of Copy_Array(Source, Target, Length) is erroneous if either Value(Source, Length) is erroneous, or copying writes past the end of the array containing the Element designated by Target.

43 NOTE To compose a Pointer from an Element_Array, use 'Access on the first element. For example (assuming appropriate instantiations):

44
```
Some_Array   : Element_Array(0..5) ;
Some_Pointer : Pointer := Some_Array(0)'Access;
```

Examples

45 *Example of Interfaces.C.Pointers:*

46
```
with Interfaces.C.Pointers;
with Interfaces.C.Strings;
procedure Test_Pointers is
   package C renames Interfaces.C;
   package Char_Ptrs is
      new C.Pointers (Index              => C.size_t,
                      Element            => C.char,
                      Element_Array      => C.char_array,
                      Default_Terminator => C.nul);
```

47
```
   use type Char_Ptrs.Pointer;
   subtype Char_Star is Char_Ptrs.Pointer;
```

48
```
   procedure Strcpy (Target_Ptr, Source_Ptr : Char_Star) is
      Target_Temp_Ptr : Char_Star := Target_Ptr;
      Source_Temp_Ptr : Char_Star := Source_Ptr;
      Element : C.char;
   begin
      if Target_Temp_Ptr = null or Source_Temp_Ptr = null then
         raise C.Strings.Dereference_Error;
      end if;
```

49/1
```
{8652/0065} {AI95-00142-01}       loop
         Element             := Source_Temp_Ptr.all;
         Target_Temp_Ptr.all := Element;
         exit when C."="(Element, C.nul);
         Char_Ptrs.Increment(Target_Temp_Ptr);
         Char_Ptrs.Increment(Source_Temp_Ptr);
      end loop;
   end Strcpy;
begin
   ...
end Test_Pointers;
```

B.3.3 Unchecked Union Types

{*AI95-00216-01*} {*AI05-0229-1*} {*AI05-0269-1*} [Specifying aspect Unchecked_Union to have the value True defines an interface correspondence between a given discriminated type and some C union. The aspect requires that the associated type shall be given a representation that allocates no space for its discriminant(s).] 1/3

Paragraphs 2 through 3 were moved to Annex J, "Obsolescent Features".

Static Semantics

{*AI05-0229-1*} For a discriminated record type having a variant_part, the following language-defined representation aspect may be specified: 3.1/3

Unchecked_Union 3.2/3

The type of aspect Unchecked_Union is Boolean. If directly specified, the aspect_definition shall be a static expression. If not specified (including by inheritance), the aspect is False.

Aspect Description for Unchecked_Union: Type is used to interface to a C union type. 3.a/3

Legality Rules

Paragraphs 4 and 5 were deleted.

{*AI95-00216-01*} {*AI05-0229-1*} A type for which aspect Unchecked_Union is True is called an *unchecked union type*. A subtype of an unchecked union type is defined to be an *unchecked union subtype*. An object of an unchecked union type is defined to be an *unchecked union object*. 6/3

{*AI95-00216-01*} All component subtypes of an unchecked union type shall be C-compatible. 7/2

{*AI95-00216-01*} If a component subtype of an unchecked union type is subject to a per-object constraint, then the component subtype shall be an unchecked union subtype. 8/2

{*AI95-00216-01*} {*AI05-0026-1*} {*AI12-0174-1*} Any name that denotes a discriminant of an object of an unchecked union type shall occur within the declarative region of the type or as the selector_name of an aggregate, and shall not occur within a record_representation_clause. 9/5

{*AI95-00216-01*} {*AI05-0026-1*} The type of a component declared in a variant_part of an unchecked union type shall not need finalization. In addition to the places where Legality Rules normally apply (see 12.3), this rule also applies in the private part of an instance of a generic unit. For an unchecked union type declared within the body of a generic unit, or within the body of any of its descendant library units, no part of the type of a component declared in a variant_part of the unchecked union type shall be of a formal private type or formal private extension declared within the formal part of the generic unit. 10/3

Reason: {*AI05-0026-1*} The last part is a classic assume-the-worst rule that avoids dependence on the actuals in a generic body. We did not include this in the definition of "needs finalization" as it has a bad interaction with the use of that term for the No_Nested_Finalization restriction. 10.a/3

{*AI95-00216-01*} The completion of an incomplete or private type declaration having a known_discriminant_part shall not be an unchecked union type. 11/2

{*AI95-00216-01*} An unchecked union subtype shall only be passed as a generic actual parameter if the corresponding formal type has no known discriminants or is an unchecked union type. 12/2

Ramification: This includes formal private types without a known_discriminant_part, formal derived types that do not inherit any discriminants (formal derived types do not have known_discriminant_parts), and formal derived types that are unchecked union types. 12.a/2

Static Semantics

13/2 {*AI95-00216-01*} An unchecked union type is eligible for convention C.

14/2 {*AI95-00216-01*} All objects of an unchecked union type have the same size.

15/2 {*AI95-00216-01*} Discriminants of objects of an unchecked union type are of size zero.

16/2 {*AI95-00216-01*} Any check which would require reading a discriminant of an unchecked union object is suppressed (see 11.5). These checks include:

17/5 - {*AI12-0453-1*} The check performed when addressing a variant component (that is, a component that was declared in a variant part) of an unchecked union object that the object has this component (see 4.1.3).

18/2 - Any checks associated with a type or subtype conversion of a value of an unchecked union type (see 4.6). This includes, for example, the check associated with the implicit subtype conversion of an assignment statement.

19/2 - The subtype membership check associated with the evaluation of a qualified expression (see 4.7) or an uninitialized allocator (see 4.8).

19.a/2 **Discussion:** If a suppressed check would have failed, execution is erroneous (see 11.5). An implementation is always allowed to make a suppressed check if it can somehow determine the discriminant value.

Dynamic Semantics

20/2 {*AI95-00216-01*} A view of an unchecked union object (including a type conversion or function call) has *inferable discriminants* if it has a constrained nominal subtype, unless the object is a component of an enclosing unchecked union object that is subject to a per-object constraint and the enclosing object lacks inferable discriminants.

21/2 {*AI95-00216-01*} An expression of an unchecked union type has inferable discriminants if it is either a name of an object with inferable discriminants or a qualified expression whose subtype_mark denotes a constrained subtype.

22/2 {*AI95-00216-01*} Program_Error is raised in the following cases:

23/2 - Evaluation of the predefined equality operator for an unchecked union type if either of the operands lacks inferable discriminants.

24/2 - Evaluation of the predefined equality operator for a type which has a subcomponent of an unchecked union type whose nominal subtype is unconstrained.

25/5 - {*AI12-0162-1*} Evaluation of an individual membership test if the subtype_mark (if any) denotes a constrained unchecked union subtype and the *tested*_simple_expression lacks inferable discriminants.

26/2 - Conversion from a derived unchecked union type to an unconstrained non-unchecked-union type if the operand of the conversion lacks inferable discriminants.

27/2 - Execution of the default implementation of the Write or Read attribute of an unchecked union type.

28/2 - Execution of the default implementation of the Output or Input attribute of an unchecked union type if the type lacks default discriminant values.

Paragraph 29 was deleted.

NOTE {*AI95-00216-01*} The use of an unchecked union to obtain the effect of an unchecked conversion results in erroneous execution (see 11.5). Execution of the following example is erroneous even if Float'Size = Integer'Size: 30/2

```
{AI05-0229-1} type T (Flag : Boolean := False) is                                    31/3
   record
       case Flag is
           when False =>
               F1 : Float := 0.0;
           when True =>
               F2 : Integer := 0;
       end case;
    end record
    with Unchecked_Union;
X : T;                                                                               32/2
Y : Integer := X.F2; -- erroneous
```

Extensions to Ada 95

{*AI95-00216-01*} Pragma Unchecked_Union is new. 32.a/2

Incompatibilities With Ada 2005

{*AI05-0026-1*} **Correction:** The use of discriminants on Unchecked_Union types is now illegal in record_representation_clauses, as it makes no sense to specify a position for something that is not supposed to exist. It is very unlikely that this change will have any impact on existing code. 32.b/3

Extensions to Ada 2005

{*AI05-0229-1*} Aspect Unchecked_Union is new; pragma Unchecked_Union is now obsolescent. 32.c/3

Wording Changes from Ada 2005

{*AI05-0026-1*} **Correction:** Revised the rules to use the "needs finalization" definition, and eliminated generic contract issues. 32.d/3

Wording Changes from Ada 2012

{*AI05-0162-1*} **Correction:** Adjusted the wording to reflect that membership tests can have more than one expression or subtype_mark. 32.e/5

{*AI05-0174-1*} **Correction:** Adjusted the wording to allow named aggregates of an unchecked union type; it is clearly madness to allow positional record components in an aggregate but not named component associations. 32.f/5

B.4 Interfacing with COBOL

{*AI05-0229-1*} The facilities relevant to interfacing with the COBOL language are the package Interfaces.COBOL and support for specifying the Convention aspect with *convention*_identifier COBOL. 1/3

The COBOL interface package supplies several sets of facilities: 2

- A set of types corresponding to the native COBOL types of the supported COBOL implementation (so-called "internal COBOL representations"), allowing Ada data to be passed as parameters to COBOL programs 3
- {*AI12-0439-1*} A set of types and constants reflecting external data representations such as can be found in files or databases, allowing COBOL-generated data to be read by an Ada program, and Ada-generated data to be read by COBOL programs 4/5
- A generic package for converting between an Ada decimal type value and either an internal or external COBOL representation 5

Static Semantics

The library package Interfaces.COBOL has the following declaration: 6

```
{AI12-0241-1} {AI12-0302-1} package Interfaces.COBOL                                 7/5
   with Preelaborate, Nonblocking, Global => in out synchronized is
   -- Types and operations for internal data representations                         8
```

```
9          type Floating      is digits implementation-defined;
           type Long_Floating is digits implementation-defined;

10         type Binary      is range implementation-defined;
           type Long_Binary is range implementation-defined;

11         Max_Digits_Binary      : constant := implementation-defined;
           Max_Digits_Long_Binary : constant := implementation-defined;

```

Implementation defined: The types Floating, Long_Floating, Binary, Long_Binary, Decimal_Element, and COBOL_Character; and the initializations of the variables Ada_To_COBOL and COBOL_To_Ada, in Interfaces.COBOL. 50.a/1

Each of the types in Interfaces.COBOL is COBOL-compatible. 51

The types Floating and Long_Floating correspond to the native types in COBOL for data items with computational usage implemented by floating point. The types Binary and Long_Binary correspond to the native types in COBOL for data items with binary usage, or with computational usage implemented by binary. 52

Max_Digits_Binary is the largest number of decimal digits in a numeric value that is represented as Binary. Max_Digits_Long_Binary is the largest number of decimal digits in a numeric value that is represented as Long_Binary. 53

The type Packed_Decimal corresponds to COBOL's packed-decimal usage. 54

The type COBOL_Character defines the run-time character set used in the COBOL implementation. Ada_To_COBOL and COBOL_To_Ada are the mappings between the Ada and COBOL run-time character sets. 55

Reason: The character mappings are visible variables, since the user needs the ability to modify them at run time. 55.a

Type Alphanumeric corresponds to COBOL's alphanumeric data category. 56

Each of the functions To_COBOL and To_Ada converts its parameter based on the mappings Ada_To_COBOL and COBOL_To_Ada, respectively. The length of the result for each is the length of the parameter, and the lower bound of the result is 1. Each component of the result is obtained by applying the relevant mapping to the corresponding component of the parameter. 57

Each of the procedures To_COBOL and To_Ada copies converted elements from Item to Target, using the appropriate mapping (Ada_To_COBOL or COBOL_To_Ada, respectively). The index in Target of 58

the last element assigned is returned in Last (0 if Item is a null array). If Item'Length exceeds Target'Length, Constraint_Error is propagated.

59 Type Numeric corresponds to COBOL's numeric data category with display usage.

60 The types Display_Format, Binary_Format, and Packed_Format are used in conversions between Ada decimal type values and COBOL internal or external data representations. The value of the constant Native_Binary is either High_Order_First or Low_Order_First, depending on the implementation.

61
```
function Valid (Item   : in Numeric;
                Format : in Display_Format) return Boolean;
```

62 The function Valid checks that the Item parameter has a value consistent with the value of Format. If the value of Format is other than Unsigned, Leading_Separate, and Trailing_Separate, the effect is implementation defined. If Format does have one of these values, the following rules apply:

63/3 - {*8652/0066*} {*AI95-00071-01*} {*AI05-0264-1*} Format=Unsigned: if Item comprises one or more decimal digit characters, then Valid returns True, else it returns False.

64/1 - {*8652/0066*} {*AI95-00071-01*} Format=Leading_Separate: if Item comprises a single occurrence of the plus or minus sign character, and then one or more decimal digit characters, then Valid returns True, else it returns False.

65/1 - {*8652/0066*} {*AI95-00071-01*} Format=Trailing_Separate: if Item comprises one or more decimal digit characters and finally a plus or minus sign character, then Valid returns True, else it returns False.

66
```
function Length (Format : in Display_Format) return Natural;
```

67 The Length function returns the minimal length of a Numeric value sufficient to hold any value of type Num when represented as Format.

68
```
function To_Decimal (Item   : in Numeric;
                     Format : in Display_Format) return Num;
```

69 Produces a value of type Num corresponding to Item as represented by Format. The number of digits after the assumed radix point in Item is Num'Scale. Conversion_Error is propagated if the value represented by Item is outside the range of Num.

69.a **Discussion:** There is no issue of truncation versus rounding, since the number of decimal places is established by Num'Scale.

70
```
function To_Display (Item   : in Num;
                     Format : in Display_Format) return Numeric;
```

71/1 {*8652/0067*} {*AI95-00072-01*} This function returns the Numeric value for Item, represented in accordance with Format. The length of the returned value is Length(Format), and the lower bound is 1. Conversion_Error is propagated if Num is negative and Format is Unsigned.

72
```
function Valid (Item   : in Packed_Decimal;
                Format : in Packed_Format) return Boolean;
```

73 This function returns True if Item has a value consistent with Format, and False otherwise. The rules for the formation of Packed_Decimal values are implementation defined.

74
```
function Length (Format : in Packed_Format) return Natural;
```

75 This function returns the minimal length of a Packed_Decimal value sufficient to hold any value of type Num when represented as Format.

```
function To_Decimal (Item   : in Packed_Decimal;                                    76
                     Format : in Packed_Format) return Num;
```

Produces a value of type Num corresponding to Item as represented by Format. Num'Scale is the number of digits after the assumed radix point in Item. Conversion_Error is propagated if the value represented by Item is outside the range of Num. 77

```
function To_Packed (Item   : in Num;                                                78
                    Format : in Packed_Format) return Packed_Decimal;
```

{*8652/0067*} {*AI95-00072-01*} This function returns the Packed_Decimal value for Item, represented in accordance with Format. The length of the returned value is Length(Format), and the lower bound is 1. Conversion_Error is propagated if Num is negative and Format is Packed_Unsigned. 79/1

```
function Valid (Item   : in Byte_Array;                                             80
                Format : in Binary_Format) return Boolean;
```

This function returns True if Item has a value consistent with Format, and False otherwise. 81

Ramification: This function returns False only when the represented value is outside the range of Num. 81.a

```
function Length (Format : in Binary_Format) return Natural;                         82
```

This function returns the minimal length of a Byte_Array value sufficient to hold any value of type Num when represented as Format. 83

```
function To_Decimal (Item   : in Byte_Array;                                        84
                     Format : in Binary_Format) return Num;
```

Produces a value of type Num corresponding to Item as represented by Format. Num'Scale is the number of digits after the assumed radix point in Item. Conversion_Error is propagated if the value represented by Item is outside the range of Num. 85

```
function To_Binary (Item   : in Num;                                                86
                    Format : in Binary_Format) return Byte_Array;
```

{*8652/0067*} {*AI95-00072-01*} This function returns the Byte_Array value for Item, represented in accordance with Format. The length of the returned value is Length(Format), and the lower bound is 1. 87/1

```
function To_Decimal (Item : in Binary)      return Num;                             88

function To_Decimal (Item : in Long_Binary) return Num;
```

These functions convert from COBOL binary format to a corresponding value of the decimal type Num. Conversion_Error is propagated if Item is too large for Num. 89

Ramification: There is no rescaling performed on the conversion. That is, the returned value in each case is a “bit copy” if Num has a binary radix. The programmer is responsible for maintaining the correct scale. 89.a

```
function To_Binary      (Item : in Num)  return Binary;                             90

function To_Long_Binary (Item : in Num)  return Long_Binary;
```

These functions convert from Ada decimal to COBOL binary format. Conversion_Error is propagated if the value of Item is too large to be represented in the result type. 91

Discussion: One style of interface supported for COBOL, similar to what is provided for C, is the ability to call and pass parameters to an existing COBOL program. Thus the interface package supplies types that can be used in an Ada program as parameters to subprograms whose bodies will be in COBOL. These types map to COBOL's alphanumeric and numeric data categories. 91.a

Several types are provided for support of alphanumeric data. Since COBOL's run-time character set is not necessarily the same as Ada's, Interfaces.COBOL declares an implementation-defined character type COBOL_Character, and mappings between Character and COBOL_Character. These mappings are visible variables (rather than, say, functions 91.b

or constant arrays), since in the situation where COBOL_Character is EBCDIC, the flexibility of dynamically modifying the mappings is needed. Corresponding to COBOL's alphanumeric data is the string type Alphanumeric.

91.c Numeric data may have either a “display” or “computational” representation in COBOL. On the Ada side, the data is of a decimal fixed point type. Passing an Ada decimal data item to a COBOL program requires conversion from the Ada decimal type to some type that reflects the representation expected on the COBOL side.

91.d • Computational Representation

91.e Floating point representation is modeled by Ada floating point types, Floating and Long_Floating. Conversion between these types and Ada decimal types is obtained directly, since the type name serves as a conversion function.

91.f Binary representation is modeled by an Ada integer type, Binary, and possibly other types such as Long_Binary. Conversion between, say, Binary and a decimal type is through functions from an instantiation of the generic package Decimal_Conversions.

91.g Packed decimal representation is modeled by the Ada array type Packed_Decimal. Conversion between packed decimal and a decimal type is through functions from an instantiation of the generic package Decimal_Conversions.

91.h • Display Representation

91.i Display representation for numeric data is modeled by the array type Numeric. Conversion between display representation and a decimal type is through functions from an instantiation of the generic package Decimal_Conversions. A parameter to the conversion function indicates the desired interpretation of the data (e.g., signed leading separate, etc.)

91.j/3 {*AI05-0229-1*} The Convention of a record type may be specified as COBOL to direct the compiler to choose a COBOL-compatible representation for objects of the type.

91.k The package Interfaces.COBOL allows the Ada programmer to deal with data from files (or databases) created by a COBOL program. For data that is alphanumeric, or in display or packed decimal format, the approach is the same as for passing parameters (instantiate Decimal_Conversions to obtain the needed conversion functions). For binary data, the external representation is treated as a Byte array, and an instantiation of Decimal_IO produces a package that declares the needed conversion functions. A parameter to the conversion function indicates the desired interpretation of the data (e.g., high- versus low-order byte first).

Implementation Requirements

92/3 {*AI05-0229-1*} An implementation shall support specifying aspect Convention with a COBOL *convention*_identifier for a COBOL-eligible type (see B.1).

92.a **Ramification:** An implementation supporting this package shall ensure that if the bounds of a Packed_Decimal, Alphanumeric, or Numeric variable are static, then the representation of the object comprises solely the array components (that is, there is no implicit run-time “descriptor” that is part of the object).

Implementation Permissions

93 An implementation may provide additional constants of the private types Display_Format, Binary_Format, or Packed_Format.

93.a **Reason:** This is to allow exploitation of other external formats that may be available in the COBOL implementation.

94 An implementation may provide further floating point and integer types in Interfaces.COBOL to match additional native COBOL types, and may also supply corresponding conversion functions in the generic package Decimal_Conversions.

Implementation Advice

95 An Ada implementation should support the following interface correspondences between Ada and COBOL.

96 • An Ada **access** T parameter is passed as a “BY REFERENCE” data item of the COBOL type corresponding to T.

97 • An Ada **in** scalar parameter is passed as a “BY CONTENT” data item of the corresponding COBOL type.

- Any other Ada parameter is passed as a “BY REFERENCE” data item of the COBOL type corresponding to the Ada parameter type; for scalars, a local copy is used if necessary to ensure by-copy semantics. 98

Implementation Advice: If COBOL interfacing is supported, the interface correspondences between Ada and COBOL should be supported. 98.a/2

NOTE 1 {*AI05-0229-1*} An implementation is not required to support specifying aspect Convention for access types, nor is it required to support specifying aspects Import, Export, or Convention for functions. 99/3

Reason: COBOL does not have a pointer facility, and a COBOL program does not return a value. 99.a

NOTE 2 {*AI12-0440-1*} If an Ada subprogram is exported to COBOL, then a call from COBOL call can specify either “BY CONTENT” or “BY REFERENCE”. 100/5

Examples

Examples of Interfaces.COBOL: 101

```
with Interfaces.COBOL;                                                          102
procedure Test_Call is

   -- Calling a foreign COBOL program                                           103
   -- Assume that a COBOL program PROG has the following declaration
   --  in its LINKAGE section:
   --  01 Parameter-Area
   --    05 NAME   PIC X(20).
   --    05 SSN    PIC X(9).
   --    05 SALARY PIC 99999V99 USAGE COMP.
   -- The effect of PROG is to update SALARY based on some algorithm

   package COBOL renames Interfaces.COBOL;                                      104

   type Salary_Type is delta 0.01 digits 7;                                     105

{AI05-0229-1}     type COBOL_Record is                                          106/3
      record
         Name   : COBOL.Numeric(1..20);
         SSN    : COBOL.Numeric(1..9);
         Salary : COBOL.Binary;  -- Assume Binary = 32 bits
      end record
      with Convention => COBOL;

{AI05-0229-1}     procedure Prog (Item : in out COBOL_Record)                   107/3
      with Import => True, Convention => COBOL;

   package Salary_Conversions is                                                108
      new COBOL.Decimal_Conversions(Salary_Type);

   Some_Salary : Salary_Type := 12_345.67;                                      109
   Some_Record : COBOL_Record :=
      (Name   => "Johnson, John       ",
       SSN    => "111223333",
       Salary => Salary_Conversions.To_Binary(Some_Salary));

begin                                                                           110
   Prog (Some_Record);
   ...
end Test_Call;

with Interfaces.COBOL;                                                          111
with COBOL_Sequential_IO; -- Assumed to be supplied by implementation
procedure Test_External_Formats is

{AI12-0442-1}     -- Using data created by a COBOL program                      112/5
   -- Assume that a COBOL program has created a sequential file with
   --  the following record structure, and that we want
   --  process the records in an Ada program
   --  01 EMPLOYEE-RECORD
   --    05 NAME    PIC X(20).
   --    05 SSN     PIC X(9).
   --    05 SALARY  PIC 99999V99 USAGE COMP.
   --    05 ADJUST  PIC S999V999 SIGN LEADING SEPARATE.
   -- The COMP data is binary (32 bits), high-order byte first
```

```
   package COBOL renames Interfaces.COBOL;

   type Salary_Type      is delta 0.01  digits 7;
   type Adjustments_Type is delta 0.001 digits 6;

{AI05-0229-1}    type COBOL_Employee_Record_Type is  -- External representation
      record
         Name    : COBOL.Alphanumeric(1..20);
         SSN     : COBOL.Alphanumeric(1..9);
         Salary  : COBOL.Byte_Array(1..4);
         Adjust  : COBOL.Numeric(1..7);  -- Sign and 6 digits
      end record
      with Convention => COBOL;

   Open (COBOL_File, Name => "Some_File");

   loop
     Read (COBOL_File, COBOL_Record);

{AI12-0178-1}      Ada_Record.Name := COBOL.To_Ada(COBOL_Record.Name);
     Ada_Record.SSN  := COBOL.To_Ada(COBOL_Record.SSN);
     Ada_Record.Salary :=
        To_Decimal(COBOL_Record.Salary, COBOL.High_Order_First);
     Ada_Record.Adjust :=
        To_Decimal(COBOL_Record.Adjust, COBOL.Leading_Separate);
     ... -- Process Ada_Record
   end loop;
exception
   when End_Error => ...
end Test_External_Formats;
```

Wording Changes from Ada 95

{*8652/0066*} {*AI95-00071-01*} **Corrigendum:** Corrected the definition of Valid to match COBOL.

{*8652/0067*} {*AI95-00072-01*} **Corrigendum:** Specified the bounds of the results of To_Display, To_Packed, and To_Binary.

B.5 Interfacing with Fortran

{*AI05-0229-1*} The facilities relevant to interfacing with the Fortran language are the package Interfaces.Fortran and support for specifying the Convention aspect with *convention*_identifier Fortran.

The package Interfaces.Fortran defines Ada types whose representations are identical to the default representations of the Fortran intrinsic types Integer, Real, Double Precision, Complex, Logical, and

Character in a supported Fortran implementation. These Ada types can therefore be used to pass objects between Ada and Fortran programs.

Static Semantics

The library package Interfaces.Fortran has the following declaration: 3

```
{AI12-0414-1} with Ada.Numerics.Generic_Complex_Types;  -- see G.1.1                4/5
pragma Elaborate_All(Ada.Numerics.Generic_Complex_Types);
package Interfaces.Fortran
   with Pure is

   type Fortran_Integer is range implementation-defined;                             5

   type Real             is digits implementation-defined;                           6
   type Double_Precision is digits implementation-defined;

   type Logical is new Boolean;                                                      7

   package Single_Precision_Complex_Types is                                         8
      new Ada.Numerics.Generic_Complex_Types (Real);

   type Complex is new Single_Precision_Complex_Types.Complex;                       9

   subtype Imaginary is Single_Precision_Complex_Types.Imaginary;                    10
   i : Imaginary renames Single_Precision_Complex_Types.i;
   j : Imaginary renames Single_Precision_Complex_Types.j;

{AI12-0058-1}    package Double_Precision_Complex_Types is                          10.1/5
      new Ada.Numerics.Generic_Complex_Types (Double_Precision);

{AI12-0058-1}    type Double_Complex is new Double_Precision_Complex_Types.Complex; 10.2/5

{AI12-0058-1}    subtype Double_Imaginary is                                        10.3/5
Double_Precision_Complex_Types.Imaginary;

   type Character_Set is implementation-defined character type;                      11

{AI05-0229-1}    type Fortran_Character is array (Positive range <>) of             12/3
Character_Set
      with Pack;

   function To_Fortran (Item : in Character) return Character_Set;                   13
   function To_Ada (Item : in Character_Set) return Character;

   function To_Fortran (Item : in String) return Fortran_Character;                  14
   function To_Ada     (Item : in Fortran_Character) return String;

   procedure To_Fortran (Item       : in String;                                     15
                         Target     : out Fortran_Character;
                         Last       : out Natural);

   procedure To_Ada (Item     : in Fortran_Character;                                16
                     Target   : out String;
                     Last     : out Natural);

end Interfaces.Fortran;                                                              17
```

Implementation defined: The types Fortran_Integer, Real, Double_Precision, and Character_Set in Interfaces.Fortran. 17.a.1/1

Ramification: {*AI12-0058-1*} The means by which the Complex and Double_Complex types are provided in Interfaces.Fortran creates a dependence of Interfaces.Fortran on Numerics.Generic_Complex_Types (see G.1.1). This dependence is intentional and unavoidable, if the Fortran-compatible Complex and Double_Complex types are to be useful in Ada code without duplicating facilities defined elsewhere. 17.a/5

{*AI12-0058-1*} The types Fortran_Integer, Real, Double_Precision, Logical, Complex, Double_Complex, Character_Set, and Fortran_Character are Fortran-compatible. 18/5

The To_Fortran and To_Ada functions map between the Ada type Character and the Fortran type Character_Set, and also between the Ada type String and the Fortran type Fortran_Character. The To_Fortran and To_Ada procedures have analogous effects to the string conversion subprograms found in Interfaces.COBOL. 19

Implementation Requirements

20/3 {*AI05-0229-1*} An implementation shall support specifying aspect Convention with a Fortran *convention*_identifier for a Fortran-eligible type (see B.1).

Implementation Permissions

21/5 {*AI12-0058-1*} {*AI12-0263-1*} {*AI12-0450-1*} An implementation may add additional declarations to the Fortran interface packages. For example, declarations are permitted for the character types corresponding to Fortran character kinds 'ascii' and 'iso_10646', which in turn correspond to ISO/IEC 646:1991 and to UCS-4 as specified in ISO/IEC 10646:2020.

21.a.1/5 **Reason:** {*AI12-0058-1*} Fortran compilers are required to recognize 'ascii' and 'iso_10646' as arguments to the SELECTED_CHAR_KIND intrinsic function, but are not required to support those kinds.

21.a/5 **Discussion:** {*AI12-0058-1*} Implementations may add auxiliary declarations as needed to assist in the declarations of additional Fortran-compatible types. For example, if a wide character type is defined to match a Fortran 90 wide character type (accessible in Fortran 90 with the Kind attribute), then an auxiliary character set may be declared to serve as its component type.

Implementation Advice

22 An Ada implementation should support the following interface correspondences between Ada and Fortran:

23 • An Ada procedure corresponds to a Fortran subroutine.

24 • An Ada function corresponds to a Fortran function.

25 • An Ada parameter of an elementary, array, or record type T is passed as a T_F argument to a Fortran procedure, where T_F is the Fortran type corresponding to the Ada type T, and where the INTENT attribute of the corresponding dummy argument matches the Ada formal parameter mode; the Fortran implementation's parameter passing conventions are used. For elementary types, a local copy is used if necessary to ensure by-copy semantics.

26 • An Ada parameter of an access-to-subprogram type is passed as a reference to a Fortran procedure whose interface corresponds to the designated subprogram's specification.

26.a/2 **Implementation Advice:** If Fortran interfacing is supported, the interface correspondences between Ada and Fortran should be supported.

27 NOTE 1 An object of a Fortran-compatible record type, declared in a library package or subprogram, can correspond to a Fortran common block; the type also corresponds to a Fortran “derived type”.

28/5 NOTE 2 {*AI12-0224-1*} For Fortran facilities not addressed by this subclause, consider using the Fortran to C interoperability features defined in ISO/IEC 1594-1:2018 along with the C interfacing features defined in B.3.

Examples

29 *Example of Interfaces.Fortran:*

30
```
with Interfaces.Fortran;
use Interfaces.Fortran;
procedure Ada_Application is
```

31/5
```
{AI05-0229-1} {AI12-0178-1}    type Fortran_Matrix is
      array (Fortran_Integer range <>,
             Fortran_Integer range <>) of Double_Precision
      with Convention => Fortran;                    -- stored in Fortran's
                                                     -- column-major order
   procedure Invert (Rank : in Fortran_Integer; X : in out Fortran_Matrix)
      with Import => True, Convention => Fortran; -- a Fortran subroutine
```

32
```
   Rank      : constant Fortran_Integer := 100;
   My_Matrix : Fortran_Matrix (1 .. Rank, 1 .. Rank);
```

```
{AI12-0058-1}    Precision: constant := 6;                                    33/5
   type Standard_Deviation is digits Precision
      with Convention => Fortran;
   Deviation : Standard_Deviation;
      -- Declarations to match the following Fortran declarations:
      --   integer, parameter :: precision = selected_real_kind(p=6)
      --   real(precision) :: deviation
begin                                                                         34
   ...                                                                        35
   My_Matrix := ...;
   ...
   Invert (Rank, My_Matrix);
   ...
{AI12-0058-1}    Deviation := ...;                                           36/5
   ...
end Ada_Application;                                                          37
```

Wording Changes from Ada 2012

{*AI12-0058-1*} **Correction:** The package Double_Precision_Complex_Types and associated types are added to package Interfaces.Fortran. In unusual circumstances, this could cause an incompatibility; we don't document it as an incompatibility as implementations are allowed to add declarations to this package, so that risk of an incompatibility is present for any move from one version of an implementation to another (not to mention to another implementation). As such, the language-defined additions make no change in the risk of incompatibility. 37.a/5

Annex C
(normative)
Systems Programming

[The Systems Programming Annex specifies additional capabilities provided for low-level programming. These capabilities are also required in many real-time, embedded, distributed, and information systems.] 1

Extensions to Ada 83

This Annex is new to Ada 95. 1.a

C.1 Access to Machine Operations

{*AI05-0299-1*} [This subclause specifies rules regarding access to machine instructions from within an Ada program.] 1/3

Implementation defined: Implementation-defined intrinsic subprograms. 1.a/2

Implementation Requirements

{*AI12-0320-1*} The implementation shall support machine code insertions (see 13.8) or intrinsic subprograms (see 6.3.1) (or both). The implementation shall allow the use of Ada entities as operands for such machine code insertions or intrinsic subprograms. 2/5

Discussion: {*AI12-0320-1*} Ada entities could be used as operands in machine code insertions and/or intrinsic subprograms using language-defined attributes (such as address), implementation-defined attributes, or could be directly allowed. 2.a/5

Implementation Advice

The machine code or intrinsics support should allow access to all operations normally available to assembly language programmers for the target environment, including privileged instructions, if any. 3

Implementation Advice: The machine code or intrinsics support should allow access to all operations normally available to assembly language programmers for the target environment. 3.a.1/2

Ramification: Of course, on a machine with protection, an attempt to execute a privileged instruction in user mode will probably trap. Nonetheless, we want implementations to provide access to them so that Ada can be used to write systems programs that run in privileged mode. 3.a

{*AI05-0229-1*} The support for interfacing aspects (see Annex B) should include interface to assembler; the default assembler should be associated with the convention identifier Assembler. 4/3

Implementation Advice: Interface to assembler should be supported; the default assembler should be associated with the convention identifier Assembler. 4.a/2

If an entity is exported to assembly language, then the implementation should allocate it at an addressable location, and should ensure that it is retained by the linking process, even if not otherwise referenced from the Ada code. The implementation should assume that any call to a machine code or assembler subprogram is allowed to read or update every object that is specified as exported. 5

Implementation Advice: If an entity is exported to assembly language, then the implementation should allocate it at an addressable location even if not otherwise referenced from the Ada code. A call to a machine code or assembler subprogram should be treated as if it can read or update every object that is specified as exported. 5.a/5

Documentation Requirements

The implementation shall document the overhead associated with calling machine-code or intrinsic subprograms, as compared to a fully-inlined call, and to a regular out-of-line call. 6

6.a/2 **Documentation Requirement:** The overhead of calling machine-code or intrinsic subprograms.

7 The implementation shall document the types of the package System.Machine_Code usable for machine code insertions, and the attributes to be used in machine code insertions for references to Ada entities.

7.a/2 **Documentation Requirement:** The types and attributes used in machine code insertions.

8/3 {*AI05-0229-1*} The implementation shall document the subprogram calling conventions associated with the convention identifiers available for use with the Convention aspect (Ada and Assembler, at a minimum), including register saving, exception propagation, parameter passing, and function value returning.

8.a/2 **Documentation Requirement:** The subprogram calling conventions for all supported convention identifiers.

9 For exported and imported subprograms, the implementation shall document the mapping between the Link_Name string, if specified, or the Ada designator, if not, and the external link name used for such a subprogram.

9.a/2 *This paragraph was deleted.*

9.b/2 **Documentation Requirement:** The mapping between the Link_Name or Ada designator and the external link name.

Implementation Advice

10 The implementation should ensure that little or no overhead is associated with calling intrinsic and machine-code subprograms.

10.a/2 **Implementation Advice:** Little or no overhead should be associated with calling intrinsic and machine-code subprograms.

11 It is recommended that intrinsic subprograms be provided for convenient access to any machine operations that provide special capabilities or efficiency and that are not otherwise available through the language constructs. Examples of such instructions include:

12/5 • {*AI12-0453-1*} Atomic read-modify-write operations — for example, test and set, compare and swap, decrement and test, enqueue/dequeue.

13/5 • {*AI12-0453-1*} Standard numeric functions — for example, *sin*, *log*.

14/5 • {*AI12-0453-1*} String manipulation operations — for example, translate and test.

15/5 • {*AI12-0453-1*} Vector operations — for example, compare vector against thresholds.

16 • Direct operations on I/O ports.

16.a/2 **Implementation Advice:** Intrinsic subprograms should be provided to access any machine operations that provide special capabilities or efficiency not normally available.

C.2 Required Representation Support

1/3 {*AI95-00434-01*} {*AI05-0299-1*} This subclause specifies minimal requirements on the support for representation items and related features.

Implementation Requirements

2 The implementation shall support at least the functionality defined by the recommended levels of support in Clause 13.

C.3 Interrupt Support

1/3 {*AI05-0299-1*} [This subclause specifies the language-defined model for hardware interrupts in addition to mechanisms for handling interrupts.]

Dynamic Semantics

[An *interrupt* represents a class of events that are detected by the hardware or the system software.] Interrupts are said to occur. An *occurrence* of an interrupt is separable into generation and delivery. *Generation* of an interrupt is the event in the underlying hardware or system that makes the interrupt available to the program. *Delivery* is the action that invokes part of the program as response to the interrupt occurrence. Between generation and delivery, the interrupt occurrence [(or interrupt)] is *pending*. Some or all interrupts may be *blocked*. When an interrupt is blocked, all occurrences of that interrupt are prevented from being delivered. Certain interrupts are *reserved*. The set of reserved interrupts is implementation defined. A reserved interrupt is either an interrupt for which user-defined handlers are not supported, or one which already has an attached handler by some other implementation-defined means. Program units can be connected to nonreserved interrupts. While connected, the program unit is said to be *attached* to that interrupt. The execution of that program unit, the *interrupt handler*, is invoked upon delivery of the interrupt occurrence. 2

This paragraph was deleted. 2.a/2

To be honest: As an obsolescent feature, interrupts may be attached to task entries by an address clause. See J.7.1. 2.b

While a handler is attached to an interrupt, it is called once for each delivered occurrence of that interrupt. While the handler executes, the corresponding interrupt is blocked. 3

While an interrupt is blocked, all occurrences of that interrupt are prevented from being delivered. Whether such occurrences remain pending or are lost is implementation defined. 4

Each interrupt has a *default treatment* which determines the system's response to an occurrence of that interrupt when no user-defined handler is attached. The set of possible default treatments is implementation defined, as is the method (if one exists) for configuring the default treatments for interrupts. 5

An interrupt is delivered to the handler (or default treatment) that is in effect for that interrupt at the time of delivery. 6

An exception propagated from a handler that is invoked by an interrupt has no effect. 7

[If the Ceiling_Locking policy (see D.3) is in effect, the interrupt handler executes with the active priority that is the ceiling priority of the corresponding protected object.] 8

Implementation Requirements

{*AI12-0445-1*} The implementation shall provide a mechanism to determine the minimum stack space that is necessary for each interrupt handler and to reserve that space for the execution of the handler. [This space should accommodate nested invocations of the handler where the system permits this.] 9/5

If the hardware or the underlying system holds pending interrupt occurrences, the implementation shall provide for later delivery of these occurrences to the program. 10

If the Ceiling_Locking policy is not in effect, the implementation shall provide means for the application to specify whether interrupts are to be blocked during protected actions. 11

Documentation Requirements

The implementation shall document the following items: 12

Discussion: This information may be different for different forms of interrupt handlers. 12.a

1. For each interrupt, which interrupts are blocked from delivery when a handler attached to that interrupt executes (either as a result of an interrupt delivery or of an ordinary call on a procedure of the corresponding protected object). 13

14 2. Any interrupts that cannot be blocked, and the effect of attaching handlers to such interrupts, if this is permitted.

15 3. Which run-time stack an interrupt handler uses when it executes as a result of an interrupt delivery; if this is configurable, what is the mechanism to do so; how to specify how much space to reserve on that stack.

16/5 4. {*AI12-0453-1*} Any implementation- or hardware-specific activity that happens before a user-defined interrupt handler gets control (for example, reading device registers, acknowledging devices).

17 5. Any timing or other limitations imposed on the execution of interrupt handlers.

18 6. The state (blocked/unblocked) of the nonreserved interrupts when the program starts; if some interrupts are unblocked, what is the mechanism a program can use to protect itself before it can attach the corresponding handlers.

19 7. Whether the interrupted task is allowed to resume execution before the interrupt handler returns.

20/5 8. {*AI12-0453-1*} The treatment of interrupt occurrences that are generated while the interrupt is blocked; that is, whether one or more occurrences are held for later delivery, or all are lost.

21 9. Whether predefined or implementation-defined exceptions are raised as a result of the occurrence of any interrupt, and the mapping between the machine interrupts (or traps) and the predefined exceptions.

22 10. On a multi-processor, the rules governing the delivery of an interrupt to a particular processor.

22.a/2 **Documentation Requirement:** The treatment of interrupts.

Implementation Permissions

23/2 {*AI95-00434-01*} If the underlying system or hardware does not allow interrupts to be blocked, then no blocking is required [as part of the execution of subprograms of a protected object for which one of its subprograms is an interrupt handler].

24 In a multi-processor with more than one interrupt subsystem, it is implementation defined whether (and how) interrupt sources from separate subsystems share the same Interrupt_Id type (see C.3.2). In particular, the meaning of a blocked or pending interrupt may then be applicable to one processor only.

24.a **Discussion:** This issue is tightly related to the issue of scheduling on a multi-processor. In a sense, if a particular interrupt source is not available to all processors, the system is not truly homogeneous.

24.b/5 {*AI12-0453-1*} One way to approach this problem is to assign sub-ranges within Interrupt_Id to each interrupt subsystem, such that “similar” interrupt sources (for example a timer) in different subsystems get a distinct id.

25 Implementations are allowed to impose timing or other limitations on the execution of interrupt handlers.

25.a **Reason:** These limitations are often necessary to ensure proper behavior of the implementation.

26/3 {*AI95-00434-01*} {*AI05-0299-1*} Other forms of handlers are allowed to be supported, in which case the rules of this subclause should be adhered to.

27 The active priority of the execution of an interrupt handler is allowed to vary from one occurrence of the same interrupt to another.

Implementation Advice

28/2 {*AI95-00434-01*} If the Ceiling_Locking policy is not in effect, the implementation should provide means for the application to specify which interrupts are to be blocked during protected actions, if the underlying system allows for finer-grained control of interrupt blocking.

Implementation Advice: If the Ceiling_Locking policy is not in effect and the target system allows for finer-grained control of interrupt blocking, a means for the application to specify which interrupts are to be blocked during protected actions should be provided. 28.a/2

NOTE 1 {*AI12-0447-1*} The default treatment for an interrupt can be to keep the interrupt pending or to deliver it to an implementation-defined handler. Examples of actions that an implementation-defined handler can perform include aborting the partition, ignoring (that is, discarding occurrences of) the interrupt, or queuing one or more occurrences of the interrupt for possible later delivery when a user-defined handler is attached to that interrupt. 29/5

NOTE 2 It is a bounded error to call Task_Identification.Current_Task (see C.7.1) from an interrupt handler. 30

NOTE 3 The rule that an exception propagated from an interrupt handler has no effect is modeled after the rule about exceptions propagated out of task bodies. 31

C.3.1 Protected Procedure Handlers

Paragraphs 1 through 6 were moved to Annex J, "Obsolescent Features".

Static Semantics

{*AI05-0229-1*} For a parameterless protected procedure, the following language-defined representation aspects may be specified: 6.1/3

Interrupt_Handler 6.2/3

The type of aspect Interrupt_Handler is Boolean. If directly specified, the aspect_definition shall be a static expression. [This aspect is never inherited;] if not directly specified, the aspect is False.

Aspect Description for Interrupt_Handler: Protected procedure may be attached to interrupts. 6.a/3

Attach_Handler 6.3/3

The aspect Attach_Handler is an expression, which shall be of type Interrupts.Interrupt_Id. [This aspect is never inherited.]

Aspect Description for Attach_Handler: Protected procedure is attached to an interrupt. 6.b/3

Legality Rules

{*AI95-00434-01*} {*AI05-0033-1*} {*AI05-0229-1*} If either the Attach_Handler or Interrupt_Handler aspect are specified for a protected procedure, the corresponding protected_type_declaration or single_-protected_declaration shall be a library-level declaration and shall not be declared within a generic body. In addition to the places where Legality Rules normally apply (see 12.3), this rule also applies in the private part of an instance of a generic unit. 7/3

Discussion: In the case of a protected_type_declaration, an object_declaration of an object of that type need not be at library level. 7.a

{*AI05-0033-1*} {*AI05-0229-1*} We cannot allow these aspects in protected declarations in a generic body, because legality rules are not checked for instance bodies, and these should not be allowed if the instance is not at the library level. The protected types can be declared in the private part if this is desired. Note that while the 'Access to use the handler would provide the check in the case of Interrupt_Handler, there is no other check for Attach_Handler. Since these aspects are so similar, we want the rules to be the same. 7.b/3

This paragraph was deleted.{*AI95-00253-01*} {*AI95-00303-01*} {*AI05-0033-1*} 8/3

Dynamic Semantics

{*AI05-0229-1*} If the Interrupt_Handler aspect of a protected procedure is True, then the procedure may be attached dynamically, as a handler, to interrupts (see C.3.2). [Such procedures are allowed to be attached to multiple interrupts.] 9/3

{*AI05-0229-1*} The expression specified for the Attach_Handler aspect of a protected procedure *P* is evaluated as part of the creation of the protected object that contains *P*. The value of the expression identifies an interrupt. As part of the initialization of that object, *P* (the *handler* procedure) is attached to 10/3

the identified interrupt. A check is made that the corresponding interrupt is not reserved. Program_Error is raised if the check fails, and the existing treatment for the interrupt is not affected.

11/3 {*AI95-00434-01*} {*AI05-0229-1*} If the Ceiling_Locking policy (see D.3) is in effect, then upon the initialization of a protected object that contains a protected procedure for which either the Attach_Handler aspect is specified or the Interrupt_Handler aspect is True, a check is made that the initial ceiling priority of the object is in the range of System.Interrupt_Priority. If the check fails, Program_Error is raised.

12/3 {*8652/0068*} {*AI95-00121-01*} {*AI05-0229-1*} When a protected object is finalized, for any of its procedures that are attached to interrupts, the handler is detached. If the handler was attached by a procedure in the Interrupts package or if no user handler was previously attached to the interrupt, the default treatment is restored. If the Attach_Handler aspect was specified and the most recently attached handler for the same interrupt is the same as the one that was attached at the time the protected object was initialized, the previous handler is restored.

12.a/3 **Discussion:** {*8652/0068*} {*AI95-00121-01*} {*AI95-00303-01*} {*AI05-0229-1*} If all protected objects for interrupt handlers are declared at the library level, the finalization discussed above occurs only as part of the finalization of all library-level packages in a partition. However, objects of a protected type containing procedures with an Attach_Handler aspect specified need not be at the library level. Thus, an implementation needs to be able to restore handlers during the execution of the program. (An object with an Interrupt_Handler aspect also need not be at the library level, but such a handler cannot be attached to an interrupt using the Interrupts package.)

13 When a handler is attached to an interrupt, the interrupt is blocked [(subject to the Implementation Permission in C.3)] during the execution of every protected action on the protected object containing the handler.

13.1/5 {*AI12-0252-1*} If restriction No_Dynamic_Attachment is in effect, then a check is made that the interrupt identified by an Attach_Handler aspect does not appear in any previously elaborated Attach_Handler aspect; Program_Error is raised if this check fails.

13.a/5 **Reason:** When No_Dynamic_Attachment is in effect, it is not possible to call any previous handler. Therefore, the only possibility is to replace the original handler, rendering it ineffective. Having an unused handler in a program is likely a bug, so we require an exception to be raised.

Erroneous Execution

14 If the Ceiling_Locking policy (see D.3) is in effect and an interrupt is delivered to a handler, and the interrupt hardware priority is higher than the ceiling priority of the corresponding protected object, the execution of the program is erroneous.

14.1/3 {*8652/0068*} {*AI95-00121-01*} {*AI05-0229-1*} If the handlers for a given interrupt attached via aspect Attach_Handler are not attached and detached in a stack-like (LIFO) order, program execution is erroneous. In particular, when a protected object is finalized, the execution is erroneous if any of the procedures of the protected object are attached to interrupts via aspect Attach_Handler and the most recently attached handler for the same interrupt is not the same as the one that was attached at the time the protected object was initialized.

14.a/3 **Discussion:** {*8652/0068*} {*AI95-00121-01*} {*AI05-0229-1*} This simplifies implementation of the Attach_Handler aspect by not requiring a check that the current handler is the same as the one attached by the initialization of a protected object.

Metrics

15 The following metric shall be documented by the implementation:

16/2 • {*AI95-00434-01*} The worst-case overhead for an interrupt handler that is a parameterless protected procedure, in clock cycles. This is the execution time not directly attributable to the handler procedure or the interrupted execution. It is estimated as C – (A+B), where A is how long it takes to complete a given sequence of instructions without any interrupt, B is how long it takes to complete a normal call to a given protected procedure, and C is how long it takes to complete

the same sequence of instructions when it is interrupted by one execution of the same procedure called via an interrupt.

Implementation Note: The instruction sequence and interrupt handler used to measure interrupt handling overhead should be chosen so as to maximize the execution time cost due to cache misses. For example, if the processor has cache memory and the activity of an interrupt handler could invalidate the contents of cache memory, the handler should be written such that it invalidates all of the cache memory. 16.a

Documentation Requirement: The metrics for interrupt handlers. 16.b/2

Implementation Permissions

{*AI05-0229-1*} When the aspects Attach_Handler or Interrupt_Handler are specified for a protected procedure, the implementation is allowed to impose implementation-defined restrictions on the corresponding protected_type_declaration and protected_body. 17/3

Ramification: The restrictions may be on the constructs that are allowed within them, and on ordinary calls (i.e. not via interrupts) on protected operations in these protected objects. 17.a

Implementation defined: Any restrictions on a protected procedure or its containing type when an aspect Attach_handler or Interrupt_Handler is specified. 17.b/3

An implementation may use a different mechanism for invoking a protected procedure in response to a hardware interrupt than is used for a call to that protected procedure from a task. 18

Discussion: This is despite the fact that the priority of an interrupt handler (see D.1) is modeled after a hardware task calling the handler. 18.a

{*AI05-0229-1*} Notwithstanding what this subclause says elsewhere, the Attach_Handler and Interrupt_Handler aspects are allowed to be used for other, implementation defined, forms of interrupt handlers. 19/3

Ramification: {*AI05-0229-1*} For example, if an implementation wishes to allow interrupt handlers to have parameters, it is allowed to do so via these aspects; it need not invent implementation-defined aspects for the purpose. 19.a/3

Implementation defined: Any other forms of interrupt handler supported by the Attach_Handler and Interrupt_Handler aspects. 19.b/3

Implementation Advice

Whenever possible, the implementation should allow interrupt handlers to be called directly by the hardware. 20

Implementation Advice: Interrupt handlers should be called directly by the hardware. 20.a/2

Whenever practical, the implementation should detect violations of any implementation-defined restrictions before run time. 21

Implementation Advice: Violations of any implementation-defined restrictions on interrupt handlers should be detected before run time. 21.a/2

NOTE 1 {*AI05-0229-1*} {*AI12-0440-1*} The Attach_Handler aspect can provide static attachment of handlers to interrupts if the implementation supports preelaboration of protected objects. (See C.4.) 22/5

NOTE 2 {*AI95-00434-01*} {*AI12-0442-1*} For a protected object that has a (protected) procedure attached to an interrupt, the correct ceiling priority is at least as high as the highest processor priority at which that interrupt will ever be delivered. 23/5

NOTE 3 Protected procedures can also be attached dynamically to interrupts via operations declared in the predefined package Interrupts. 24

NOTE 4 An example of a possible implementation-defined restriction is disallowing the use of the standard storage pools within the body of a protected procedure that is an interrupt handler. 25

Incompatibilities With Ada 95

{*AI95-00253-01*} **Amendment Correction:** Corrected the wording so that the rules for the use of Attach_Handler and Interrupt_Handler are identical. This means that uses of pragma Interrupt_Handler outside of the target protected type or single protected object are now illegal. 25.a/2

Wording Changes from Ada 95

25.b/2 {*8652/0068*} {*AI95-00121-01*} **Corrigendum:** Clarified the meaning of "the previous handler" when finalizing protected objects containing interrupt handlers.

25.c/2 {*AI95-00303-01*} Dropped the requirement that an object of a type containing an Interrupt_Handler pragma must be declared at the library level. This was a generic contract model violation. This change is not an extension, as an attempt to attach such a handler with a routine in package Interrupts will fail an accessibility check anyway. Moreover, implementations can retain the rule as an implementation-defined restriction on the use of the type, as permitted by the Implementation Permissions above.

Extensions to Ada 2005

25.d/3 {*AI05-0229-1*} Aspects Interrupt_Handler and Attach_Handler are new; pragmas Interrupt_Handler and Attach_Handler are now obsolescent.

Wording Changes from Ada 2005

25.e/3 {*AI05-0033-1*} **Correction:** Added missing generic contract wording for the aspects Attach_Handler and Interrupt_Handler.

Inconsistencies With Ada 2012

25.f/5 {*AI12-0252-1*} **Correction:** Program_Error might be raised if two handlers are attached when restriction No_Dynamic_Attachment is in effect (including as part of the Ravenscar profile). Original Ada 2012 would have just ignored the first handler. This is almost certainly a bug rather than an intended result.

C.3.2 The Package Interrupts

Static Semantics

1 The following language-defined packages exist:

2/5
```
{AI05-0167-1} {AI12-0241-1} {AI12-0302-1} with System;
with System.Multiprocessors;
package Ada.Interrupts
   with Nonblocking, Global => in out synchronized is
   type Interrupt_Id is implementation-defined;
   type Parameterless_Handler is
      access protected procedure
      with Nonblocking => False;
```

3/1 *This paragraph was deleted.*

4
```
   function Is_Reserved (Interrupt : Interrupt_Id)
      return Boolean;
```

5
```
   function Is_Attached (Interrupt : Interrupt_Id)
      return Boolean;
```

6
```
   function Current_Handler (Interrupt : Interrupt_Id)
      return Parameterless_Handler;
```

7
```
   procedure Attach_Handler
      (New_Handler : in Parameterless_Handler;
       Interrupt   : in Interrupt_Id);
```

8
```
   procedure Exchange_Handler
      (Old_Handler : out Parameterless_Handler;
       New_Handler : in Parameterless_Handler;
       Interrupt   : in Interrupt_Id);
```

9
```
   procedure Detach_Handler
      (Interrupt : in Interrupt_Id);
```

10
```
   function Reference (Interrupt : Interrupt_Id)
      return System.Address;
```

10.1/3
```
   {AI05-0167-1}    function Get_CPU (Interrupt : Interrupt_Id)
      return System.Multiprocessors.CPU_Range;
```

```
private                                                                    11
   ... -- not specified by the language
end Ada.Interrupts;
```

```
{AI12-0302-1} package Ada.Interrupts.Names                                 12/5
   with Nonblocking, Global => null is
   implementation-defined : constant Interrupt_Id :=
      implementation-defined;
         . . .
   implementation-defined : constant Interrupt_Id :=
      implementation-defined;
end Ada.Interrupts.Names;
```

Dynamic Semantics

The Interrupt_Id type is an implementation-defined discrete type used to identify interrupts. 13

The Is_Reserved function returns True if and only if the specified interrupt is reserved. 14

The Is_Attached function returns True if and only if a user-specified interrupt handler is attached to the interrupt. 15

{*8652/0069*} {*AI95-00166-01*} The Current_Handler function returns a value that represents the attached handler of the interrupt. If no user-defined handler is attached to the interrupt, Current_Handler returns **null**. 16/1

{*AI05-0229-1*} The Attach_Handler procedure attaches the specified handler to the interrupt, overriding any existing treatment (including a user handler) in effect for that interrupt. If New_Handler is **null**, the default treatment is restored. If New_Handler designates a protected procedure for which the aspect Interrupt_Handler is False, Program_Error is raised. In this case, the operation does not modify the existing interrupt treatment. 17/3

{*8652/0069*} {*AI95-00166-01*} The Exchange_Handler procedure operates in the same manner as Attach_Handler with the addition that the value returned in Old_Handler designates the previous treatment for the specified interrupt. If the previous treatment is not a user-defined handler, **null** is returned. 18/1

Ramification: Calling Attach_Handler or Exchange_Handler with this value for New_Handler restores the previous handler. 18.a

{*8652/0069*} {*AI95-00166-01*} If the application uses only parameterless procedures as handlers (other types of handlers may be provided by the implementation, but are not required by the standard), then if Old_Handler is not **null**, it may be called to execute the previous handler. This provides a way to cascade application interrupt handlers. However, the default handler cannot be cascaded this way (Old_Handler must be **null** for the default handler). 18.a.1/1

The Detach_Handler procedure restores the default treatment for the specified interrupt. 19

For all operations defined in this package that take a parameter of type Interrupt_Id, with the exception of Is_Reserved and Reference, a check is made that the specified interrupt is not reserved. Program_Error is raised if this check fails. 20

{*AI05-0229-1*} If, by using the Attach_Handler, Detach_Handler, or Exchange_Handler procedures, an attempt is made to detach a handler that was attached statically (using the aspect Attach_Handler), the handler is not detached and Program_Error is raised. 21/3

{*AI95-00434-01*} The Reference function returns a value of type System.Address that can be used to attach a task entry via an address clause (see J.7.1) to the interrupt specified by Interrupt. This function raises Program_Error if attaching task entries to interrupts (or to this particular interrupt) is not supported. 22/2

{*AI05-0153-3*} The function Get_CPU returns the processor on which the handler for Interrupt is executed. If the handler can execute on more than one processor the value System.Multiprocessors.Not_A_Specific_CPU is returned. 22.1/3

Implementation Requirements

23 At no time during attachment or exchange of handlers shall the current handler of the corresponding interrupt be undefined.

Documentation Requirements

24/5 {*AI95-00434-01*} {*AI05-0229-1*} {*AI12-0320-1*} {*AI12-0444-1*} The implementation shall document, when the Ceiling_Locking policy (see D.3) is in effect, the default ceiling priority assigned to a protected object that contains a protected procedure that specifies either the Attach_Handler or Interrupt_Handler aspects, but does not specify the Interrupt_Priority aspect. [This default can be different for different interrupts.]

24.a.1/3 **Documentation Requirement:** If the Ceiling_Locking policy is in effect, the default ceiling priority for a protected object that specifies an interrupt handler aspect.

Implementation Advice

25 If implementation-defined forms of interrupt handler procedures are supported, such as protected procedures with parameters, then for each such form of a handler, a type analogous to Parameterless_Handler should be specified in a child package of Interrupts, with the same operations as in the predefined package Interrupts.

25.a/2 **Implementation Advice:** If implementation-defined forms of interrupt handler procedures are supported, then for each such form of a handler, a type analogous to Parameterless_Handler should be specified in a child package of Interrupts, with the same operations as in the predefined package Interrupts.

26 NOTE The package Interrupts.Names contains implementation-defined names (and constant values) for the interrupts that are supported by the implementation.

Examples

27 *Example of interrupt handlers:*

28/5
```
{AI05-0229-1} {AI12-0178-1} Device_Priority : constant
  array (Ada.Interrupts.Interrupt_Id range 1..5) of
    System.Interrupt_Priority := ( ... );
protected type Device_Interface
  (Int_Id : Ada.Interrupts.Interrupt_Id)
     with Interrupt_Priority => Device_Priority(Int_Id) is
  procedure Handler
     with Attach_Handler => Int_Id;
  ...
end Device_Interface;
  ...
Device_1_Driver : Device_Interface(1);
  ...
Device_5_Driver : Device_Interface(5);
  ...
```

Wording Changes from Ada 95

28.a/2 {*8652/0069*} {*AI95-00166-01*} **Corrigendum:** Clarified that the value returned by Current_Handler and Exchange_Handler for the default treatment is null.

Incompatibilities With Ada 2005

28.b/3 {*AI05-0167-1*} Function Get_CPU is added to Interrupts. If Interrupts is referenced in a use_clause, and an entity *E* with a defining_identifier of Get_CPU is defined in a package that is also referenced in a use_clause, the entity *E* may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur.

C.4 Preelaboration Requirements

{*AI05-0299-1*} {*AI12-0417-1*} [This subclause specifies additional implementation and documentation requirements for the Preelaborate aspect (see 10.2.1).] 1/5

Implementation Requirements

The implementation shall not incur any run-time overhead for the elaboration checks of subprograms and protected_bodies declared in preelaborated library units. 2

The implementation shall not execute any memory write operations after load time for the elaboration of constant objects declared immediately within the declarative region of a preelaborated library package, so long as the subtype and initial expression (or default initial expressions if initialized by default) of the object_declaration satisfy the following restrictions. The meaning of *load time* is implementation defined. 3

Discussion: On systems where the image of the partition is initially copied from disk to RAM, or from ROM to RAM, prior to starting execution of the partition, the intention is that "load time" consist of this initial copying step. On other systems, load time and run time might actually be interspersed. 3.a

- Any subtype_mark denotes a statically constrained subtype, with statically constrained subcomponents, if any; 4
- {*AI95-00161-01*} no subtype_mark denotes a controlled type, a private type, a private extension, a generic formal private type, a generic formal derived type, or a descendant of such a type; 4.1/2

  Reason: For an implementation that uses the registration method of finalization, a controlled object will require some code executed to register the object at the appropriate point. The other types are those that *might* have a controlled component. None of these types were allowed in preelaborated units in Ada 95. These types are covered by the Implementation Advice, of course, so they should still execute as little code as possible. 4.a.1/2
- any constraint is a static constraint; 5
- any allocator is for an access-to-constant type; 6
- any uses of predefined operators appear only within static expressions; 7
- any primaries that are names, other than attribute_references for the Access or Address attributes, appear only within static expressions; 8

  Ramification: This cuts out attribute_references that are not static, except for Access and Address. 8.a
- {*AI12-0368-1*} any name that is not part of a static expression is an expanded name or direct_name that statically names some entity; 9/5

  Ramification: {*AI12-0368-1*} This cuts out function_calls and type_conversions that are not static, including calls on attribute functions like 'Image and 'Value. We do allow components if those components don't require any evaluation or checks. 9.a/5
- any discrete_choice of an array_aggregate is static; 10
- no language-defined check associated with the elaboration of the object_declaration can fail. 11

  Reason: {*AI95-00114-01*} The intent is that aggregates all of whose scalar subcomponents are static and all of whose access subcomponents are **null**, allocators for access-to-constant types, or X'Access, will be supported with no run-time code generated. 11.a/2

Documentation Requirements

The implementation shall document any circumstances under which the elaboration of a preelaborated package causes code to be executed at run time. 12

Documentation Requirement: Any circumstances when the elaboration of a preelaborated package causes code to be executed. 12.a/2

13 The implementation shall document whether the method used for initialization of preelaborated variables allows a partition to be restarted without reloading.

13.a.1/2 **Documentation Requirement:** Whether a partition can be restarted without reloading.

13.a/2 *This paragraph was deleted.*

13.b/2 **Discussion:** {*AI95-00114-01*} This covers the issue of the run-time system itself being restartable, so that need not be a separate Documentation Requirement.

Implementation Advice

14 It is recommended that preelaborated packages be implemented in such a way that there should be little or no code executed at run time for the elaboration of entities not already covered by the Implementation Requirements.

14.a/2 **Implementation Advice:** Preelaborated packages should be implemented such that little or no code is executed at run time for the elaboration of entities.

Wording Changes from Ada 95

14.b/2 {*AI95-00161-01*} Added wording to exclude the additional kinds of types allowed in preelaborated units from the Implementation Requirements.

Wording Changes from Ada 2012

14.c/5 {*AI12-0368-1*} Added wording to allow components so long as no evaluation or checks are required for the reference.

C.5 Aspect Discard_Names

1/4 {*AI12-0072-1*} [Specifying the aspect Discard_Names can be used to request a reduction in storage used for the names of entities with runtime name text.]

Static Semantics

1.1/4 {*AI12-0072-1*} An entity with *runtime name text* is a nonderived enumeration first subtype, a tagged first subtype, or an exception.

1.2/4 {*AI12-0072-1*} For an entity with runtime name text, the following language-defined representation aspect may be specified:

1.3/4 Discard_Names

The type of aspect Discard_Names is Boolean. If directly specified, the aspect_definition shall be a static expression. If not specified (including by inheritance), the aspect is False.

1.a.1/4 **Aspect Description for Discard_Names:** Requests a reduction in storage for names associated with an entity.

Syntax

2 The form of a pragma Discard_Names is as follows:

3 **pragma** Discard_Names[([On =>] local_name)];

4 A pragma Discard_Names is allowed only immediately within a declarative_part, immediately within a package_specification, or as a configuration pragma.

Legality Rules

5/4 {*AI12-0072-1*} The local_name (if present) shall denote an entity with runtime name text. The pragma specifies that the aspect Discard_Names for the type or exception has the value True. Without a local_name, the pragma specifies that all entities with runtime name text declared after the pragma, within the same declarative region have the value True for aspect Discard_Names. Alternatively, the pragma can be used as a configuration pragma. If the configuration pragma Discard_Names applies to a

compilation unit, all entities with runtime name text declared in the compilation unit have the value True for the aspect Discard_Names.

Ramification: {*AI12-0072-1*} If the aspect is specified for a type, then it is inherited by all descendants of the type. The aspect cannot be specified as False on a derived type (because specifying the aspect is not allowed on derived enumeration types, and by rule applying to all aspects for other types (see 13.1.1)). 5.a/4

Static Semantics

If a local_name is given, then a pragma Discard_Names is a representation pragma. 6

This paragraph was deleted. {*AI05-0229-1*} {*AI12-0072-1*} 6.a/4

{*AI95-00285-01*} {*AI95-00400-01*} {*AI12-0072-1*} If the aspect Discard_Names is True for an enumeration type, then the semantics of the Wide_Wide_Image and Wide_Wide_Value attributes are implementation defined for that type[; the semantics of Image, Wide_Image, Value, and Wide_Value are still defined in terms of Wide_Wide_Image and Wide_Wide_Value]. In addition, the semantics of Text_IO.Enumeration_IO are implementation defined. If the aspect Discard_Names is True for a tagged type, then the semantics of the Tags.Wide_Wide_Expanded_Name function are implementation defined for that type[; the semantics of Tags.Expanded_Name and Tags.Wide_Expanded_Name are still defined in terms of Tags.Wide_Wide_Expanded_Name]. If the aspect Discard_Names is True for an exception, then the semantics of the Exceptions.Wide_Wide_Exception_Name function are implementation defined for that exception[; the semantics of Exceptions.Exception_Name and Exceptions.Wide_Exception_Name are still defined in terms of Exceptions.Wide_Wide_Exception_Name]. 7/4

Implementation defined: The semantics of some attributes and functions of an entity for which aspect Discard_Names is True. 7.a/4

Ramification: The Width attribute is still defined in terms of Image. 7.b

{*AI95-00285-01*} {*AI12-0072-1*} The semantics of S'Wide_Wide_Image and S'Wide_Wide_Value are implementation defined for any subtype of an enumeration type for which the aspect is True. (The pragma, if used, actually names the first subtype, of course.) 7.c/4

Implementation Advice

{*AI12-0072-1*} If the aspect Discard_Names is True for an entity, then the implementation should reduce the amount of storage used for storing names associated with that entity. 8/4

Implementation Advice: If aspect Discard_Names is True for an entity, then the amount of storage used for storing names associated with that entity should be reduced. 8.a/4

Reason: A typical implementation of the Image attribute for enumeration types is to store a table containing the names of all the enumeration literals. Aspect Discard_Names allows the implementation to avoid storing such a table without having to prove that the Image attribute is never used (which can be difficult in the presence of separate compilation). 8.b

We did not specify the semantics of the Image attribute when aspect Discard_Names is True because different semantics might be desirable in different situations. In some cases, it might make sense to use the Image attribute to print out a useful value that can be used to identify the entity given information in compiler-generated listings. In other cases, it might make sense to get an error at compile time or at run time. In cases where memory is plentiful, the simplest implementation makes sense: ignore the aspect. Implementations that are capable of avoiding the extra storage in cases where the Image attribute is never used might also wish to ignore the aspect. 8.c

The same applies to the Tags.Expanded_Name and Exceptions.Exception_Name functions. 8.d

Wording Changes from Ada 95

{*AI95-00285-01*} {*AI95-00400-01*} Updated the wording to reflect that the double wide image and value functions are now the master versions that the others are defined from. 8.e/2

Wording Changes from Ada 2012

{*AI12-0072-1*} **Corrigendum:** Defined the pragma in terms of the aspect Discard_Names, and added a missing definition of the meaning of the configuration pragma. This is not intended to make any semantic change (Ada 2012 has an aspect Discard_Names defined via blanket rules for representation pragmas in 13.1 and 13.1.1), just to clarify the meaning. 8.f/4

C.6 Shared Variable Control

1/3 {*AI05-0229-1*} {*AI05-0299-1*} [This subclause defines representation aspects that control the use of shared variables.]

Paragraphs 2 through 6 were moved to Annex J, "Obsolescent Features".

Static Semantics

6.1/5 {*AI05-0229-1*} {*AI12-0282-1*} For an object_declaration, a component_declaration, a full_type_declaration, or a formal_complete_type_declaration, the following representation aspects may be specified:

6.2/3 Atomic The type of aspect Atomic is Boolean.

6.a/3 **Aspect Description for Atomic:** Declare that a type, object, or component is atomic.

6.3/3 Independent The type of aspect Independent is Boolean.

6.b/3 **Aspect Description for Independent:** Declare that a type, object, or component is independently addressable.

6.4/3 Volatile The type of aspect Volatile is Boolean.

6.c/3 **Aspect Description for Volatile:** Declare that a type, object, or component is volatile.

6.5/5 {*AI12-0363-1*} Full_Access_Only
The type of aspect Full_Access_Only is Boolean.

6.c.1/5 **Aspect Description for Full_Access_Only:** Declare that a volatile type, object, or component is full access.

6.6/5 {*AI05-0229-1*} {*AI12-0282-1*} For a full_type_declaration of an array type, an object_declaration for an object of an anonymous array type, or the formal_complete_type_declaration of a formal array type, the following representation aspects may be specified:

6.7/3 Atomic_Components
The type of aspect Atomic_Components is Boolean.

6.d/3 **Aspect Description for Atomic_Components:** Declare that the components of an array type or object are atomic.

6.8/3 Volatile_Components
The type of aspect Volatile_Components is Boolean.

6.e/3 **Aspect Description for Volatile_Components:** Declare that the components of an array type or object are volatile.

6.9/5 {*AI05-0229-1*} {*AI12-0282-1*} For a full_type_declaration of a composite type, an object_declaration for an object of an anonymous composite type, or the formal_complete_type_declaration of a formal composite type, the following representation aspect may be specified:

6.10/3 Independent_Components
The type of aspect Independent_Components is Boolean.

6.f/3 **Aspect Description for Independent_Components:** Declare that the components of an array or record type, or an array object, are independently addressable.

6.11/5 {*AI05-0229-1*} {*AI12-0363-1*} If any of these aspects are directly specified, the aspect_definition shall be a static expression. If not specified for a type (including by inheritance), the Atomic, Atomic_Components, and Full_Access_Only aspects are False. If any of these aspects are specified True for a type, then the corresponding aspect is True for all objects of the type. If the Atomic aspect is specified True, then the aspects Volatile, Independent, and Volatile_Component (if defined) are True; if the Atomic_Components aspect is specified True, then the aspects Volatile, Volatile_Components, and Independent_Components are True. If the Volatile aspect is specified True, then the Volatile_Components aspect (if defined) is True, and vice versa. When not determined by one of the

other aspects, or for an object by its type, the Volatile, Volatile_Components, Independent, and Independent_Components aspects are False.

Ramification: {*AI12-0363-1*} Aspects Volatile and Volatile_Components (when defined) are equivalent. We provide the Volatile_Components aspect only to give symmetry with Atomic_Components and Independent_Components aspects. 6.g/5

{*AI95-00272-01*} {*AI05-0229-1*} An *atomic* type is one for which the aspect Atomic is True. An *atomic* object (including a component) is one for which the aspect Atomic is True, or a component of an array for which the aspect Atomic_Components is True for the associated type, or any object of an atomic type, other than objects obtained by evaluating a slice. 7/3

Ramification: {*AI95-00272-01*} A slice of an atomic array object is not itself atomic. That's necessary as executing a read or write of a dynamic number of components in a single instruction is not possible on many targets. 7.a/2

{*AI05-0229-1*} A *volatile* type is one for which the aspect Volatile is True. A *volatile* object (including a component) is one for which the aspect Volatile is True, or a component of an array for which the aspect Volatile_Components is True for the associated type, or any object of a volatile type. In addition, every atomic type or object is also defined to be volatile. Finally, if an object is volatile, then so are all of its subcomponents [(the same does not apply to atomic)]. 8/3

{*AI05-0009-1*} {*AI05-0229-1*} {*AI12-0001-1*} When True, the aspects Independent and Independent_Components *specify as independently addressable* the named object or component(s), or in the case of a type, all objects or components of that type. All atomic objects and aliased objects are considered to be specified as independently addressable. 8.1/4

Ramification: If the compiler cannot guarantee that an object (including a component) for which aspect Independent or aspect Independent_Components is True is independently addressable from any other nonoverlapping object, then the aspect specification must be rejected. 8.a/3

Similarly, an atomic object (including atomic components) is always independently addressable from any other nonoverlapping object. Any representation item which would prevent this from being true should be rejected, notwithstanding what this Standard says elsewhere (specifically, in the Recommended Level of Support). 8.b/3

{*AI12-0363-1*} The Full_Access_Only aspect shall not be specified unless the associated type or object is volatile [(or atomic)]. A *full access* type is any atomic type, or a volatile type for which the aspect Full_Access_Only is True. A *full access* object (including a component) is any atomic object, or a volatile object for which the aspect Full_Access_Only is True for the object[or its type]. A Full_Access_Only aspect is illegal if any subcomponent of the object or type is a full access object or is of a generic formal type. 8.2/5

Ramification: {*AI12-0363-1*} This last rule breaks privacy, but that is considered OK for representation clauses when there is no clear alternative. Note that atomic objects may be nested, so long as the outer atomic object does not have the Full_Access_Only aspect True. 8.c/5

Reason: {*AI12-0363-1*} We disallow subcomponents of a generic formal type in a Full_Access_Only object or type as the actual to a formal type can be a full access type. We could have had a less restrictive rule, but such a use is unlikely as full access only objects are intended to be used to access memory-mapped devices with access restrictions, and those will need a concrete mapping not possible for generic formal types. 8.d/5

Paragraph 9 was moved to Annex J, "Obsolescent Features".

Legality Rules

{*AI05-0229-1*} If aspect Independent_Components is specified for a full_type_declaration, the declaration shall be that of an array or record type. 9.1/3

{*AI05-0229-1*} {*AI12-0001-1*} It is illegal to specify either of the aspects Atomic or Atomic_Components to have the value True for an object or type if the implementation cannot support the indivisible and independent reads and updates required by the aspect (see below). 10/4

11/4 {*AI12-0001-1*} It is illegal to specify the Size attribute of an atomic object, the Component_Size attribute for an array type with atomic components, or the layout attributes of an atomic component, in a way that prevents the implementation from performing the required indivisible and independent reads and updates.

12/5 {*AI05-0142-4*} {*AI05-0218-1*} {*AI12-0282-1*} {*AI12-0363-1*} If an atomic object is passed as a parameter, then the formal parameter shall either have an atomic type or allow pass by copy. If an atomic object is used as an actual for a generic formal object of mode **in out**, then the type of the generic formal object shall be atomic. If the prefix of an attribute_reference for an Access attribute denotes an atomic object [(including a component)], then the designated type of the resulting access type shall be atomic. Corresponding rules apply to volatile objects and to full access objects.

12.a/3 **Ramification:** {*AI05-0142-4*} A formal parameter allows pass by copy if it is not **aliased** and it is of a type that allows pass by copy (that is, is not a by-reference type).

12.1/5 {*AI12-0128-1*} {*AI12-0363-1*} If a nonatomic subcomponent of a full access object is passed as an actual parameter in a call then the formal parameter shall allow pass by copy (and, at run time, the parameter shall be passed by copy). A nonatomic subcomponent of a full access object shall not be used as an actual for a generic formal of mode **in out**. The prefix of an attribute_reference for an Access attribute shall not denote a nonatomic subcomponent of a full access object.

12.2/5 {*AI05-0218-1*} {*AI12-0282-1*} {*AI12-0363-1*} If the Atomic, Atomic_Components, Volatile, Volatile_Components, Independent, Independent_Components, or Full_Access_Only aspect is True for a generic formal type, then that aspect shall be True for the actual type. If an atomic type is used as an actual for a generic formal derived type, then the ancestor of the formal type shall be atomic. A corresponding rule applies to volatile types and similarly to full access types.

12.3/5 {*AI12-0363-1*} If a type with volatile components is used as an actual for a generic formal array type, then the components of the formal type shall be volatile. Furthermore, if the actual type has atomic components and the formal array type has aliased components, then the components of the formal array type shall also be atomic. A corresponding rule applies when the actual type has volatile full access components.

12.b/5 **Reason:** {*AI12-0363-1*} The limitations on formal array types are separate for volatile and atomic because of the fact that only volatility is carried down to all subcomponents of a volatile object, while atomicity is not. The goal of both limitations is that we don't want 'Access for an access type to produce a value that designates an object whose atomicity and volatility don't agree with that of the designated type of the access type. The above rules ensure that the generic “sees” the relevant volatility and atomicity.

13/3 {*AI05-0229-1*} If an aspect Volatile, Volatile_Components, Atomic, or Atomic_Components is directly specified to have the value True for a stand-alone constant object, then the aspect Import shall also be specified as True for it.

13.a **Ramification:** Hence, no initialization expression is allowed for such a constant. Note that a constant that is atomic or volatile because of its type is allowed.

13.b **Reason:** Stand-alone constants that are explicitly specified as Atomic or Volatile only make sense if they are being manipulated outside the Ada program. From the Ada perspective the object is read-only. Nevertheless, if imported and atomic or volatile, the implementation should presume it might be altered externally. For an imported stand-alone constant that is not atomic or volatile, the implementation can assume that it will not be altered.

13.c/3 **To be honest:** {*AI05-0218-1*} Volatile_Components and Atomic_Components actually are aspects of the anonymous array type; this rule only applies when the aspect is specified directly on the constant object and not when the (named) array type has the aspect.

13.1/3 {*AI05-0009-1*} {*AI05-0229-1*} It is illegal to specify the aspect Independent or Independent_Components as True for a component, object or type if the implementation cannot provide the independent addressability required by the aspect (see 9.10).

{*AI05-0009-1*} {*AI05-0229-1*} It is illegal to specify a representation aspect for a component, object or type for which the aspect Independent or Independent_Components is True, in a way that prevents the implementation from providing the independent addressability required by the aspect. 13.2/3

Paragraph 14 was moved to Annex J, "Obsolescent Features".

Dynamic Semantics

For an atomic object (including an atomic component) all reads and updates of the object as a whole are indivisible. 15

{*AI05-0117-1*} {*AI05-0275-1*} All tasks of the program (on all processors) that read or update volatile variables see the same order of updates to the variables. A use of an atomic variable or other mechanism may be necessary to avoid erroneous execution and to ensure that access to nonatomic volatile variables is sequential (see 9.10). 16/3

Implementation Note: {*AI05-0117-1*} {*AI05-0275-1*} To ensure this, on a multiprocessor, any read or update of an atomic object may require the use of an appropriate memory barrier. 16.a/3

Discussion: {*AI05-0275-1*} From 9.10 it follows that (in non-erroneous programs) accesses to variables, including those shared by multiple tasks, are always sequential. This guarantees that no task will ever see partial updates of any variable. For volatile variables (including atomic variables), the above rule additionally specifies that all tasks see the same order of updates. 16.b/3

{*AI05-0275-1*} If for a shared variable *X*, a read of *X* occurs sequentially after an update of *X*, then the read will return the updated value if *X* is volatile or atomic, but may or or may not return the updated value if *X* is nonvolatile. For nonvolatile accesses, a signaling action is needed in order to share the updated value. 16.c/3

{*AI05-0275-1*} Because accesses to the same atomic variable by different tasks establish a sequential order between the actions of those tasks, implementations may be required to emit memory barriers around such updates or use atomic instructions that imply such barriers. 16.d/3

Two actions are sequential (see 9.10) if each is the read or update of the same atomic object. 17

If a type is atomic or volatile and it is not a by-copy type, then the type is defined to be a by-reference type. If any subcomponent of a type is atomic or volatile, then the type is defined to be a by-reference type. 18

If an actual parameter is atomic or volatile, and the corresponding formal parameter is not, then the parameter is passed by copy. 19

Implementation Note: Note that in the case where such a parameter is normally passed by reference, a copy of the actual will have to be produced at the call-site, and a pointer to the copy passed to the formal parameter. If the actual is atomic, any copying has to use indivisible read on the way in, and indivisible write on the way out. 19.a

Reason: It has to be known at compile time whether an atomic or a volatile parameter is to be passed by copy or by reference. For some types, it is unspecified whether parameters are passed by copy or by reference. The above rules further specify the parameter passing rules involving atomic and volatile types and objects. 19.b

{*AI12-0128-1*} {*AI12-0347-1*} All reads of or writes to any nonatomic subcomponent of a full access object are performed by reading and/or writing all of the nearest enclosing full access object. 19.1/5

Implementation Note: {*AI12-0005-1*} {*AI12-0128-1*} } For example, if a 32-bit record object has four nonatomic components, each occupying one byte, then an assignment to one of those components might normally be implemented on some target machines via some sort of store_byte instruction; if the record object is an atomic full access object then instead a 32-bit read-modify-write must be performed. That read-modify-write need not be atomic, although the read and the write must each separately be atomic. Note that it doesn't matter whether the store_byte instruction would have executed atomically. This rule is needed in some cases for memory-mapped device registers. 19.c/5

Discussion: The atomic reads and writes associated with accesses to nonatomic components of a full access object that is atomic are normal atomic operations — all of the rules that apply to other atomic operations apply to these as well. In particular, these atomic reads and writes are sequential if they apply to the same object. 19.d/5

Implementation Requirements

20/5 {*AI12-0128-1*} {*AI12-0439-1*} The external effect of a program (see 1.1.3) is defined to include each read and update of a volatile or atomic object. The implementation shall not generate any memory reads or updates of atomic or volatile objects other than those specified by the program. However, there may be target-dependent cases where reading or writing a volatile but nonatomic object (typically a component) necessarily involves reading and/or writing neighboring storage, and that neighboring storage can overlap a volatile object.

20.a **Discussion:** The presumption is that volatile or atomic objects might reside in an "active" part of the address space where each read has a potential side effect, and at the very least might deliver a different value.

20.b The rule above and the definition of external effect are intended to prevent (at least) the following incorrect optimizations, where V is a volatile variable:

20.c - X:= V; Y:=V; cannot be allowed to be translated as Y:=V; X:=V;

20.d - Deleting redundant loads: X:= V; X:= V; shall read the value of V from memory twice.

20.e - Deleting redundant stores: V:= X; V:= X; shall write into V twice.

20.f - Extra stores: V:= X+Y; should not translate to something like V:= X; V:= V+Y;

20.g - Extra loads: X:= V; Y:= X+Z; X:=X+B; should not translate to something like Y:= V+Z; X:= V+B;

20.h - Reordering of loads from volatile variables: X:= V1; Y:= V2; (whether or not V1 = V2) should not translate to Y:= V2; X:= V1;

20.i - Reordering of stores to volatile variables: V1:= X; V2:= X; should not translate to V2:=X; V1:= X;

20.j/5 {*AI12-0128-1*} The part about "target-dependent cases" is intended to let compilers use a read-modify-write operation when a volatile component has a size that cannot be directly read or written with the available machine instructions. (For instance, writing a Boolean component with size 1 in a volatile packed array of Boolean requires a pre-read on most existing machines.)

21/4 *This paragraph was deleted.*{*AI05-0229-1*} {*AI12-0001-1*}

21.a/4 *This paragraph was deleted.*{*AI05-0009-1*} {*AI12-0001-1*}

Implementation Permissions

21.1/5 {*AI12-0282-1*} Within the body of an instance of a generic unit that has a formal type *T* that is not atomic and an actual type that is atomic, if an object *O* of type *T* is declared and explicitly specified as atomic, the implementation may introduce an additional copy on passing *O* to a subprogram with a parameter of type *T* that is normally passed by reference. A corresponding permission applies to volatile parameter passing.

Implementation Advice

22/5 {*AI95-00259-01*} {*AI12-0128-1*} A load or store of a volatile object whose size is a multiple of System.Storage_Unit and whose alignment is nonzero, should be implemented by accessing exactly the bits of the object and no others, except in the case of a volatile but nonatomic subcomponent of an atomic object.

22.a/2 **Implementation Advice:** A load or store of a volatile object whose size is a multiple of System.Storage_Unit and whose alignment is nonzero, should be implemented by accessing exactly the bits of the object and no others.

22.b/5 **Reason:** {*AI12-0128-1*} Since any object can be a volatile object, including packed array components and bit-mapped record components, we require the above only when it is reasonable to assume that the machine can avoid accessing bits outside of the object. The exception is needed so this advice doesn't conflict with other rules of this subclauase.

22.c/2 **Ramification:** This implies that the load or store of a volatile object that meets the above requirement should not be combined with that of any other object, nor should it access any bits not belonging to any other object. This means that the suitability of the implementation for memory-mapped I/O can be determined from its documentation, as any cases where the implementation does not follow Implementation Advice must be documented.

23/2 {*AI95-00259-01*} A load or store of an atomic object should, where possible, be implemented by a single load or store instruction.

Implementation Advice: A load or store of an atomic object should be implemented by a single load or store instruction. 23.a/2

NOTE 1 An imported volatile or atomic constant behaves as a constant (i.e. read-only) with respect to other parts of the Ada program, but can still be modified by an “external source”. 24

NOTE 2 {*AI12-0001-1*} Specifying the Pack aspect cannot override the effect of specifying an Atomic or Atomic_Components aspect. 25/4

NOTE 3 {*AI12-0128-1*} {*AI12-0440-1*} When mapping an Ada object to a memory-mapped hardware register, the Ada object can be declared atomic to ensure that the compiler will read and write exactly the bits of the register as specified in the source code and no others. 26/5

Discussion: This is especially important for a write-only hardware register, as in such a case a read-modify-write cycle will not work. The only time the language guarantees such a cycle will not happen is when writing an entire atomic object. If one wants to write individual components of a write-only hardware register (assuming the hardware supports that), those also need to be declared atomic. 26.a/5

Incompatibilities With Ada 83

Pragma Atomic replaces Ada 83's pragma Shared. The name “Shared” was confusing, because the pragma was not used to mark variables as shared. 26.b

Wording Changes from Ada 95

{*AI95-00259-01*} Added Implementation Advice to clarify the meaning of Atomic and Volatile in machine terms. The documentation that this advice applies will make the use of Ada implementations more predictable for low-level (such as device register) programming. 26.c/2

{*AI95-00272-01*} Added wording to clarify that a slice of an object of an atomic type is not atomic, just like a component of an atomic type is not (necessarily) atomic. 26.d/2

Incompatibilities With Ada 2005

{*AI05-0218-1*} **Correction:** Plugged a hole involving volatile components of formal types when the formal type's component has a nonvolatile type. This was done by making certain actual types illegal for formal derived and formal array types; these types were allowed for Ada 95 and Ada 2005. 26.e/3

Extensions to Ada 2005

{*AI05-0009-1*} {*AI05-0229-1*} Aspects Independent and Independent_Components are new; they eliminate ambiguity about independent addressability. 26.f/3

{*AI05-0229-1*} Aspects Atomic, Atomic_Components, Volatile, and Volatile_Components are new; pragmas Atomic, Atomic_Components, Volatile, and Volatile_Components are now obsolescent. 26.g/3

Wording Changes from Ada 2005

{*AI05-0117-1*} {*AI05-0275-1*} Revised the definition of volatile to eliminate overspecification and simply focus on the root requirement (that all tasks see the same view of volatile objects). This is not an inconsistency; "memory" arguably includes on-chip caches so long as those are kept consistent. Moreover, it is difficult to imagine a program that could tell the difference. 26.h/3

{*AI05-0142-4*} Added wording to take explicitly aliased parameters (see 6.1) into account when determining the legality of parameter passing of volatile and atomic objects. 26.i/3

Inconsistencies With Ada 2012

{*AI12-0128-1*} Required that nonatomic components of a atomic object use a read-modify-write cycle, as well as clarifying that such a cycle is allowed for volatile objects that aren't exactly the size of a machine scalar. That can introduce a read-modify-write cycle where one was not used previously (for instance, if the components are exactly byte-sized on most machines); it is thought that this will more often fix bugs with access to hardware than it will cause them. If this is an issue, declaring the components themselves as atomic will restore the previous behavior. 26.j/5

Extensions to Ada 2012

{*AI12-0282-1*} These aspects now can be specified for generic formal types. 26.k/5

{*AI12-0363-1*} Aspect Full_Access_Only is new; it can be used to guarantee access to a complete device register for any operation even when the register is mapped to a number of components. 26.l/5

Wording Changes from Ada 2012

26.m/4 {*AI12-0001-1*} **Corrigendum:** Clarified that aliased objects are considered to be specified as independently addressable, and also eliminated an unnecessary rule.

C.6.1 The Package System.Atomic_Operations

1/5 {*AI12-0234-1*} The language-defined package System.Atomic_Operations is the parent of a set of child units that provide facilities for manipulating objects of atomic types and for supporting lock-free synchronization. The subprograms of this subsystem are Intrinsic subprograms (see 6.3.1) in order to provide convenient access to machine operations that can provide these capabilities if they are available in the target environment.

Static Semantics

2/5 {*AI12-0234-1*} The library package System.Atomic_Operations has the following declaration:

3/5
```
package System.Atomic_Operations
   with Pure, Nonblocking is
end System.Atomic_Operations;
```

4/5 {*AI12-0234-1*} System.Atomic_Operations serves as the parent of other language-defined library units that manipulate atomic objects; its declaration is empty.

5/5 {*AI12-0234-1*} A call to a subprogram is said to be *lock-free* if the subprogram is guaranteed to return from the call while keeping the processor of the logical thread of control busy for the duration of the call.

6/5 {*AI12-0234-1*} In each child package, a function Is_Lock_Free(...) is provided to check whether the operations of the child package can all be provided lock-free for a given object. Is_Lock_Free returns True if operations defined in the child package are lock-free when applied to the object denoted by Item, and Is_Lock_Free returns False otherwise.

Extensions to Ada 2012

6.a/5 {*AI12-0234-1*} This package is new.

C.6.2 The Package System.Atomic_Operations.Exchange

1/5 {*AI12-0234-1*} The language-defined generic package System.Atomic_Operations.Exchange provides the following operations:

2/5 - To atomically compare the value of two atomic objects, and update the first atomic object with a desired value if both objects were found to be equal, or otherwise update the second object with the value of the first object.

3/5 - To atomically update the value of an atomic object, and then return the value that the atomic object had just prior to the update.

Static Semantics

4/5 {*AI12-0234-1*} The generic library package System.Atomic_Operations.Exchange has the following declaration:

5/5
```
generic
   type Atomic_Type is private with Atomic;
package System.Atomic_Operations.Exchange
   with Pure, Nonblocking is
```

6/5
```
   function Atomic_Exchange (Item  : aliased in out Atomic_Type;
                             Value : Atomic_Type) return Atomic_Type
      with Convention => Intrinsic;
```

```
   function Atomic_Compare_And_Exchange                                    7/5
     (Item    : aliased in out Atomic_Type;
      Prior   : aliased in out Atomic_Type;
      Desired : Atomic_Type) return Boolean
      with Convention => Intrinsic;
   function Is_Lock_Free (Item : aliased Atomic_Type) return Boolean       8/5
      with Convention => Intrinsic;
end System.Atomic_Operations.Exchange;                                     9/5
```

{*AI12-0234-1*} Atomic_Exchange atomically assigns the value of Value to Item, and returns the previous value of Item. 10/5

{*AI12-0234-1*} Atomic_Compare_And_Exchange first evaluates the value of Prior. Atomic_Compare_And_Exchange then performs the following steps as part of a single indivisible operation: 11/5

- evaluates the value of Item; 12/5
- compares the value of Item with the value of Prior; 13/5
- if equal, assigns Item the value of Desired; 14/5
- otherwise, makes no change to the value of Item. 15/5

{*AI12-0234-1*} After these steps, if the value of Item and Prior did not match, Prior is assigned the original value of Item, and the function returns False. Otherwise, Prior is unaffected and the function returns True. 16/5

Examples

{*AI12-0234-1*} *Example of a spin lock using Atomic_Exchange:* 17/5

```
type Atomic_Boolean is new Boolean with Atomic;                            18/5
package Exchange is new
   Atomic_Operations.Exchange (Atomic_Type => Atomic_Boolean);
Lock : aliased Atomic_Boolean := False;                                    19/5
...                                                                        20/5
begin -- Some critical section, trying to get the lock:                    21/5
   -- Obtain the lock                                                      22/5
   while Exchange.Atomic_Exchange (Item => Lock, Value => True) loop
      null;
   end loop;
   ... -- Do stuff                                                         23/5
   Lock := False; -- Release the lock                                      24/5
end;
```

Extensions to Ada 2012

{*AI12-0234-1*} This package is new. 24.a/5

C.6.3 The Package System.Atomic_Operations.Test_and_Set

{*AI12-0321-1*} The language-defined package System.Atomic_Operations.Test_And_Set provides an operation to atomically set and clear an atomic flag object. 1/5

Static Semantics

2/5 {*AI12-0321-1*} The library package System.Atomic_Operations.Test_And_Set has the following declaration:

3/5
```
package System.Atomic_Operations.Test_And_Set
   with Pure, Nonblocking is
```

4/5
```
   type Test_And_Set_Flag is mod implementation-defined
      with Atomic, Default_Value => 0, Size => implementation-defined;
```

5/5
```
   function Atomic_Test_And_Set
     (Item : aliased in out Test_And_Set_Flag) return Boolean
      with Convention => Intrinsic;
```

6/5
```
   procedure Atomic_Clear
     (Item : aliased in out Test_And_Set_Flag)
      with Convention => Intrinsic;
```

7/5
```
   function Is_Lock_Free
     (Item : aliased Test_And_Set_Flag) return Boolean
      with Convention => Intrinsic;
```

8/5
```
end System.Atomic_Operations.Test_And_Set;
```

8.a/5 **Implementation defined:** The modulus and size of Test_and_Set_Flag.

9/5 {*AI12-0321-1*} Test_And_Set_Flag represents the state of an atomic flag object. An atomic flag object can either be considered to be set or cleared.

10/5 {*AI12-0321-1*} Atomic_Test_And_Set performs an atomic test-and-set operation on Item. Item is set to some implementation-defined nonzero value. The function returns True if the previous contents were nonzero, and otherwise returns False.

10.a/5 **Implementation defined:** The value used to represent the set value for Atomic_Test_and_Set.

11/5 {*AI12-0321-1*} Atomic_Clear performs an atomic clear operation on Item. After the operation, Item contains 0. This call should be used in conjunction with Atomic_Test_And_Set.

Extensions to Ada 2012

11.a/5 {*AI12-0321-1*} This package is new.

C.6.4 The Package System.Atomic_Operations.Integer_Arithmetic

1/5 {*AI12-0321-1*} {*AI12-0364-1*} The language-defined generic package System.Atomic_Operations.Integer_Arithmetic provides operations to perform arithmetic atomically on objects of integer types.

Static Semantics

2/5 {*AI12-0321-1*} {*AI12-0364-1*} The generic library package System.Atomic_Operations.Integer_Arithmetic has the following declaration:

3/5
```
generic
   type Atomic_Type is range <> with Atomic;
package System.Atomic_Operations.Integer_Arithmetic
   with Pure, Nonblocking is
```

4/5
```
   procedure Atomic_Add (Item  : aliased in out Atomic_Type;
                         Value : Atomic_Type)
      with Convention => Intrinsic;
```

5/5
```
   procedure Atomic_Subtract (Item  : aliased in out Atomic_Type;
                              Value : Atomic_Type)
      with Convention => Intrinsic;
```

```
   function Atomic_Fetch_And_Add                                                    6/5
     (Item  : aliased in out Atomic_Type;
      Value : Atomic_Type) return Atomic_Type
      with Convention => Intrinsic;

   function Atomic_Fetch_And_Subtract                                               7/5
     (Item  : aliased in out Atomic_Type;
      Value : Atomic_Type) return Atomic_Type
      with Convention => Intrinsic;

   function Is_Lock_Free (Item : aliased Atomic_Type) return Boolean                8/5
      with Convention => Intrinsic;

end System.Atomic_Operations.Integer_Arithmetic;                                    9/5
```

{*AI12-0321-1*} The operations of this package are defined as follows: 10/5

```
procedure Atomic_Add (Item  : aliased in out Atomic_Type;                           11/5
                      Value : Atomic_Type)
   with Convention => Intrinsic;
```

{*AI12-0321-1*} Atomically performs: `Item := Item + Value;` 12/5

```
procedure Atomic_Subtract (Item  : aliased in out Atomic_Type;                      13/5
                           Value : Atomic_Type)
   with Convention => Intrinsic;
```

{*AI12-0321-1*} Atomically performs: `Item := Item - Value;` 14/5

```
function Atomic_Fetch_And_Add                                                       15/5
  (Item  : aliased in out Atomic_Type;
   Value : Atomic_Type) return Atomic_Type
   with Convention => Intrinsic;
```

{*AI12-0321-1*} Atomically performs: `Tmp := Item; Item := Item + Value; return Tmp;` 16/5

```
function Atomic_Fetch_And_Subtract                                                  17/5
  (Item  : aliased in out Atomic_Type;
   Value : Atomic_Type) return Atomic_Type
   with Convention => Intrinsic;
```

{*AI12-0321-1*} Atomically performs: `Tmp := Item; Item := Item - Value; return Tmp;` 18/5

Extensions to Ada 2012

{*AI12-0321-1*} This package is new. 18.a/5

C.6.5 The Package System.Atomic_Operations.Modular_Arithmetic

{*AI12-0364-1*} The language-defined generic package System.Atomic_Operations.Modular_Arithmetic provides operations to perform arithmetic atomically on objects of modular types. 1/5

Static Semantics

{*AI12-0364-1*} The generic library package System.Atomic_Operations.Modular_Arithmetic has the following declaration: 2/5

```
generic                                                                             3/5
   type Atomic_Type is mod <> with Atomic;
package System.Atomic_Operations.Modular_Arithmetic
   with Pure, Nonblocking is

   procedure Atomic_Add (Item  : aliased in out Atomic_Type;                        4/5
                         Value : Atomic_Type)
      with Convention => Intrinsic;
```

5/5
```
      procedure Atomic_Subtract (Item  : aliased in out Atomic_Type;
                                 Value : Atomic_Type)
         with Convention => Intrinsic;
```

6/5
```
      function Atomic_Fetch_And_Add
        (Item  : aliased in out Atomic_Type;
         Value : Atomic_Type) return Atomic_Type
         with Convention => Intrinsic;
```

7/5
```
      function Atomic_Fetch_And_Subtract
        (Item  : aliased in out Atomic_Type;
         Value : Atomic_Type) return Atomic_Type
         with Convention => Intrinsic;
```

8/5
```
      function Is_Lock_Free (Item : aliased Atomic_Type) return Boolean
         with Convention => Intrinsic;
```

9/5
```
   end System.Atomic_Operations.Modular_Arithmetic;
```

10/5 {*AI12-0364-1*} The operations of this package are defined as follows:

11/5
```
   procedure Atomic_Add (Item  : aliased in out Atomic_Type;
                         Value : Atomic_Type)
      with Convention => Intrinsic;
```

12/5 {*AI12-0364-1*} Atomically performs: `Item := Item + Value;`

13/5
```
   procedure Atomic_Subtract (Item  : aliased in out Atomic_Type;
                              Value : Atomic_Type)
      with Convention => Intrinsic;
```

14/5 {*AI12-0364-1*} Atomically performs: `Item := Item - Value;`

15/5
```
   function Atomic_Fetch_And_Add
     (Item  : aliased in out Atomic_Type;
      Value : Atomic_Type) return Atomic_Type
      with Convention => Intrinsic;
```

16/5 {*AI12-0364-1*} Atomically performs: `Tmp := Item; Item := Item + Value; return Tmp;`

17/5
```
   function Atomic_Fetch_And_Subtract
     (Item  : aliased in out Atomic_Type;
      Value : Atomic_Type) return Atomic_Type
      with Convention => Intrinsic;
```

18/5 {*AI12-0364-1*} Atomically performs: `Tmp := Item; Item := Item - Value; return Tmp;`

Extensions to Ada 2012

18.a/5 {*AI12-0364-1*} This package is new.

C.7 Task Information

1/3 {*AI95-00266-02*} {*AI05-0299-1*} [This subclause describes operations and attributes that can be used to obtain the identity of a task. In addition, a package that associates user-defined information with a task is defined. Finally, a package that associates termination procedures with a task or set of tasks is defined.]

Wording Changes from Ada 95

1.a/3 {*AI95-00266-02*} {*AI05-0299-1*} The title and text here were updated to reflect the addition of task termination procedures to this subclause.

C.7.1 The Package Task_Identification

Static Semantics

The following language-defined library package exists: 1

```
{AI95-00362-01} {AI12-0241-1} {AI12-0302-1} {AI12-0399-1} package                    2/5
Ada.Task_Identification
   with Preelaborate, Nonblocking, Global => in out synchronized is
   type Task_Id is private
      with Preelaborable_Initialization;
   Null_Task_Id : constant Task_Id;
   function  "=" (Left, Right : Task_Id) return Boolean;

{8652/0070} {AI95-00101-01} {AI05-0189-1} {AI12-0241-1}    function  Image          3/5
(T : Task_Id) return String;
   function  Current_Task     return Task_Id;
   function  Environment_Task return Task_Id;
   procedure Abort_Task             (T : in Task_Id)
      with Nonblocking => False;

{AI05-0189-1}    function  Is_Terminated          (T : Task_Id) return Boolean;      4/3
   function  Is_Callable            (T : Task_Id) return Boolean;
   function  Activation_Is_Complete (T : Task_Id) return Boolean;
private
   ... -- not specified by the language
end Ada.Task_Identification;
```

Dynamic Semantics

A value of the type Task_Id identifies an existent task. The constant Null_Task_Id does not identify any task. Each object of the type Task_Id is default initialized to the value of Null_Task_Id. 5

The function "=" returns True if and only if Left and Right identify the same task or both have the value Null_Task_Id. 6

The function Image returns an implementation-defined string that identifies T. If T equals Null_Task_Id, Image returns an empty string. 7

Implementation defined: The result of the Task_Identification.Image attribute. 7.a

The function Current_Task returns a value that identifies the calling task. 8

Ramification: {*AI12-0005-1*} The logical threads of control associated with the execution of a given parallel construct all execute as part of the execution of one task (see 9, “Tasks and Synchronization”). Thus, the result returned by a call to Task_Identification.Current_Task is independent of whether the call takes place during the execution of a parallel construct. 8.a.1/5

{*AI05-0189-1*} The function Environment_Task returns a value that identifies the environment task. 8.1/3

{*AI12-0454-1*} The effect of Abort_Task is the same as the abort_statement for the task identified by T. [In addition, if T identifies the environment task, the entire partition is aborted, see E.1.] 9/5

The functions Is_Terminated and Is_Callable return the value of the corresponding attribute of the task identified by T. 10

Ramification: {*8652/0115*} {*AI95-00206-01*} These routines can be called with an argument identifying the environment task. Is_Terminated will always be False for such a call, but Is_Callable (usually True) could be False if the environment task is waiting for the termination of dependent tasks. Thus, a dependent task can use Is_Callable to determine if the main subprogram has completed. 10.a.1/1

{*AI05-0189-1*} The function Activation_Is_Complete returns True if the task identified by T has completed its activation (whether successfully or not). It returns False otherwise. If T identifies the environment task, Activation_Is_Complete returns True after the elaboration of the library_items of the partition has completed. 10.1/3

11 For a prefix T that is of a task type [(after any implicit dereference)], the following attribute is defined:

12 T'Identity Yields a value of the type Task_Id that identifies the task denoted by T.

13 For a prefix E that denotes an entry_declaration, the following attribute is defined:

14/3 E'Caller {*AI05-0262-1*} Yields a value of the type Task_Id that identifies the task whose call is now being serviced. Use of this attribute is allowed only inside an accept_statement, or entry_body after the entry_barrier, corresponding to the entry_declaration denoted by E.

15/5 {*AI12-0231-1*} Program_Error is raised if a value of Null_Task_Id is passed as a parameter to Abort_Task, Activation_Is_Complete, Is_Terminated, and Is_Callable.

16/5 *This paragraph was deleted.*{*AI12-0241-1*}

Bounded (Run-Time) Errors

17/3 {*AI95-00237-01*} {*AI05-0004-1*} It is a bounded error to call the Current_Task function from an entry_body, interrupt handler, or finalization of a task attribute. Program_Error is raised, or an implementation-defined value of the type Task_Id is returned.

17.a/2 **Implementation defined:** The value of Current_Task when in a protected entry, interrupt handler, or finalization of a task attribute.

17.b **Implementation Note:** This value could be Null_Task_Id, or the ID of some user task, or that of an internal task created by the implementation.

17.c/2 **Ramification:** {*AI95-00237-01*} An entry barrier is syntactically part of an entry_body, so a call to Current_Task from an entry barrier is also covered by this rule.

Erroneous Execution

18 If a value of Task_Id is passed as a parameter to any of the operations declared in this package (or any language-defined child of this package), and the corresponding task object no longer exists, the execution of the program is erroneous.

Documentation Requirements

19 The implementation shall document the effect of calling Current_Task from an entry body or interrupt handler.

19.a/2 *This paragraph was deleted.*

19.b/2 **Documentation Requirement:** The effect of calling Current_Task from an entry body or interrupt handler.

20 NOTE 1 This package is intended for use in writing user-defined task scheduling packages and constructing server tasks. Current_Task can be used in conjunction with other operations requiring a task as an argument such as Set_Priority (see D.5).

21 NOTE 2 The function Current_Task and the attribute Caller can return a Task_Id value that identifies the environment task.

Extensions to Ada 95

21.a/2 {*AI95-00362-01*} Task_Identification is now preelaborated, so it can be used in preelaborated units.

Wording Changes from Ada 95

21.b/2 {*8652/0070*} {*AI95-00101-01*} **Corrigendum:** Corrected the mode of the parameter to Abort_Task to **in**.

21.c/2 {*AI95-00237-01*} Corrected the wording to include finalization of a task attribute in the bounded error case; we don't want to specify which task does these operations.

Incompatibilities With Ada 2005

21.d/3 {*AI05-0189-1*} Functions Environment_Task and Activation_Is_Complete are added to Task_Identification. If Task_Identification is referenced in a use_clause, and an entity *E* with a defining_identifier of Environment_Task or

Activation_Is_Complete is defined in a package that is also referenced in a use_clause, the entity *E* may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur.

Wording Changes from Ada 2012

{*AI12-0231-1*} **Correction:** Defined what happens if Null_Task_Id is passed to Activation_Is_Complete. 21.e/5

C.7.2 The Package Task_Attributes

Static Semantics

The following language-defined generic library package exists: 1

```
{AI12-0241-1} {AI12-0302-1} with Ada.Task_Identification; use                    2/5
Ada.Task_Identification;
generic
   type Attribute is private;
   Initial_Value : in Attribute;
package Ada.Task_Attributes
   with Nonblocking, Global => in out synchronized is

   type Attribute_Handle is access all Attribute;                                3

   function Value(T : Task_Id := Current_Task)                                   4
     return Attribute;

   function Reference(T : Task_Id := Current_Task)                               5
     return Attribute_Handle;

   procedure Set_Value(Val : in Attribute;                                       6
                       T : in Task_Id := Current_Task);
   procedure Reinitialize(T : in Task_Id := Current_Task);

end Ada.Task_Attributes;                                                         7
```

Dynamic Semantics

When an instance of Task_Attributes is elaborated in a given active partition, an object of the actual type corresponding to the formal type Attribute is implicitly created for each task (of that partition) that exists and is not yet terminated. This object acts as a user-defined attribute of the task. A task created previously in the partition and not yet terminated has this attribute from that point on. Each task subsequently created in the partition will have this attribute when created. In all these cases, the initial value of the given attribute is Initial_Value. 8

The Value operation returns the value of the corresponding attribute of T. 9

The Reference operation returns an access value that designates the corresponding attribute of T. 10

The Set_Value operation performs any finalization on the old value of the attribute of T and assigns Val to that attribute (see 5.2 and 7.6). 11

The effect of the Reinitialize operation is the same as Set_Value where the Val parameter is replaced with Initial_Value. 12

Implementation Note: In most cases, the attribute memory can be reclaimed at this point. 12.a

For all the operations declared in this package, Tasking_Error is raised if the task identified by T is terminated. Program_Error is raised if the value of T is Null_Task_Id. 13

{*AI95-00237-01*} After a task has terminated, all of its attributes are finalized, unless they have been finalized earlier. When the master of an instantiation of Ada.Task_Attributes is finalized, the corresponding attribute of each task is finalized, unless it has been finalized earlier. 13.1/2

Reason: This is necessary so that a task attribute does not outlive its type. For instance, that's possible if the instantiation is nested, and the attribute is on a library-level task. 13.a/2

13.b/2 **Ramification:** The task owning an attribute cannot, in general, finalize that attribute. That's because the attributes are finalized *after* the task is terminated; moreover, a task may have attributes as soon as it is created; the task may never even have been activated.

Bounded (Run-Time) Errors

13.2/1 {*8652/0071*} {*AI95-00165-01*} If the package Ada.Task_Attributes is instantiated with a controlled type and the controlled type has user-defined Adjust or Finalize operations that in turn access task attributes by any of the above operations, then a call of Set_Value of the instantiated package constitutes a bounded error. The call may perform as expected or may result in forever blocking the calling task and subsequently some or all tasks of the partition.

Erroneous Execution

14 It is erroneous to dereference the access value returned by a given call on Reference after a subsequent call on Reinitialize for the same task attribute, or after the associated task terminates.

14.a **Reason:** This allows the storage to be reclaimed for the object associated with an attribute upon Reinitialize or task termination.

15 If a value of Task_Id is passed as a parameter to any of the operations declared in this package and the corresponding task object no longer exists, the execution of the program is erroneous.

15.1/2 {*8652/0071*} {*AI95-00165-01*} {*AI95-00237-01*} An access to a task attribute via a value of type Attribute_Handle is erroneous if executed concurrently with another such access or a call of any of the operations declared in package Task_Attributes. An access to a task attribute is erroneous if executed concurrently with or after the finalization of the task attribute.

15.a.1/1 **Reason:** There is no requirement of atomicity on accesses via a value of type Attribute_Handle.

15.a.2/2 **Ramification:** A task attribute can only be accessed after finalization through a value of type Attribute_Handle. Operations in package Task_Attributes cannot be used to access a task attribute after finalization, because either the master of the instance has been or is in the process of being left (in which case the instance is out of scope and thus cannot be called), or the associated task is already terminated (in which case Tasking_Error is raised for any attempt to call a task attribute operation).

Implementation Requirements

16/1 {*8652/0071*} {*AI95-00165-01*} For a given attribute of a given task, the implementation shall perform the operations declared in this package atomically with respect to any of these operations of the same attribute of the same task. The granularity of any locking mechanism necessary to achieve such atomicity is implementation defined.

16.a.1/1 **Implementation defined:** Granularity of locking for Task_Attributes.

16.a **Ramification:** Hence, other than by dereferencing an access value returned by Reference, an attribute of a given task can be safely read and updated concurrently by multiple tasks.

17/2 {*AI95-00237-01*} After task attributes are finalized, the implementation shall reclaim any storage associated with the attributes.

Documentation Requirements

18 The implementation shall document the limit on the number of attributes per task, if any, and the limit on the total storage for attribute values per task, if such a limit exists.

19 In addition, if these limits can be configured, the implementation shall document how to configure them.

19.a/2 *This paragraph was deleted.*

19.b/2 **Documentation Requirement:** For package Task_Attributes, limits on the number and size of task attributes, and how to configure any limits.

Metrics

{*AI95-00434-01*} The implementation shall document the following metrics: A task calling the following subprograms shall execute at a sufficiently high priority as to not be preempted during the measurement period. This period shall start just before issuing the call and end just after the call completes. If the attributes of task T are accessed by the measurement tests, no other task shall access attributes of that task during the measurement period. For all measurements described here, the Attribute type shall be a scalar type whose size is equal to the size of the predefined type Integer. For each measurement, two cases shall be documented: one where the accessed attributes are of the calling task [(that is, the default value for the T parameter is used)], and the other, where T identifies another, nonterminated, task. 20/2

The following calls (to subprograms in the Task_Attributes package) shall be measured: 21

- a call to Value, where the return value is Initial_Value; 22
- a call to Value, where the return value is not equal to Initial_Value; 23
- a call to Reference, where the return value designates a value equal to Initial_Value; 24
- a call to Reference, where the return value designates a value not equal to Initial_Value; 25
- {*AI95-00434-01*} a call to Set_Value where the Val parameter is not equal to Initial_Value and the old attribute value is equal to Initial_Value; 26/2
- a call to Set_Value where the Val parameter is not equal to Initial_Value and the old attribute value is not equal to Initial_Value. 27

Documentation Requirement: The metrics for the Task_Attributes package. 27.a/2

Implementation Permissions

{*AI12-0444-1*} An implementation can avoid actually creating the object corresponding to a task attribute until its value is set to something other than that of Initial_Value, or until Reference is called for the task attribute. Similarly, when the value of the attribute is to be reinitialized to that of Initial_Value, the object may instead be finalized and its storage reclaimed, to be recreated when needed later. While the object does not exist, the function Value may simply return Initial_Value, rather than implicitly creating the object. 28/5

Discussion: The effect of this permission can only be observed if the assignment operation for the corresponding type has side effects. 28.a

Implementation Note: {*AI95-00114-01*} This permission means that even though every task has every attribute, storage need only be allocated for those attributes for which function Reference has been invoked or set to a value other than that of Initial_Value. 28.b/2

An implementation is allowed to place restrictions on the maximum number of attributes a task may have, the maximum size of each attribute, and the total storage size allocated for all the attributes of a task. 29

Implementation Advice

{*AI95-00434-01*} {*AI12-0438-1*} Some implementations are targeted to domains in which memory use at run time has to be completely deterministic. For such implementations, it is recommended that the storage for task attributes will be pre-allocated statically and not from the heap. This can be accomplished by either placing restrictions on the number and the size of the attributes of a task, or by using the pre-allocated storage for the first N attribute objects, and the heap for the others. In the latter case, N should be documented. 30/5

Implementation Advice: If the target domain requires deterministic memory use at run time, storage for task attributes should be pre-allocated statically and the number of attributes pre-allocated should be documented. 30.a/2

Discussion: We don't mention “restrictions on the size and number” (that is, limits) in the text for the Annex, because it is covered by the Documentation Requirement above, and we try not to repeat requirements in the Annex (they're enough work to meet without having to do things twice). 30.b/2

30.1/2 {*AI95-00237-01*} Finalization of task attributes and reclamation of associated storage should be performed as soon as possible after task termination.

30.c/2 **Implementation Advice:** Finalization of task attributes and reclamation of associated storage should be performed as soon as possible after task termination.

30.d/2 **Reason:** {*AI95-00237-01*} This is necessary because the normative wording only says that attributes are finalized "after" task termination. Without this advice, waiting until the instance is finalized would meet the requirements (it is after termination, but may be a very long time after termination). We can't say anything more specific than this, as we do not want to require the overhead of an interaction with the tasking system to be done at a specific point.

31/5 NOTE 1 {*AI12-0442-1*} An attribute always exists (after instantiation), and has the initial value. An implementation can avoid using memory to store the attribute value until the first operation that changes the attribute value. The same holds true after Reinitialize.

32/5 NOTE 2 {*AI12-0442-1*} The result of the Reference function is always safe to use in the task body whose attribute is being accessed. However, when the result is being used by another task, the programmer will want to make sure that the task whose attribute is being accessed is not yet terminated. Failing to do so can make the program execution erroneous.

Wording Changes from Ada 95

33.a/2 {*8652/0071*} {*AI95-00165-01*} **Corrigendum:** Clarified that use of task attribute operations from within a task attribute operation (by an Adjust or Finalize call) is a bounded error, and that concurrent use of attribute handles is erroneous.

33.b/2 {*AI95-00237-01*} Clarified the wording so that the finalization takes place after the termination of the task or when the instance is finalized (whichever is sooner).

C.7.3 The Package Task_Termination

Static Semantics

1/2 {*AI95-00266-02*} The following language-defined library package exists:

2/5
```
{AI12-0241-1} {AI12-0302-1} with Ada.Task_Identification;
with Ada.Exceptions;
package Ada.Task_Termination
   with Preelaborate, Nonblocking, Global => in out synchronized is

3/2    type Cause_Of_Termination is (Normal, Abnormal, Unhandled_Exception);

4/2    type Termination_Handler is access protected procedure
         (Cause : in Cause_Of_Termination;
          T     : in Ada.Task_Identification.Task_Id;
          X     : in Ada.Exceptions.Exception_Occurrence);

5/2    procedure Set_Dependents_Fallback_Handler
         (Handler: in Termination_Handler);
       function Current_Task_Fallback_Handler return Termination_Handler;

6/2    procedure Set_Specific_Handler
         (T       : in Ada.Task_Identification.Task_Id;
          Handler : in Termination_Handler);
       function Specific_Handler (T : Ada.Task_Identification.Task_Id)
          return Termination_Handler;

7/2 end Ada.Task_Termination;
```

Dynamic Semantics

8/3 {*AI95-00266-02*} {*AI05-0202-1*} The type Termination_Handler identifies a protected procedure to be executed by the implementation when a task terminates. Such a protected procedure is called a *handler*. In all cases T identifies the task that is terminating. If the task terminates due to completing the last statement of its body, or as a result of waiting on a terminate alternative, and the finalization of the task completes normally, then Cause is set to Normal and X is set to Null_Occurrence. If the task terminates because it is being aborted, then Cause is set to Abnormal; X is set to Null_Occurrence if the finalization of the task completes normally. If the task terminates because of an exception raised by the execution of its task_body, then Cause is set to Unhandled_Exception; X is set to the associated exception occurrence

if the finalization of the task completes normally. Independent of how the task completes, if finalization of the task propagates an exception, then Cause is either Unhandled_Exception or Abnormal, and X is an exception occurrence that identifies the Program_Error exception.

{*AI95-00266-02*} Each task has two termination handlers, a *fall-back handler* and a *specific handler*. The specific handler applies only to the task itself, while the fall-back handler applies only to the dependent tasks of the task. A handler is said to be *set* if it is associated with a nonnull value of type Termination_Handler, and *cleared* otherwise. When a task is created, its specific handler and fall-back handler are cleared. 9/2

{*AI95-00266-02*} {*AI05-0264-1*} The procedure Set_Dependents_Fallback_Handler changes the fall-back handler for the calling task: if Handler is **null**, that fall-back handler is cleared; otherwise, it is set to be Handler.**all**. If a fall-back handler had previously been set it is replaced. 10/3

{*AI95-00266-02*} {*AI05-0264-1*} The function Current_Task_Fallback_Handler returns the fall-back handler that is currently set for the calling task, if one is set; otherwise, it returns **null**. 11/3

{*AI95-00266-02*} {*AI05-0264-1*} The procedure Set_Specific_Handler changes the specific handler for the task identified by T: if Handler is **null**, that specific handler is cleared; otherwise, it is set to be Handler.**all**. If a specific handler had previously been set it is replaced. 12/3

Ramification: {*AI05-0005-1*} This package cannot portably be used to set a handler on the program as a whole. It is possible to call Set_Specific_Handler with the environment task's ID. But any call to the handler would necessarily be a Bounded (Run-Time) Error, as the handler is called after the task's finalization has completed. In the case of the environment task, that includes any possible protected objects, and calling a protected object after it is finalized is a Bounded (Run-Time) Error (see 9.4). This might work in a particular implementation, but it cannot be depended upon. 12.a/3

{*AI95-00266-02*} {*AI05-0264-1*} The function Specific_Handler returns the specific handler that is currently set for the task identified by T, if one is set; otherwise, it returns **null**. 13/3

{*AI95-00266-02*} As part of the finalization of a task_body, after performing the actions specified in 7.6 for finalization of a master, the specific handler for the task, if one is set, is executed. If the specific handler is cleared, a search for a fall-back handler proceeds by recursively following the master relationship for the task. If a task is found whose fall-back handler is set, that handler is executed; otherwise, no handler is executed. 14/2

{*AI95-00266-02*} For Set_Specific_Handler or Specific_Handler, Tasking_Error is raised if the task identified by T has already terminated. Program_Error is raised if the value of T is Ada.Task_Identification.Null_Task_Id. 15/2

{*AI95-00266-02*} An exception propagated from a handler that is invoked as part of the termination of a task has no effect. 16/2

Erroneous Execution

{*AI95-00266-02*} For a call of Set_Specific_Handler or Specific_Handler, if the task identified by T no longer exists, the execution of the program is erroneous. 17/2

Extensions to Ada 95

{*AI95-00266-02*} Package Task_Termination is new. 17.a/2

Wording Changes from Ada 2005

{*AI05-0202-1*} **Correction:** Specified what is passed to the handler if the finalization of the task fails after it is completed. This was not specified at all in Ada 2005, so there is a possibility that some program depended on some other behavior of an implementation. But as this case is very unlikely (and only occurs when there is already a significant bug in the program - so should not occur in fielded systems), we're not listing this as an inconsistency. 17.b/3

Annex D
(normative)
Real-Time Systems

{*AI12-0404-1*} This Annex specifies additional characteristics of Ada implementations intended for real-time systems software. To conform to this Annex, an implementation shall also conform to Annex C, "Systems Programming". 1/5

Metrics

The metrics are documentation requirements; an implementation shall document the values of the language-defined metrics for at least one configuration [of hardware or an underlying system] supported by the implementation, and shall document the details of that configuration. 2

This paragraph was deleted. 2.a/2

Documentation Requirement: The details of the configuration used to generate the values of all metrics. 2.a.1/2

Reason: The actual values of the metrics are likely to depend on hardware configuration details that are variable and generally outside the control of a compiler vendor. 2.b

The metrics do not necessarily yield a simple number. [For some, a range is more suitable, for others a formula dependent on some parameter is appropriate, and for others, it may be more suitable to break the metric into several cases.] Unless specified otherwise, the metrics in this annex are expressed in processor clock cycles. For metrics that require documentation of an upper bound, if there is no upper bound, the implementation shall report that the metric is unbounded. 3

Discussion: There are several good reasons to specify metrics in seconds; there are however equally good reasons to specify them in processor clock cycles. In defining the metrics, we have tried to strike a balance on a case-by-case basis. 3.a

It has been suggested that all metrics should be given names, so that "data-sheets" could be formulated and published by vendors. However the paragraph number can serve that purpose. 3.b

NOTE 1 The specification of the metrics makes a distinction between upper bounds and simple execution times. Where something is just specified as "the execution time of" a piece of code, this leaves one the freedom to choose a nonpathological case. This kind of metric is of the form "there exists a program such that the value of the metric is V". Conversely, the meaning of upper bounds is "there is no program such that the value of the metric is greater than V". This kind of metric can only be partially tested, by finding the value of V for one or more test programs. 4

NOTE 2 The metrics do not cover the whole language; they are limited to features that are specified in Annex C, "Systems Programming" and in this Annex. The metrics are intended to provide guidance to potential users as to whether a particular implementation of such a feature is going to be adequate for a particular real-time application. As such, the metrics are aimed at known implementation choices that can result in significant performance differences. 5

NOTE 3 The purpose of the metrics is not necessarily to provide fine-grained quantitative results or to serve as a comparison between different implementations on the same or different platforms. Instead, their goal is rather qualitative; to define a standard set of approximate values that can be measured and used to estimate the general suitability of an implementation, or to evaluate the comparative utility of certain features of an implementation for a particular real-time application. 6

Extensions to Ada 83

This Annex is new to Ada 95. 6.a

D.1 Task Priorities

{*AI05-0299-1*} [This subclause specifies the priority model for real-time systems. In addition, the methods for specifying priorities are defined.] 1/3

Paragraphs 2 through 6 were moved to Annex J, "Obsolescent Features".

Static Semantics

6.1/3 {*AI05-0229-1*} For a task type (including the anonymous type of a single_task_declaration), protected type (including the anonymous type of a single_protected_declaration), or subprogram, the following language-defined representation aspects may be specified:

6.2/3 Priority The aspect Priority is an expression, which shall be of type Integer.

6.a/3 **Aspect Description for Priority:** Priority of a task object or type, or priority of a protected object or type; the priority is not in the interrupt range.

6.3/3 Interrupt_Priority
The aspect Interrupt_Priority is an expression, which shall be of type Integer.

6.b/3 **Aspect Description for Interrupt_Priority:** Priority of a task object or type, or priority of a protected object or type; the priority is in the interrupt range.

Legality Rules

7/3 *This paragraph was deleted.*{*AI05-0229-1*}

8/3 {*AI05-0229-1*} If the Priority aspect is specified for a subprogram, the expression shall be static, and its value shall be in the range of System.Priority.

8.a **Reason:** This value is needed before it gets elaborated, when the environment task starts executing.

8.1/3 {*AI05-0229-1*} At most one of the Priority and Interrupt_Priority aspects may be specified for a given entity.

8.b/3 **Ramification:** This includes specifying via pragmas (see J.15.11). Note that 13.1 prevents multiple specifications of a single representation aspect by any means.

8.2/3 {*AI05-0229-1*} Neither of the Priority or Interrupt_Priority aspects shall be specified for a synchronized interface type.

Static Semantics

9 The following declarations exist in package System:

10
```
subtype Any_Priority is Integer range implementation-defined;
subtype Priority is Any_Priority
   range Any_Priority'First .. implementation-defined;
subtype Interrupt_Priority is Any_Priority
   range Priority'Last+1 .. Any_Priority'Last;
```

11
```
Default_Priority : constant Priority := (Priority'First + Priority'Last)/2;
```

11.a **Implementation defined:** The declarations of Any_Priority and Priority.

12 The full range of priority values supported by an implementation is specified by the subtype Any_Priority. The subrange of priority values that are high enough to require the blocking of one or more interrupts is specified by the subtype Interrupt_Priority. [The subrange of priority values below System.-Interrupt_Priority'First is specified by the subtype System.Priority.]

13/3 *This paragraph was deleted.*{*AI05-0229-1*}

Dynamic Semantics

14/3 {*AI05-0229-1*} The Priority aspect has no effect if it is specified for a subprogram other than the main subprogram; the Priority value is not associated with any task.

15/5 {*AI12-0404-1*} A *task priority* is an integer value that indicates a degree of urgency and is the basis for resolving competing demands of tasks for resources. Unless otherwise specified, whenever tasks compete for processors or other implementation-defined resources, the resources are allocated to the task with the highest priority value. The *base priority* of a task is the priority with which it was created, or to which it was later set by Dynamic_Priorities.Set_Priority (see D.5). At all times, a task also has an *active priority*,

which generally is its base priority unless it inherits a priority from other sources. *Priority inheritance* is the process by which the priority of a task or other entity (for example, a protected object; see D.3) is used in the evaluation of another task's active priority.

Implementation defined: Implementation-defined execution resources. 15.a

{*AI05-0229-1*} The effect of specifying a Priority or Interrupt_Priority aspect for a protected type or single_protected_declaration is discussed in D.3. 16/3

{*AI05-0229-1*} {*AI12-0081-1*} The expression specified for the Priority or Interrupt_Priority aspect of a task type is evaluated each time an object of the task type is created (see 9.1). For the Priority aspect, the value of the expression is converted to the subtype Priority; for the Interrupt_Priority aspect, this value is converted to the subtype Any_Priority. The priority value is then associated with the task object. 17/4

{*AI05-0229-1*} Likewise, the priority value is associated with the environment task if the aspect is specified for the main subprogram. 18/3

{*AI05-0229-1*} The initial value of a task's base priority is specified by default or by means of a Priority or Interrupt_Priority aspect. [After a task is created, its base priority can be changed only by a call to Dynamic_Priorities.Set_Priority (see D.5).] The initial base priority of a task in the absence of an aspect is the base priority of the task that creates it at the time of creation (see 9.1). If the aspect Priority is not specified for the main subprogram, the initial base priority of the environment task is System.Default_Priority. [The task's active priority is used when the task competes for processors. Similarly, the task's active priority is used to determine the task's position in any queue when Priority_Queuing is specified (see D.4).] 19/3

{*AI95-00357-01*} At any time, the active priority of a task is the maximum of all the priorities the task is inheriting at that instant. For a task that is not held (see D.11), its base priority is a source of priority inheritance unless otherwise specified for a particular task dispatching policy. Other sources of priority inheritance are specified under the following conditions: 20/2

Discussion: Other parts of the annex, e.g. D.11, define other sources of priority inheritance. 20.a

- {*8652/0072*} {*AI95-00092-01*} During activation, a task being activated inherits the active priority that its activator (see 9.2) had at the time the activation was initiated. 21/1
- {*8652/0072*} {*AI95-00092-01*} During rendezvous, the task accepting the entry call inherits the priority of the entry call (see 9.5.3 and D.4). 22/1
- {*AI12-0276-1*} While starting a protected action on a protected object when the FIFO_Spinning admission policy is in effect, a task inherits the ceiling priority of the protected object (see 9.5, D.3, and D.4.1). 22.1/5

  Reason: {*AI12-0005-1*} {*AI12-0276-1*} Priority inheritance is needed for FIFO_Spinning to ensure that lower priority tasks that initiate spin waiting earlier than other higher priority tasks continue to spin to ensure that they can be granted the resource when it becomes available in order to support FIFO ordering. Note that this rule only matters when tasks that can initiate a protected action on an object P can be on a different processor than P. In particular, this rule does not matter on a monoprocessor. 22.a/5
- {*AI12-0404-1*} While a task executes a protected action on a protected object, the task inherits the ceiling priority of the protected object (see 9.5 and D.3). 23/5

In all of these cases, the priority ceases to be inherited as soon as the condition calling for the inheritance no longer exists. 24

Implementation Requirements

The range of System.Interrupt_Priority shall include at least one value. 25

The range of System.Priority shall include at least 30 values. 26

27 NOTE 1 The priority expression can include references to discriminants of the enclosing type.

28 NOTE 2 It is a consequence of the active priority rules that at the point when a task stops inheriting a priority from another source, its active priority is re-evaluated. This is in addition to other instances described in this Annex for such re-evaluation.

29/5 NOTE 3 {*AI05-0248-1*} {*AI12-0440-1*} An implementation can provide a nonstandard mode in which tasks inherit priorities under conditions other than those specified above.

29.a/3 **Ramification:** {*AI05-0229-1*} The use of a Priority or Interrupt_Priority aspect does not require the package System to be named in a with_clause for the enclosing compilation_unit.

Extensions to Ada 83

29.b The priority of a task is per-object and not per-type.

29.c Priorities need not be static anymore (except for the main subprogram).

Wording Changes from Ada 83

29.d The description of the Priority pragma has been moved to this annex.

Wording Changes from Ada 95

29.e/2 {*8652/0072*} {*AI95-00092-01*} **Corrigendum:** Clarified that dynamic priority changes are not transitive - that is, they don't apply to tasks that are being activated by or in rendezvous with the task that had its priority changed.

29.f/2 {*AI95-00357-01*} Generalized the definition of priority inheritance to take into account the differences between the existing and new dispatching policies.

Extensions to Ada 2005

29.g/3 {*AI05-0229-1*} Aspects Priority and Interrupt_Priority are new; pragmas Priority and Interrupt_Priority are now obsolescent.

Wording Changes from Ada 2012

29.h/4 {*AI12-0081-1*} **Corrigendum:** Clarified when the Priority and Interrupt_Priority aspect expressions are evaluated.

29.i/5 {*AI12-0276-1*} Added an additional case of priority inheritance when the new admission policy FIFO_Spinning is in effect.

D.2 Priority Scheduling

1/3 {*AI95-00321-01*} {*AI05-0299-1*} [This subclause describes the rules that determine which task is selected for execution when more than one task is ready (see 9).]

Wording Changes from Ada 95

1.a/3 {*AI95-00321-01*} {*AI05-0299-1*} This introduction is simplified in order to reflect the rearrangement and expansion of this subclause.

D.2.1 The Task Dispatching Model

1/2 {*AI95-00321-01*} [The task dispatching model specifies task scheduling, based on conceptual priority-ordered ready queues.]

Static Semantics

1.1/2 {*AI95-00355-01*} The following language-defined library package exists:

1.2/5
```
{AI05-0166-1} {AI12-0241-1} {AI12-0302-1} package Ada.Dispatching
  with Preelaborate, Nonblocking, Global => in out synchronized is
```

1.3/5
```
   {AI05-0166-1} {AI12-0241-1}   procedure Yield
      with Nonblocking => False;
```

1.4/3
```
   {AI05-0166-1}   Dispatching_Policy_Error : exception;
end Ada.Dispatching;
```

Dispatching serves as the parent of other language-defined library units concerned with task dispatching. 1.5/2

{*AI12-0279-1*} For a noninstance subprogram (including a generic formal subprogram), a generic subprogram, or an entry, the following language-defined aspect may be specified with an aspect_specification (see 13.1.1): 1.6/5

Yield The type of aspect Yield is Boolean. 1.7/5

Aspect Description for Yield: Ensures that a callable entity includes a task dispatching point. 1.a/5

If directly specified, the aspect_definition shall be a static expression. If not specified (including by inheritance), the aspect is False. 1.8/5

{*AI12-0279-1*} {*AI12-0294-1*} If a Yield aspect is specified True for a primitive subprogram *S* of a type *T*, then the aspect is inherited by the corresponding primitive subprogram of each descendant of *T*. 1.9/5

Legality Rules

{*AI12-0279-1*} {*AI12-0294-1*} If the Yield aspect is specified for a dispatching subprogram that inherits the aspect, the specified value shall be confirming. 1.10/5

{*AI12-0279-1*} {*AI12-0294-1*} If the Nonblocking aspect (see 9.5) of the associated callable entity is statically True, the Yield aspect shall not be specified as True. For a callable entity that is declared within a generic body, this rule is checked assuming that any nonstatic Nonblocking attributes in the expression of the Nonblocking aspect of the entity are statically True. 1.11/5

Reason: {*AI12-0294-1*} The second sentence here is an assume-the-worst rule. The only Nonblocking attributes that are nonstatic are those that depend, directly or indirectly, on the nonblocking aspect of a generic formal parameter. We have to assume these might in fact have the value True if given an appropriate actual entity. 1.b/5

{*AI12-0294-1*} In addition to the places where Legality Rules normally apply (see 12.3), these rules also apply in the private part of an instance of a generic unit. 1.12/5

Dynamic Semantics

{*AI95-00321-01*} {*AI12-0454-1*} A task can become a *running task* only if it is ready (see Clause 9) and the execution resources required by that task are available. Processors are allocated to tasks based on each task's active priority. 2/5

It is implementation defined whether, on a multiprocessor, a task that is waiting for access to a protected object keeps its processor busy. 3

Implementation defined: Whether, on a multiprocessor, a task that is waiting for access to a protected object keeps its processor busy. 3.a

{*AI95-00321-01*} {*AI12-0119-1*} *Task dispatching* is the process by which a logical thread of control associated with a ready task is selected for execution on a processor. This selection is done during the execution of such a logical thread of control, at certain points called *task dispatching points*. Such a logical thread of control reaches a task dispatching point whenever it becomes blocked, and when its associated task terminates. [Other task dispatching points are defined throughout this Annex for specific policies.] Below we talk in terms of tasks, but in the context of a parallel construct, a single task can be represented by multiple logical threads of control, each of which can appear separately on a ready queue. 4/5

Ramification: On multiprocessor systems, more than one task can be chosen, at the same time, for execution on more than one processor, as explained below. 4.a

{*AI95-00321-01*} *Task dispatching policies* are specified in terms of conceptual *ready queues* and task states. A ready queue is an ordered list of ready tasks. The first position in a queue is called the *head of the queue*, and the last position is called the *tail of the queue*. A task is *ready* if it is in a ready queue, or if it is running. Each processor has one ready queue for each priority value. At any instant, each ready 5/2

queue of a processor contains exactly the set of tasks of that priority that are ready for execution on that processor, but are not running on any processor; that is, those tasks that are ready, are not running on any processor, and can be executed using that processor and other available resources. A task can be on the ready queues of more than one processor.

5.a **Discussion:** The core language defines a ready task as one that is not blocked. Here we refine this definition and talk about ready queues.

6/2 {*AI95-00321-01*} Each processor also has one *running task*, which is the task currently being executed by that processor. Whenever a task running on a processor reaches a task dispatching point it goes back to one or more ready queues; a task (possibly the same task) is then selected to run on that processor. The task selected is the one at the head of the highest priority nonempty ready queue; this task is then removed from all ready queues to which it belongs.

6.a **Discussion:** There is always at least one task to run, if we count the idle task.

7/5 {*AI95-00321-01*} {*AI05-0166-1*} {*AI12-0241-1*} A call of Yield and a delay_statement are task dispatching points for all language-defined policies.

7.a/2 *This paragraph was deleted.*

8/5 {*AI95-00321-01*} {*AI12-0279-1*} If the Yield aspect has the value True, then a call to procedure Yield is included within the body of the associated callable entity, and invoked immediately prior to returning from the body if and only if no other task dispatching points were encountered during the execution of the body.

8.a/2 *This paragraph was deleted.*

Implementation Permissions

9/2 {*AI95-00321-01*} An implementation is allowed to define additional resources as execution resources, and to define the corresponding allocation policies for them. Such resources may have an implementation-defined effect on task dispatching.

9.a/2 **Implementation defined:** The effect of implementation-defined execution resources on task dispatching.

10 An implementation may place implementation-defined restrictions on tasks whose active priority is in the Interrupt_Priority range.

10.a/3 **Ramification:** {*AI05-0229-1*} For example, on some operating systems, it might be necessary to disallow them altogether. This permission applies to tasks whose priority is set to interrupt level for any reason: via an aspect, via a call to Dynamic_Priorities.Set_Priority, or via priority inheritance.

10.1/5 {*AI95-00321-01*} {*AI12-0299-1*} Unless otherwise specified for a task dispatching policy, an implementation may add additional points at which task dispatching may occur, in an implementation-defined manner.

10.b/5 **Reason:** {*AI12-0299-1*} This permission is intended to allow the implementation of Ada tasks in terms of target system threads, which may have additional conditions that cause task dispatching. For instance, for Linux threads, page faults are task dispatching points.

10.c/5 **Discussion:** {*AI12-0299-1*} The Non_Preemptive_FIFO_Within_Priorities task dispatching policy (see D.2.4) does not allow additional task dispatching points.

11 NOTE 1 Clause 9 specifies under which circumstances a task becomes ready. The ready state is affected by the rules for task activation and termination, delay statements, and entry calls. When a task is not ready, it is said to be blocked.

12/5 NOTE 2 {*AI12-0442-1*} An example of a possible implementation-defined execution resource is a page of physical memory, which must be loaded with a particular page of virtual memory before a task can continue execution.

13 NOTE 3 The ready queues are purely conceptual; there is no requirement that such lists physically exist in an implementation.

14 NOTE 4 While a task is running, it is not on any ready queue. Any time the task that is running on a processor is added to a ready queue, a new running task is selected for that processor.

NOTE 5 In a multiprocessor system, a task can be on the ready queues of more than one processor. At the extreme, if several processors share the same set of ready tasks, the contents of their ready queues is identical, and so they can be viewed as sharing one ready queue, and can be implemented that way. [Thus, the dispatching model covers multiprocessors where dispatching is implemented using a single ready queue, as well as those with separate dispatching domains.] 15

NOTE 6 The priority of a task is determined by rules specified in this subclause, and under D.1, “Task Priorities”, D.3, “Priority Ceiling Locking”, and D.5, “Dynamic Priorities”. 16

NOTE 7 {*AI95-00321-01*} The setting of a task's base priority as a result of a call to Set_Priority does not always take effect immediately when Set_Priority is called. The effect of setting the task's base priority is deferred while the affected task performs a protected action. 17/2

Wording Changes from Ada 95

{*AI95-00321-01*} {*AI05-0005-1*} This description is simplified to describe only the parts of the dispatching model common to all policies. In particular, rules about preemption are moved elsewhere. This makes it easier to add other policies (which might not involve preemption). 17.a/3

Incompatibilities With Ada 2005

{*AI05-0166-1*} Procedure Yield is added to Dispatching. If Dispatching is referenced in a use_clause, and an entity *E* with a defining_identifier of Yield is defined in a package that is also referenced in a use_clause, the entity *E* may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur. 17.b/3

{*AI05-0166-1*} {*AI12-0005-1*} Package Dispatching was a Pure package, but now is Preelaborated with the addition of Yield. This is incompatible as Dispatching can no longer be depended upon from a Pure package. This should happen rarely in practice as the only contents was the exception Dispatching_Policy_Error and none of the child packages that could raise that exception are pure. 17.c/4

Inconsistencies With Ada 2012

{*AI12-0299-1*} **Correction:** Substantially reduced the Implementation Permission that used to allow “altering” task dispatching points to only allow adding task dispatching points. If an implementation was using this permission to remove task dispatching points, and a program depended on that behavior to work, it could fail when used with Ada 2022. We are not aware of any such implementations, and such behavior was never portable to other implementations, so we do not expect this to matter in practice. 17.d/5

Extensions to Ada 2012

{*AI12-0279-1*} {*AI12-0294-1*} Aspect Yield is new. 17.e/5

Wording Changes from Ada 2012

{*AI12-0119-1*} Redid the description of task dispatching to include the separate threads of control that can be started by a parallel construct. 17.f/5

D.2.2 Task Dispatching Pragmas

{*AI95-00355-01*} {*AI05-0299-1*} [This subclause allows a single task dispatching policy to be defined for all priorities, or the range of priorities to be split into subranges that are assigned individual dispatching policies.] 0.1/3

Syntax

The form of a pragma Task_Dispatching_Policy is as follows: 1

pragma Task_Dispatching_Policy(*policy*_identifier); 2

{*AI95-00355-01*} The form of a pragma Priority_Specific_Dispatching is as follows: 2.1/2

pragma Priority_Specific_Dispatching (2.2/2
*policy*_identifier, *first_priority*_expression, *last_priority*_expression);

Name Resolution Rules

2.3/2 {*AI95-00355-01*} The expected type for *first_priority_*expression and *last_priority_*expression is Integer.

Legality Rules

3/2 {*AI95-00321-01*} {*AI95-00355-01*} The *policy_*identifier used in a pragma Task_Dispatching_Policy shall be the name of a task dispatching policy.

3.a/2 *This paragraph was deleted.*

3.1/2 {*AI95-00355-01*} The *policy_*identifier used in a pragma Priority_Specific_Dispatching shall be the name of a task dispatching policy.

3.2/2 {*AI95-00355-01*} Both *first_priority_*expression and *last_priority_*expression shall be static expressions in the range of System.Any_Priority; *last_priority_*expression shall have a value greater than or equal to *first_priority_*expression.

Static Semantics

3.3/2 {*AI95-00355-01*} Pragma Task_Dispatching_Policy specifies the single task dispatching policy.

3.4/2 {*AI95-00355-01*} Pragma Priority_Specific_Dispatching specifies the task dispatching policy for the specified range of priorities. Tasks with base priorities within the range of priorities specified in a Priority_Specific_Dispatching pragma have their active priorities determined according to the specified dispatching policy. Tasks with active priorities within the range of priorities specified in a Priority_Specific_Dispatching pragma are dispatched according to the specified dispatching policy.

3.b/2 **Reason:** {*AI95-00355-01*} Each ready queue is managed by exactly one policy. Anything else would be chaos. The ready queue is determined by the active priority. However, how the active priority is calculated is determined by the policy; in order to break out of this circle, we have to say that the active priority is calculated by the method determined by the policy of the base priority.

3.5/3 {*AI95-00355-01*} {*AI05-0262-1*} If a partition contains one or more Priority_Specific_Dispatching pragmas, the dispatching policy for priorities not covered by any Priority_Specific_Dispatching pragmas is FIFO_Within_Priorities.

Post-Compilation Rules

4/2 {*AI95-00355-01*} A Task_Dispatching_Policy pragma is a configuration pragma. A Priority_Specific_Dispatching pragma is a configuration pragma.

4.1/2 {*AI95-00355-01*} The priority ranges specified in more than one Priority_Specific_Dispatching pragma within the same partition shall not be overlapping.

4.2/2 {*AI95-00355-01*} If a partition contains one or more Priority_Specific_Dispatching pragmas it shall not contain a Task_Dispatching_Policy pragma.

5/2 *This paragraph was deleted.*{*AI95-00333-01*}

Dynamic Semantics

6/2 {*AI95-00355-01*} [A *task dispatching policy* specifies the details of task dispatching that are not covered by the basic task dispatching model. These rules govern when tasks are inserted into and deleted from the ready queues.] A single task dispatching policy is specified by a Task_Dispatching_Policy pragma. Pragma Priority_Specific_Dispatching assigns distinct dispatching policies to subranges of System.Any_Priority.

{*AI95-00355-01*} If neither pragma applies to any of the program units comprising a partition, the task dispatching policy for that partition is unspecified. 6.1/2

{*AI95-00355-01*} {*AI05-0262-1*} If a partition contains one or more Priority_Specific_Dispatching pragmas, a task dispatching point occurs for the currently running task of a processor whenever there is a nonempty ready queue for that processor with a higher priority than the priority of the running task. 6.2/3

Discussion: {*AI05-0005-1*} If we have priority specific dispatching then we want preemption across the entire range of priorities. That prevents higher priority tasks from being blocked by lower priority tasks that have a different policy. On the other hand, if we have a single policy for the entire partition, we want the characteristics of that policy to apply for preemption; specifically, we might not require any preemption. Note that policy Non_Preemptive_FIFO_Within_Priorities is not allowed in a priority specific dispatching pragma. 6.a/3

{*AI95-00355-01*} A task that has its base priority changed may move from one dispatching policy to another. It is immediately subject to the new dispatching policy. 6.3/2

Ramification: Once subject to the new dispatching policy, it may be immediately preempted or dispatched, according the rules of the new policy. 6.b/2

Paragraphs 7 through 13 were moved to D.2.3.

Implementation Requirements

{*AI95-00333-01*} {*AI95-00355-01*} An implementation shall allow, for a single partition, both the locking policy (see D.3) to be specified as Ceiling_Locking and also one or more Priority_Specific_Dispatching pragmas to be given. 13.1/2

Documentation Requirements

Paragraphs 14 through 16 were moved to D.2.3.

This paragraph was deleted. 16.a/2

Implementation Permissions

{*AI95-00256-01*} {*AI12-0444-1*} Implementations are allowed to define other task dispatching policies, but are not required to support specifying more than one task dispatching policy per partition. 17/5

{*AI95-00355-01*} {*AI12-0444-1*} An implementation is not required to support pragma Priority_Specific_Dispatching if it is infeasible to support it in the target environment. 18/5

Implementation defined: Implementation defined task dispatching policies. 18.a/2

Paragraphs 19 through 21 were deleted.

Extensions to Ada 95

{*AI95-00333-01*} **Amendment Correction:** It is no longer required to specify Ceiling_Locking with the language-defined task dispatching policies; we only require that implementations *allow* them to be used together. 21.a/2

{*AI95-00355-01*} {*AI05-0005-1*} **Pragma** Priority_Specific_Dispatching is new; it allows the specification of different policies for different priorities. 21.b/3

Wording Changes from Ada 95

{*AI95-00256-01*} Clarified that an implementation need support only one task dispatching policy (of any kind, language-defined or otherwise) per partition. 21.c/2

{*AI95-00321-01*} {*AI05-0005-1*} This description is simplified to describe only the rules for the Task_Dispatching_Policy pragma that are common to all policies. In particular, rules about preemption are moved elsewhere. This makes it easier to add other policies (which might not involve preemption). 21.d/3

D.2.3 Preemptive Dispatching

{*AI95-00321-01*} {*AI05-0299-1*} [This subclause defines a preemptive task dispatching policy.] 1/3

Static Semantics

2/2 {*AI95-00355-01*} The *policy_*identifier FIFO_Within_Priorities is a task dispatching policy.

Dynamic Semantics

3/2 {*AI95-00321-01*} When FIFO_Within_Priorities is in effect, modifications to the ready queues occur only as follows:

4/2 • {*AI95-00321-01*} When a blocked task becomes ready, it is added at the tail of the ready queue for its active priority.

5/2 • When the active priority of a ready task that is not running changes, or the setting of its base priority takes effect, the task is removed from the ready queue for its old active priority and is added at the tail of the ready queue for its new active priority, except in the case where the active priority is lowered due to the loss of inherited priority, in which case the task is added at the head of the ready queue for its new active priority.

6/2 • When the setting of the base priority of a running task takes effect, the task is added to the tail of the ready queue for its active priority.

7/2 • When a task executes a delay_statement that does not result in blocking, it is added to the tail of the ready queue for its active priority.

7.a/2 **Ramification:** If the delay does result in blocking, the task moves to the "delay queue", not to the ready queue.

8/2 {*AI95-00321-01*} Each of the events specified above is a task dispatching point (see D.2.1).

9/2 {*AI95-00321-01*} A task dispatching point occurs for the currently running task of a processor whenever there is a nonempty ready queue for that processor with a higher priority than the priority of the running task. The currently running task is said to be *preempted* and it is added at the head of the ready queue for its active priority.

Implementation Requirements

10/2 {*AI95-00333-01*} An implementation shall allow, for a single partition, both the task dispatching policy to be specified as FIFO_Within_Priorities and also the locking policy (see D.3) to be specified as Ceiling_Locking.

10.a/2 **Reason:** This is the preferred combination of the FIFO_Within_Priorities policy with a locking policy, and we want that combination to be portable.

Documentation Requirements

11/2 {*AI95-00321-01*} *Priority inversion* is the duration for which a task remains at the head of the highest priority nonempty ready queue while the processor executes a lower priority task. The implementation shall document:

12/2 • The maximum priority inversion a user task can experience due to activity of the implementation (on behalf of lower priority tasks), and

12.a/2 **Documentation Requirement:** The maximum priority inversion a user task can experience from the implementation.

13/2 • whether execution of a task can be preempted by the implementation processing of delay expirations for lower priority tasks, and if so, for how long.

13.a/2 **Documentation Requirement:** The amount of time that a task can be preempted for processing on behalf of lower-priority tasks.

14/2 NOTE 1 {*AI95-00321-01*} If the active priority of a running task is lowered due to loss of inherited priority (as it is on completion of a protected operation) and there is a ready task of the same active priority that is not running, the running task continues to run (provided that there is no higher priority task).

15/2 NOTE 2 {*AI95-00321-01*} Setting the base priority of a ready task causes the task to move to the tail of the queue for its active priority, regardless of whether the active priority of the task actually changes.

Wording Changes from Ada 95

{*AI95-00321-01*} This subclause is new; it mainly consists of text that was found in D.2.1 and D.2.2 in Ada 95. This was separated out so the definition of additional policies was easier. 15.a/2

{*AI95-00333-01*} We require that implementations allow this policy and Ceiling_Locking together. 15.b/2

{*AI95-00355-01*} We explicitly defined FIFO_Within_Priorities to be a task dispatching policy. 15.c/2

D.2.4 Non-Preemptive Dispatching

{*AI95-00298-01*} {*AI05-0299-1*} [This subclause defines a non-preemptive task dispatching policy.] 1/3

Static Semantics

{*AI95-00298-01*} {*AI95-00355-01*} The *policy*_identifier Non_Preemptive_FIFO_Within_Priorities is a task dispatching policy. 2/2

{*AI05-0166-1*} The following language-defined library package exists: 2.1/3

```
{AI12-0241-1} {AI12-0302-1} package Ada.Dispatching.Non_Preemptive                2.2/5
  with Preelaborate, Nonblocking, Global => in out synchronized is
  procedure Yield_To_Higher;
  procedure Yield_To_Same_Or_Higher renames Yield;
end Ada.Dispatching.Non_Preemptive;
```

{*AI05-0166-1*} {*AI05-0264-1*} A call of Yield_To_Higher is a task dispatching point for this policy. If the task at the head of the highest priority ready queue has a higher active priority than the calling task, then the calling task is preempted. 2.3/3

Ramification: For language-defined policies other than Non_Preemptive_FIFO_Within_Priorities, a higher priority task should never be on a ready queue while a lower priority task is executed. Thus, for such policies, Yield_To_Higher does nothing. 2.a/3

Yield_To_Higher is *not* a potentially blocking operation; it can be used during a protected operation. That is allowed, as under the predefined Ceiling_Locking policy any task with a higher priority than the protected operation cannot call the operation (that would violate the locking policy). An implementation-defined locking policy may need to define the semantics of Yield_To_Higher differently. 2.b/3

Legality Rules

{*AI95-00355-01*} Non_Preemptive_FIFO_Within_Priorities shall not be specified as the *policy*_identifier of pragma Priority_Specific_Dispatching (see D.2.2). 3/2

Reason: The non-preemptive nature of this policy could cause the policies of higher priority tasks to malfunction, missing deadlines and having unlimited priority inversion. That would render the use of such policies impotent and misleading. As such, this policy only makes sense for a complete system. 3.a/2

Dynamic Semantics

{*AI95-00298-01*} When Non_Preemptive_FIFO_Within_Priorities is in effect, modifications to the ready queues occur only as follows: 4/2

- {*AI95-00298-01*} When a blocked task becomes ready, it is added at the tail of the ready queue for its active priority. 5/2
- When the active priority of a ready task that is not running changes, or the setting of its base priority takes effect, the task is removed from the ready queue for its old active priority and is added at the tail of the ready queue for its new active priority. 6/2
- When the setting of the base priority of a running task takes effect, the task is added to the tail of the ready queue for its active priority. 7/2
- When a task executes a delay_statement that does not result in blocking, it is added to the tail of the ready queue for its active priority. 8/2

8.a/2 **Ramification:** If the delay does result in blocking, the task moves to the “delay queue”, not to the ready queue.

9/3 {*AI05-0166-1*} For this policy, blocking or termination of a task, a delay_statement, a call to Yield_To_Higher, and a call to Yield_To_Same_Or_Higher or Yield are the only task dispatching points (see D.2.1).

9.a/3 **Ramification:** {*AI05-0166-1*} A delay_statement is always a task dispatching point even if it is not blocking. Similarly, a call to Yield_To_Higher is never blocking, but it is a task dispatching point In each of these cases, they can cause the current task to stop running (it is still ready). Otherwise, the running task continues to run until it is blocked.

9.b/5 {*AI12-0299-1*} This rule supersedes the Implementation Permission of D.2.1; an implementation that adds additional task dispatching points to this policy is incorrect.

Implementation Requirements

10/2 {*AI95-00333-01*} An implementation shall allow, for a single partition, both the task dispatching policy to be specified as Non_Preemptive_FIFO_Within_Priorities and also the locking policy (see D.3) to be specified as Ceiling_Locking.

10.a/2 **Reason:** This is the preferred combination of the Non_Preemptive_FIFO_Within_Priorities policy with a locking policy, and we want that combination to be portable.

Implementation Permissions

11/3 {*AI95-00298-01*} {*AI05-0229-1*} {*AI05-0269-1*} Since implementations are allowed to round all ceiling priorities in subrange System.Priority to System.Priority'Last (see D.3), an implementation may allow a task of a partition using the Non_Premptive_FIFO_Within_Priorities policy to execute within a protected object without raising its active priority provided the associated protected unit does not contain any subprograms with aspects Interrupt_Handler or Attach_Handler specified, nor does the unit have aspect Interrupt_Priority specified. When the locking policy (see D.3) is Ceiling_Locking, an implementation taking advantage of this permission shall ensure that a call to Yield_to_Higher that occurs within a protected action uses the ceiling priority of the protected object (rather than the active priority of the task) when determining whether to preempt the task.

11.a.1/3 **Reason:** {*AI05-0269-1*} We explicitly require that the ceiling priority be used in calls to Yield_to_Higher in order to prevent a risk of priority inversion and consequent loss of mutual exclusion when Yield_to_Higher is used in a protected object. This requirement might lessen the value of the permission (as the current Ceiling_Priority will have to be maintained in the TCB), but loss of mutual exclusion cannot be tolerated. The primary benefit of the permission (eliminating the need for preemption at the end of a protected action) is still available. As noted above, an implementation-defined locking policy will need to specify the semantics of Yield_to_Higher, including this case.

Extensions to Ada 95

11.a/2 {*AI95-00298-01*} {*AI95-00355-01*} Policy Non_Preemptive_FIFO_Within_Priorities is new.

Extensions to Ada 2005

11.b/3 {*AI05-0166-1*} Package Dispatching.Non_Preemptive is new.

D.2.5 Round Robin Dispatching

1/3 {*AI95-00355-01*} {*AI05-0299-1*} [This subclause defines the task dispatching policy Round_Robin_Within_Priorities and the package Round_Robin.]

Static Semantics

2/2 {*AI95-00355-01*} The *policy*_identifier Round_Robin_Within_Priorities is a task dispatching policy.

{*AI95-00355-01*} The following language-defined library package exists: 3/2

```
{AI12-0241-1} {AI12-0302-1} with System;                                    4/5
with Ada.Real_Time;
package Ada.Dispatching.Round_Robin
  with Nonblocking, Global => in out synchronized is
  Default_Quantum : constant Ada.Real_Time.Time_Span :=
            implementation-defined;
  procedure Set_Quantum (Pri     : in System.Priority;
                         Quantum : in Ada.Real_Time.Time_Span);
  procedure Set_Quantum (Low, High : in System.Priority;
                         Quantum   : in Ada.Real_Time.Time_Span);
  function Actual_Quantum (Pri : System.Priority)
            return Ada.Real_Time.Time_Span;
  function Is_Round_Robin (Pri : System.Priority) return Boolean;
end Ada.Dispatching.Round_Robin;
```

Implementation defined: The value of Default_Quantum in Dispatching.Round_Robin. 4.a.1/2

{*AI95-00355-01*} When task dispatching policy Round_Robin_Within_Priorities is the single policy in effect for a partition, each task with priority in the range of System.Interrupt_Priority is dispatched according to policy FIFO_Within_Priorities. 5/2

Dynamic Semantics

{*AI95-00355-01*} The procedures Set_Quantum set the required Quantum value for a single priority level Pri or a range of priority levels Low .. High. If no quantum is set for a Round Robin priority level, Default_Quantum is used. 6/2

{*AI95-00355-01*} The function Actual_Quantum returns the actual quantum used by the implementation for the priority level Pri. 7/2

{*AI95-00355-01*} {*AI05-0264-1*} The function Is_Round_Robin returns True if priority Pri is covered by task dispatching policy Round_Robin_Within_Priorities; otherwise, it returns False. 8/3

{*AI95-00355-01*} A call of Actual_Quantum or Set_Quantum raises exception Dispatching.Dispatching_Policy_Error if a predefined policy other than Round_Robin_Within_Priorities applies to the specified priority or any of the priorities in the specified range. 9/2

{*AI95-00355-01*} For Round_Robin_Within_Priorities, the dispatching rules for FIFO_Within_Priorities apply with the following additional rules: 10/2

- When a task is added or moved to the tail of the ready queue for its base priority, it has an execution time budget equal to the quantum for that priority level. This will also occur when a blocked task becomes executable again. 11/2
- When a task is preempted (by a higher priority task) and is added to the head of the ready queue for its priority level, it retains its remaining budget. 12/2
- While a task is executing, its budget is decreased by the amount of execution time it uses. The accuracy of this accounting is the same as that for execution time clocks (see D.14). 13/2

  Ramification: Note that this happens even when the task is executing at a higher, inherited priority, and even if that higher priority is dispatched by a different policy than round robin. 13.a/2
- When a task has exhausted its budget and is without an inherited priority (and is not executing within a protected operation), it is moved to the tail of the ready queue for its priority level. This is a task dispatching point. 14/2

  Ramification: In this case, it will be given a budget as described in the first bullet. 14.a/2

  The rules for FIFO_Within_Priority (to which these bullets are added) say that a task that has its base priority set to a Round Robin priority is moved to the tail of the ready queue for its new priority level, and then will be given a budget as described in the first bullet. That happens whether or not the task's original base priority was a Round Robin priority. 14.b/2

Implementation Requirements

15/2 {*AI95-00333-01*} {*AI95-00355-01*} An implementation shall allow, for a single partition, both the task dispatching policy to be specified as Round_Robin_Within_Priorities and also the locking policy (see D.3) to be specified as Ceiling_Locking.

15.a/2 **Reason:** This is the preferred combination of the Round_Robin_Within_Priorities policy with a locking policy, and we want that combination to be portable.

Documentation Requirements

16/2 {*AI95-00355-01*} An implementation shall document the quantum values supported.

16.a.1/2 **Documentation Requirement:** The quantum values supported for round robin dispatching.

17/2 {*AI95-00355-01*} An implementation shall document the accuracy with which it detects the exhaustion of the budget of a task.

17.a.1/2 **Documentation Requirement:** The accuracy of the detection of the exhaustion of the budget of a task for round robin dispatching.

18/5 NOTE 1 {*AI95-00355-01*} {*AI12-0442-1*} Due to implementation constraints, the quantum value returned by Actual_Quantum can differ from that set with Set_Quantum.

19/2 NOTE 2 {*AI95-00355-01*} A task that executes continuously with an inherited priority will not be subject to round robin dispatching.

Extensions to Ada 95

19.a/2 {*AI95-00355-01*} Policy Round_Robin_Within_Priorities and package Dispatching.Round_Robin are new.

D.2.6 Earliest Deadline First Dispatching

1/5 {*AI95-00357-01*} {*AI12-0439-1*} The deadline of a task is an indication of the urgency of the task; it represents a point on an ideal physical time line. The deadline can affect how resources are allocated to the task.

2/5 {*AI95-00357-01*} {*AI05-0229-1*} {*AI05-0299-1*} {*AI12-0230-1*} [This subclause presents Dispatching.EDF, a package for representing the deadline of a task and a dispatching policy that defines Earliest Deadline First (EDF) dispatching. The Relative_Deadline aspect is provided to assign an initial deadline to a task. A configuration pragma Generate_Deadlines is provided to specify that a task's deadline is recomputed whenever it is made ready.]

2.a/5 *This paragraph was deleted.*{*AI05-0229-1*} {*AI12-0230-1*}

Language Design Principles

2.b/5 *This paragraph was deleted.*{*AI95-00357-01*} {*AI05-0299-1*} {*AI12-0230-1*}

Paragraphs 3 through 6 were moved to Annex J, "Obsolescent Features".

Static Semantics

7/5 {*AI95-00357-01*} {*AI12-0230-1*} The *policy_*identifier EDF_Within_Priorities is a task dispatching policy.

{*AI95-00357-01*} The following language-defined library package exists: 8/2

```
{AI12-0230-1} {AI12-0241-1} {AI12-0302-1} with Ada.Real_Time;                    9/5
with Ada.Task_Identification;
package Ada.Dispatching.EDF
  with Nonblocking, Global => in out synchronized is
  subtype Deadline is Ada.Real_Time.Time;
  subtype Relative_Deadline is Ada.Real_Time.Time_Span;
  Default_Deadline : constant Deadline :=
              Ada.Real_Time.Time_Last;
  Default_Relative_Deadline : constant Relative_Deadline :=
              Ada.Real_Time.Time_Span_Last;
  procedure Set_Deadline
     (D : in Deadline;
      T : in Ada.Task_Identification.Task_Id :=
      Ada.Task_Identification.Current_Task);
  function Get_Deadline
     (T : Ada.Task_Identification.Task_Id :=
      Ada.Task_Identification.Current_Task) return Deadline;
  procedure Set_Relative_Deadline
     (D : in Relative_Deadline;
      T : in Ada.Task_Identification.Task_Id :=
      Ada.Task_Identification.Current_Task);
  function Get_Relative_Deadline
     (T : Ada.Task_Identification.Task_Id :=
      Ada.Task_Identification.Current_Task)
      return Relative_Deadline;
  procedure Delay_Until_And_Set_Deadline
     (Delay_Until_Time : in Ada.Real_Time.Time;
      Deadline_Offset : in Ada.Real_Time.Time_Span)
     with Nonblocking => False;
  function Get_Last_Release_Time
     (T : Ada.Task_Identification.Task_Id :=
      Ada.Task_Identification.Current_Task)
      return Ada.Real_Time.Time;
end Ada.Dispatching.EDF;
```

{*AI05-0229-1*} {*AI12-0230-1*} For a subprogram, a task type (including the anonymous type of a single_task_declaration), or a protected type (including the anonymous type of a single_protected_declaration), the following language-defined representation aspect may be specified: 9.1/5

Relative_Deadline 9.2/3

The aspect Relative_Deadline is an expression, which shall be of type Real_Time.Time_Span.

Aspect Description for Relative_Deadline: Task or protected type parameter used in Earliest Deadline First Dispatching. 9.a/5

{*AI12-0230-1*} The form of pragma Generate_Deadlines is as follows: 9.3/5

pragma Generate_Deadlines; 9.4/5

{*AI12-0230-1*} The Generate_Deadlines pragma is a configuration pragma. 9.5/5

Legality Rules

{*AI05-0229-1*} {*AI12-0230-1*} The Relative_Deadline aspect shall not be specified on a task or protected interface type. If the Relative_Deadline aspect is specified for a subprogram, the aspect_definition shall be a static expression. 9.6/5

Post-Compilation Rules

{*AI95-00357-01*} {*AI12-0230-1*} If the EDF_Within_Priorities policy is specified for a partition, then the Ceiling_Locking policy (see D.3) shall also be specified for the partition. 10/5

11/5 {*AI95-00357-01*} {*AI12-0230-1*} If the EDF_Within_Priorities policy appears in a Priority_Specific_Dispatching pragma (see D.2.2) in a partition, then the Ceiling_Locking policy (see D.3) shall also be specified for the partition.

11.a/5 **Reason:** Unlike the other language-defined dispatching policies, the semantic description of EDF_Within_Priorities assumes Ceiling_Locking (and a ceiling priority) in order to make the mapping between deadlines and priorities work. Thus, we require both policies to be specified if EDF is used in the partition.

Dynamic Semantics

12/3 {*AI95-00357-01*} {*AI05-0229-1*} The Relative_Deadline aspect has no effect if it is specified for a subprogram other than the main subprogram.

12.1/5 {*AI12-0230-1*} If pragma Generate_Deadlines is in effect, the deadline of a task is recomputed each time it becomes ready. The new deadline is the value of Real_Time.Clock at the time the task is added to a ready queue plus the value returned by Get_Relative_Deadline.

13/5 {*AI95-00357-01*} {*AI05-0229-1*} {*AI12-0230-1*} The initial absolute deadline for a task with a specified Relative_Deadline is the result of adding the value returned by a call of Real_Time.Clock to the value of the expression specified as the Relative_Deadline aspect, where this entire computation, including the call of Real_Time.Clock, is performed between task creation and the start of its activation. If the aspect Relative_Deadline is not specified, then the initial absolute deadline of a task is the value of Default_Deadline (Ada.Real_Time.Time_Last). The environment task is also given an initial deadline by this rule, using the value of the Relative_Deadline aspect of the main subprogram (if any).

13.a/2 **Proof:** The environment task is a normal task by 10.2, so of course this rule applies to it.

13.1/5 {*AI12-0230-1*} The effect of specifying a Relative_Deadline aspect for a protected type or single_protected_declaration is discussed in D.3.

14/5 {*AI95-00357-01*} {*AI12-0230-1*} A task has both an *active* and a *base* absolute deadline. These are the same except when the task is inheriting a relative deadline during activation or a rendezvous (see below) or within a protected action (see D.3). The procedure Set_Deadline changes the (base) absolute deadline of the task to D. The function Get_Deadline returns the (base) absolute deadline of the task.

14.1/5 {*AI12-0230-1*} The procedure Set_Relative_Deadline changes the relative deadline of the task to D. The function Get_Relative_Deadline returns the relative deadline of the task.

14.2/5 {*AI12-0230-1*} The function Get_Last_Release_Time returns the time, as provided by Real_Time.Clock, when the task was last made ready (that is, was added to a ready queue).

15/5 {*AI95-00357-01*} {*AI12-0230-1*} The procedure Delay_Until_And_Set_Deadline delays the calling task until time Delay_Until_Time. When the task becomes ready again it will have deadline `Delay_Until_Time + Deadline_Offset`.

16/5 {*AI95-00357-01*} {*AI12-0230-1*} On a system with a single processor, the setting of the deadline of a task to the new value occurs immediately at the first point that is outside the execution of a protected action. If the task is currently on a ready queue it is removed and re-entered onto the ready queue determined by the rules defined below.

17/5 {*AI95-00357-01*} {*AI12-0230-1*} When EDF_Within_Priorities is specified for a priority, the ready queue for that priority is ordered by deadline. The task at the head of a queue is the one with the earliest deadline.

18/5 {*AI95-00357-01*} {*AI12-0230-1*} A task dispatching point occurs for the currently running task *T* to which policy EDF_Within_Priorities applies:

19/5 - {*AI12-0230-1*} when a change to the base (absolute) deadline of *T* occurs;

- *This paragraph was deleted.*{*AI12-0230-1*} 20/5
- {*AI12-0230-1*} there is a nonempty ready queue for that processor with a higher priority than the active priority of the running task; 21/5
- {*AI12-0230-1*} there is a ready task with the same priority as *T* but with an earlier absolute deadline. 21.1/5

{*AI12-0230-1*} In these cases, the currently running task is said to be preempted and is returned to the ready queue for its active priority, at a position determined by its active (absolute) deadline. 22/5

Paragraphs 23 through 27 were deleted.

{*AI95-00357-01*} {*AI12-0230-1*} When the setting of the base priority of a ready task takes effect and the new priority is specified as EDF_Within_Priorities, the task is added to the ready queue, at a position determined by its active deadline. 28/5

{*AI95-00357-01*} For all the operations defined in Dispatching.EDF, Tasking_Error is raised if the task identified by T has terminated. Program_Error is raised if the value of T is Null_Task_Id. 29/2

{*AI12-0230-1*} If two tasks with priority designated as EDF_Within_Priorities rendezvous then the deadline for the execution of the accept statement is the earlier of the deadlines of the two tasks. 29.1/5

{*AI12-0230-1*} During activation, a task being activated inherits the deadline that its activator (see 9.2) had at the time the activation was initiated. 29.2/5

Paragraph 30 was deleted.

Erroneous Execution

{*AI95-00357-01*} If a value of Task_Id is passed as a parameter to any of the subprograms of this package and the corresponding task object no longer exists, the execution of the program is erroneous. 31/2

Documentation Requirements

{*AI95-00357-01*} On a multiprocessor, the implementation shall document any conditions that cause the completion of the setting of the deadline of a task to be delayed later than what is specified for a single processor. 32/2

Documentation Requirement: Any conditions that cause the completion of the setting of the deadline of a task to be delayed for a multiprocessor. 32.a.1/2

NOTE {*AI95-00357-01*} {*AI05-0264-1*} {*AI12-0230-1*} If two distinct priorities are specified to have policy EDF_Within_Priorities, then tasks from the higher priority always run before tasks of the lower priority, regardless of deadlines. 33/5

This paragraph was deleted.{*AI95-00357-01*} {*AI12-0230-1*} 34/5

Implementation Note: {*AI95-00357-01*} An implementation may support additional dispatching policies by replacing absolute deadline with an alternative measure of urgency. 34.a/2

Extensions to Ada 95

{*AI95-00357-01*} Policy EDF_Across_Priorities and package Dispatching.EDF are new. 34.b/2

Extensions to Ada 2005

{*AI05-0229-1*} Aspect Relative_Deadline is new; pragma Relative_Deadline is now obsolescent. 34.c/3

Wording Changes from Ada 2005

{*AI05-0055-1*} **Correction:** Corrected definition of active priority to avoid deadline inversion in an unusual case. 34.d/3

Incompatibilities With Ada 2012

34.e/5 {*AI12-0005-1*} {*AI12-0230-1*} The policy EDF_Across_Priorities was replaced by EDF_Within_Priorities. A program using EDF_Across_Priorities could fail to compile. However, we are not aware of any implementations of EDF_Across_Priorities, so it seems unlikely that any such programs exist outside of books and papers.

D.3 Priority Ceiling Locking

1/3 {*AI05-0299-1*} [This subclause specifies the interactions between priority task scheduling and protected object ceilings. This interaction is based on the concept of the *ceiling priority* of a protected object.]

Syntax

2 The form of a pragma Locking_Policy is as follows:

3 **pragma** Locking_Policy(*policy*_identifier);

Legality Rules

4 The *policy*_identifier shall either be Ceiling_Locking or an implementation-defined identifier.

4.a **Implementation defined:** Implementation-defined *policy*_identifiers allowed in a pragma Locking_Policy.

Post-Compilation Rules

5 A Locking_Policy pragma is a configuration pragma.

Dynamic Semantics

6/2 {*8652/0073*} {*AI95-00091-01*} {*AI95-00327-01*} [A locking policy specifies the details of protected object locking. All protected objects have a priority. The locking policy specifies the meaning of the priority of a protected object, and the relationships between these priorities and task priorities. In addition, the policy specifies the state of a task when it executes a protected action, and how its active priority is affected by the locking.] The *locking policy* is specified by a Locking_Policy pragma. For implementation-defined locking policies, the meaning of the priority of a protected object is implementation defined. If no Locking_Policy pragma applies to any of the program units comprising a partition, the locking policy for that partition, as well as the meaning of the priority of a protected object, are implementation defined.

6.a/2 **Implementation defined:** The locking policy if no Locking_Policy pragma applies to any unit of a partition.

6.1/3 {*AI95-00327-01*} {*AI05-0229-1*} The expression specified for the Priority or Interrupt_Priority aspect (see D.1) is evaluated as part of the creation of the corresponding protected object and converted to the subtype System.Any_Priority or System.Interrupt_Priority, respectively. The value of the expression is the initial priority of the corresponding protected object. If no Priority or Interrupt_Priority aspect is specified for a protected object, the initial priority is specified by the locking policy.

7 There is one predefined locking policy, Ceiling_Locking; this policy is defined as follows:

8/3 - {*AI95-00327-01*} {*AI05-0229-1*} Every protected object has a *ceiling priority*, which is determined by either a Priority or Interrupt_Priority aspect as defined in D.1, or by assignment to the Priority attribute as described in D.5.2. The ceiling priority of a protected object (or ceiling, for short) is an upper bound on the active priority a task can have when it calls protected operations of that protected object.

9/2 - {*AI95-00327-01*} The initial ceiling priority of a protected object is equal to the initial priority for that object.

10/4 - {*AI95-00327-01*} {*AI05-0229-1*} {*AI12-0051-1*} If an Interrupt_Handler or Attach_Handler aspect (see C.3.1) is specified for a protected subprogram of a protected type that does not have

either the Priority or Interrupt_Priority aspect specified, the initial priority of protected objects of that type is implementation defined, but in the range of the subtype System.Interrupt_Priority.

Implementation defined: Default ceiling priorities. 10.a

- {*AI95-00327-01*} {*AI05-0229-1*} If neither aspect Priority nor Interrupt_Priority is specified for a protected type, and no protected subprogram of the type has aspect Interrupt_Handler or Attach_Handler specified, then the initial priority of the corresponding protected object is System.Priority'Last. 11/3
- While a task executes a protected action, it inherits the ceiling priority of the corresponding protected object. 12
- When a task calls a protected operation, a check is made that its active priority is not higher than the ceiling of the corresponding protected object; Program_Error is raised if this check fails. 13

{*AI12-0230-1*} {*AI12-0404-1*} If the task dispatching policy specified for the ceiling priority of a protected object is EDF_Within_Priorities, the following additional rules apply: 13.1/5

- Every protected object has a *relative deadline*, which is determined by a Relative_Deadline aspect as defined in D.2.6, or by assignment to the Relative_Deadline attribute as described in D.5.2. The relative deadline of a protected object represents a lower bound on the relative deadline a task may have when it calls a protected operation of that protected object. 13.2/5
- If aspect Relative_Deadline is not specified for a protected type then the initial relative deadline of the corresponding protected object is Ada.Real_Time.Time_Span_Zero. 13.3/5
- While a task executes a protected action on a protected object *P*, it inherits the relative deadline of *P*. In this case, let *DF* be 'now' ('now' is obtained via a call on Ada.Real_Time.Clock at the start of the action) plus the deadline floor of *P*. If the active deadline of the task is later than *DF*, its active deadline is reduced to *DF*[; the active deadline is unchanged otherwise]. 13.4/5
- When a task calls a protected operation, a check is made that its active deadline minus its last release time is not less than the relative deadline of the corresponding protected object; Program_Error is raised if this check fails. 13.5/5

Bounded (Run-Time) Errors

{*AI95-00327-01*} {*AI12-0230-1*} Following any change of priority, it is a bounded error for the active priority of any task with a call queued on an entry of a protected object to be higher than the ceiling priority of the protected object. In this case one of the following applies: 13.6/5

- {*AI12-0404-1*} at any time prior to executing the entry body, Program_Error is raised in the calling task; 13.7/5
- {*AI12-0404-1*} when the entry is open, the entry body is executed at the ceiling priority of the protected object; 13.8/5
- {*AI12-0404-1*} when the entry is open, the entry body is executed at the ceiling priority of the protected object and then Program_Error is raised in the calling task; or 13.9/5
- {*AI12-0404-1*} when the entry is open, the entry body is executed at the ceiling priority of the protected object that was in effect when the entry call was queued. 13.10/5

Ramification: Note that the error is “blamed” on the task that did the entry call, not the task that changed the priority of the task or protected object. This seems to make sense for the case of changing the priority of a task blocked on a call, since if the Set_Priority had happened a little bit sooner, before the task queued a call, the entry-calling task would get the error. Similarly, there is no reason not to raise the priority of a task that is executing in an abortable_part, so long as its priority is lowered before it gets to the end and needs to cancel the call. The priority might need to be lowered to allow it to remove the call from the entry queue, in order to avoid violating the ceiling. This seems relatively harmless, since there is an error, and the task is about to start raising an exception anyway. 13.a.1/2

Implementation Permissions

14 The implementation is allowed to round all ceilings in a certain subrange of System.Priority or System.Interrupt_Priority up to the top of that subrange, uniformly.

14.a **Discussion:** For example, an implementation might use Priority'Last for all ceilings in Priority, and Interrupt_Priority'Last for all ceilings in Interrupt_Priority. This would be equivalent to having two ceiling priorities for protected objects, “nonpreemptible” and “noninterruptible”, and is an allowed behavior.

14.b Note that the implementation cannot choose a subrange that crosses the boundary between normal and interrupt priorities.

15/5 {*AI95-00256-01*} {*AI12-0444-1*} Implementations are allowed to define other locking policies, but are not required to support specifying more than one locking policy per partition.

16 [Since implementations are allowed to place restrictions on code that runs at an interrupt-level active priority (see C.3.1 and D.2.1), the implementation may implement a language feature in terms of a protected object with an implementation-defined ceiling, but the ceiling shall be no less than Priority'Last.]

16.a **Implementation defined:** The ceiling of any protected object used internally by the implementation.

16.b **Proof:** This permission follows from the fact that the implementation can place restrictions on interrupt handlers and on any other code that runs at an interrupt-level active priority.

16.c The implementation might protect a storage pool with a protected object whose ceiling is Priority'Last, which would cause allocators to fail when evaluated at interrupt priority. Note that the ceiling of such an object has to be at least Priority'Last, since there is no permission for allocators to fail when evaluated at a noninterrupt priority.

Implementation Advice

17 The implementation should use names that end with “_Locking” for implementation-defined locking policies.

17.a/2 **Implementation Advice:** Names that end with “_Locking” should be used for implementation-defined locking policies.

18 NOTE 1 While a task executes in a protected action, it can be preempted only by tasks whose active priorities are higher than the ceiling priority of the protected object.

19 NOTE 2 If a protected object has a ceiling priority in the range of Interrupt_Priority, certain interrupts are blocked while protected actions of that object execute. In the extreme, if the ceiling is Interrupt_Priority'Last, all blockable interrupts are blocked during that time.

20/5 NOTE 3 {*AI12-0447-1*} As described in C.3.1, whenever an interrupt is handled by one of the protected procedures of a protected object, a check is made that its ceiling priority is in the Interrupt_Priority range.

21/5 NOTE 4 {*AI12-0442-1*} When specifying the ceiling of a protected object, a correct value is one that is at least as high as the highest active priority at which tasks can be executing when they call protected operations of that object. In determining this value the following factors, which can affect active priority, are relevant: the effect of Set_Priority, nested protected operations, entry calls, task activation, and other implementation-defined factors.

22 NOTE 5 Attaching a protected procedure whose ceiling is below the interrupt hardware priority to an interrupt causes the execution of the program to be erroneous (see C.3.1).

23 NOTE 6 On a single processor implementation, the ceiling priority rules guarantee that there is no possibility of deadlock involving only protected subprograms (excluding the case where a protected operation calls another protected operation on the same protected object).

Extensions to Ada 95

23.a/2 {*AI95-00327-01*} All protected objects now have a priority, which is the value of the Priority attribute of D.5.2. How this value is interpreted depends on the locking policy; for instance, the ceiling priority is derived from this value when the locking policy is Ceiling_Locking.

Wording Changes from Ada 95

23.b/2 {*8652/0073*} {*AI95-00091-01*} **Corrigendum:** Corrected the wording to reflect that pragma Locking_Policy cannot be inside of a program unit.

{*AI95-00256-01*} Clarified that an implementation need support only one locking policy (of any kind, language-defined or otherwise) per partition. 23.c/2

{*AI95-00327-01*} The bounded error for the priority of a task being higher than the ceiling of an object it is currently in was moved here from D.5, so that it applies no matter how the situation arises. 23.d/2

Wording Changes from Ada 2005

{*AI05-0229-1*} Revised to use aspects Priority and Interrupt_Priority as pragmas Priority and Interrupt_Priority are now obsolescent. 23.e/3

Extensions to Ada 2012

{*AI12-0230-1*} All protected objects now have a relative deadline, which is the value of the Relative_Deadline attribute of D.5.2. How this value is interpreted depends on the locking policy. 23.f/5

Wording Changes from Ada 2012

{*AI12-0051-1*} **Corrigendum:** Clarified that the Priority aspect can be used to set the initial ceiling priority of a protected object that contains an interrupt handler. 23.g/4

D.4 Entry Queuing Policies

{*8652/0074*} {*AI95-00068-01*} {*AI05-0299-1*} {*AI12-0324-1*} [This subclause specifies a mechanism for a user to choose an entry *queuing policy*. It also defines three such policies. Other policies are implementation defined.] 1/5

Implementation defined: Implementation-defined queuing policies. 1.a

Syntax

The form of a pragma Queuing_Policy is as follows: 2

pragma Queuing_Policy(*policy*_identifier); 3

Legality Rules

{*AI12-0183-1*} The *policy*_identifier shall be either FIFO_Queuing, Ordered_FIFO_Queuing, Priority_Queuing or an implementation-defined identifier. 4/5

Post-Compilation Rules

A Queuing_Policy pragma is a configuration pragma. 5

Dynamic Semantics

[A *queuing policy* governs the order in which tasks are queued for entry service, and the order in which different entry queues are considered for service.] The queuing policy is specified by a Queuing_Policy pragma. 6

Ramification: The queuing policy includes entry queuing order, the choice among open alternatives of a selective_accept, and the choice among queued entry calls of a protected object when more than one entry_barrier condition is True. 6.a

{*AI95-00355-01*} {*AI12-0163-1*} {*AI12-0183-1*} Three queuing policies, FIFO_Queuing, Ordered_FIFO_Queuing, and Priority_Queuing, are language defined. If no Queuing_Policy pragma applies to any of the program units comprising the partition, the queuing policy for that partition is FIFO_Queuing. The rules for the FIFO_Queuing policy are specified in 9.5.3 and 9.7.1. 7/5

{*AI12-0163-1*} The Ordered_FIFO_Queuing policy is defined as follows: 7.1/5

- Calls are selected on a given entry queue in order of arrival. 7.2/5

7.3/5 • When more than one condition of an entry_barrier of a protected object becomes True, and more than one of the respective queues is nonempty, the call that arrived first is selected.

7.4/5 • If the expiration time of two or more open delay_alternatives is the same and no other accept_alternatives are open, the sequence_of_statements of the delay_alternative that is first in textual order in the selective_accept is executed.

7.5/5 • When more than one alternative of a selective_accept is open and has queued calls, the alternative whose queue has the call that arrived first is selected.

7.a/5 **Implementation Note:** A possible implementation for this policy would be to assign a sequence number to each queued entry call, where the sequence number is incremented globally across all queues associated with the protected object or selective_accept.

7.b/5 **Reason:** It would have been marginally easier to use textual order for the case when multiple queues are selectable. But textual order can lead to unfair queue servicing, since the queues in earlier textual order will end up starving the later ones if calls arrive fast enough. Applying arrival first as the selector provides fairness for this policy.

8 The Priority_Queuing policy is defined as follows:

9 • The calls to an entry [(including a member of an entry family)] are queued in an order consistent with the priorities of the calls. The *priority of an entry call* is initialized from the active priority of the calling task at the time the call is made, but can change later. Within the same priority, the order is consistent with the calling (or requeuing, or priority setting) time (that is, a FIFO order).

10/1 • {*8652/0075*} {*AI95-00205-01*} After a call is first queued, changes to the active priority of a task do not affect the priority of the call, unless the base priority of the task is set while the task is blocked on an entry call.

11 • When the base priority of a task is set (see D.5), if the task is blocked on an entry call, and the call is queued, the priority of the call is updated to the new active priority of the calling task. This causes the call to be removed from and then reinserted in the queue at the new active priority.

11.a **Reason:** A task is blocked on an entry call if the entry call is simple, conditional, or timed. If the call came from the triggering_statement of an asynchronous_select, or a requeue thereof, then the task is not blocked on that call; such calls do not have their priority updated. Thus, there can exist many queued calls from a given task (caused by many nested ATC's), but a task can be blocked on only one call at a time.

11.b A previous version of Ada 9X required queue reordering in the asynchronous_select case as well. If the call corresponds to a “synchronous” entry call, then the task is blocked while queued, and it makes good sense to move it up in the queue if its priority is raised.

11.c However, if the entry call is “asynchronous”, that is, it is due to an asynchronous_select whose triggering_statement is an entry call, then the task is not waiting for this entry call, so the placement of the entry call on the queue is irrelevant to the rate at which the task proceeds.

11.d Furthermore, when an entry is used for asynchronous_selects, it is almost certain to be a “broadcast” entry or have only one caller at a time. For example, if the entry is used to notify tasks of a mode switch, then all tasks on the entry queue would be signaled when the mode changes. Similarly, if it is indicating some interrupting event such as a control-C, all tasks sensitive to the interrupt will want to be informed that the event occurred. Hence, the order on such a queue is essentially irrelevant.

11.e Given the above, it seems an unnecessary semantic and implementation complexity to specify that asynchronous queued calls are moved in response to dynamic priority changes. Furthermore, it is somewhat inconsistent, since the call was originally queued based on the active priority of the task, but dynamic priority changes are changing the base priority of the task, and only indirectly the active priority. We say explicitly that asynchronous queued calls are not affected by normal changes in active priority during the execution of an abortable_part. Saying that, if a change in the base priority affects the active priority, then we do want the calls reordered, would be inconsistent. It would also require the implementation to maintain a readily accessible list of all queued calls which would not otherwise be necessary.

11.f Several rules were removed or simplified when we changed the rules so that calls due to asynchronous_selects are never moved due to intervening changes in active priority, be they due to protected actions, some other priority inheritance, or changes in the base priority.

12 • When more than one condition of an entry_barrier of a protected object becomes True, and more than one of the respective queues is nonempty, the call with the highest priority is selected. If more than one such call has the same priority, the call that is queued on the entry whose

declaration is first in textual order in the protected_definition is selected. For members of the same entry family, the one with the lower family index is selected.

- If the expiration time of two or more open delay_alternatives is the same and no other accept_alternatives are open, the sequence_of_statements of the delay_alternative that is first in textual order in the selective_accept is executed. 13
- When more than one alternative of a selective_accept is open and has queued calls, an alternative whose queue has the highest-priority call at its head is selected. If two or more open alternatives have equal-priority queued calls, then a call on the entry in the accept_alternative that is first in textual order in the selective_accept is selected. 14

Implementation Permissions

{*AI95-00256-01*} {*AI12-0444-1*} Implementations are allowed to define other queuing policies, but are not required to support specifying more than one queuing policy per partition. 15/5

Discussion: {*8652/0116*} {*AI95-00069-01*} {*AI95-00256-01*} This rule is really redundant, as 10.1.5 allows an implementation to limit the use of configuration pragmas to an empty environment. In that case, there would be no way to have multiple policies in a partition. 15.a.1/2

{*AI95-00188-02*} Implementations are allowed to defer the reordering of entry queues following a change of base priority of a task blocked on the entry call if it is not practical to reorder the queue immediately. 15.1/2

Reason: Priority change is immediate, but the effect of the change on entry queues can be deferred. That is necessary in order to implement priority changes on top of a non-Ada kernel. 15.a.2/2

Discussion: The reordering should occur as soon as the blocked task can itself perform the reinsertion into the entry queue. 15.a.3/2

Implementation Advice

The implementation should use names that end with "_Queuing" for implementation-defined queuing policies. 16

Implementation Advice: Names that end with "_Queuing" should be used for implementation-defined queuing policies. 16.a/2

Static Semantics

{*AI12-0164-1*} For a task type (including the anonymous type of a single_task_declaration), protected type (including the anonymous type of a single_protected_declaration), or an entry_declaration, the following language-defined representation aspect may be specified: 17/5

Max_Entry_Queue_Length 18/5

The type of aspect Max_Entry_Queue_Length is Integer.

Aspect Description for Max_Entry_Queue_Length: The maximum entry queue length for a task type, protected type, or entry. 18.a/5

If directly specified, the aspect_definition shall be a static expression no less than -1. If not specified, the aspect has value -1 (representing no additional restriction on queue length). 19/5

Legality Rules

{*AI12-0164-1*} {*AI12-0388-1*} If the Max_Entry_Queue_Length aspect for a type has a nonnegative value, the Max_Entry_Queue_Length aspect for every individual entry of that type shall not be greater than the value of the aspect for the type. The Max_Entry_Queue_Length aspect of a type is nonoverridable (see 13.1.1). 20/5

Ramification: Aspect Max_Entry_Queue_Length can specify less than the partition-wide or type-wide default, but it can't expand the length of a queue. 20.a/5

Post-Compilation Rules

21/5 {*AI12-0164-1*} If a restriction Max_Entry_Queue_Length applies to a partition, any value specified for the Max_Entry_Queue_Length aspect specified for the declaration of a type or entry in the partition shall not be greater than the value of the restriction.

21.a/5 **Ramification:** 13.12(6) says that the restriction value has to be static, so this is statically checkable. But the restriction does not have to be in the same compilation as the aspect, so the check cannot, in general, be done until link time.

Dynamic Semantics

22/5 {*AI12-0164-1*} If a nonconfirming value is specified for Max_Entry_Queue_Length for a type, and an entry call or requeue would cause the queue for any entry of the type to become longer than the specified value, then Program_Error is raised at the point of the call or requeue.

23/5 {*AI12-0164-1*} If a nonconfirming value is specified for Max_Entry_Queue_Length for an entry, and an entry call or requeue would cause the queue for an entry to become longer than the specified value, then Program_Error is raised at the point of the call or requeue.

Wording Changes from Ada 95

23.a/2 {*8652/0074*} {*AI95-00068-01*} **Corrigendum:** Corrected the number of queuing policies defined.

23.b/2 {*8652/0075*} {*AI95-00205-01*} **Corrigendum:** Corrected so that a call of Set_Priority in an abortable part does not change the priority of the triggering entry call.

23.c/2 {*AI95-00188-02*} Added a permission to defer queue reordering when the base priority of a task is changed. This is a counterpart to stronger requirements on the implementation of priority change.

23.d/2 {*AI95-00256-01*} Clarified that an implementation need support only one queuing policy (of any kind, language-defined or otherwise) per partition.

23.e/2 {*AI95-00355-01*} Fixed wording to make clear that pragma never appears inside of a unit; rather it “applies to” the unit.

Extensions to Ada 2012

23.f/5 {*AI12-0163-1*} Defined the new queuing policy Ordered_FIFO_Queuing.

23.g/5 {*AI12-0164-1*} Defined the new aspect Max_Entry_Queue_Length.

D.4.1 Admission Policies

1/5 {*AI12-0276-1*} [This subclause specifies a mechanism for a user to choose an admission policy. It also defines one such policy. Other policies are implementation defined.]

1.a.1/5 **Implementation defined:** Implementation-defined admission policies.

Syntax

2/5 {*AI12-0276-1*} The form of a pragma Admission_Policy is as follows:

3/5 **pragma** Admission_Policy (*policy*_identifier);

Legality Rules

4/5 {*AI12-0276-1*} The *policy*_identifier shall be either FIFO_Spinning or an implementation-defined identifier.

Post-Compilation Rules

5/5 {*AI12-0276-1*} An Admission_Policy pragma is a configuration pragma.

Dynamic Semantics

{*AI12-0276-1*} An admission policy governs the order in which competing tasks are evaluated for acquiring the execution resource associated with a protected object. The admission policy is specified by an Admission_Policy pragma. 6/5

{*AI12-0276-1*} One admission policy, FIFO_Spinning, is language defined. If FIFO_Spinning is in effect, and starting a protected action on a protected object involves busy-waiting, then calls are selected for acquiring the execution resource of the protected object in the order in which the busy-wait was initiated; otherwise the FIFO_Spinning policy has no effect. If no Admission_Policy pragma applies to any of the program units in the partition, the admission policy for that partition is implementation defined. 7/5

Discussion: {*AI12-0005-1*} Busy-waiting might be used for protected objects that can be called from tasks running on other processors than the one the protected object is on. It is unnecessary if all of the tasks that can call a protected object are on the same processor as the object; in particular, it would not be used on a monoprocessor. Aspect CPU (see D.16) can be used to ensure that busy-waiting is not needed. 7.a/5

Implementation Note: A possible implementation for this policy would be to apply the abstraction of a ticketing system by assigning two sequence number values to each protected object. One sequence number represents the next available ticket number, and the other sequence number represents the ticket number currently being serviced by the protected object. The next available ticket number is incremented and assigned to a task when the task initiates a busy-wait for acquiring the execution resource associated with the protected object. The ticket number currently being serviced is incremented when a task releases this execution resource. As part of acquiring the execution resource, a task busy-waits until its assigned ticket number equals the protected object's value for the ticket number currently being serviced. While a task busy-waits, it monitors the active priority of the protected object in order to inherit any modifications to the protected object's active priority. 7.b/5

Implementation Permissions

{*AI12-0276-1*} {*AI12-0444-1*} Implementations are allowed to define other admission policies, but are not required to support specifying more than one admission policy per partition. 8/5

Discussion: This rule is in fact redundant, as 10.1.5 allows an implementation to limit the use of configuration pragmas to an empty environment. In that case, there would be no way to have multiple policies in a partition. 8.a/5

Extensions to Ada 2012

{*AI12-0276-1*} Admission Policies and the specific policy FIFO_Spinning are new. 8.b/5

D.5 Dynamic Priorities

{*AI95-00327-01*} {*AI05-0299-1*} [This subclause describes how the priority of an entity can be modified or queried at run time.] 1/3

Wording Changes from Ada 95

{*AI95-00327-01*} {*AI05-0299-1*} This subclause is turned into two subclauses. This subclause introduction is new. 1.a/3

D.5.1 Dynamic Priorities for Tasks

{*AI05-0299-1*} [This subclause describes how the base priority of a task can be modified or queried at run time.] 1/3

Static Semantics

The following language-defined library package exists: 2

```
{AI95-00362-01} {AI12-0241-1} {AI12-0302-1} with System;                    3/5
with Ada.Task_Identification; -- See C.7.1
package Ada.Dynamic_Priorities
    with Preelaborate, Nonblocking, Global => in out synchronized is
```

```
4          procedure Set_Priority(Priority : in System.Any_Priority;
                                  T : in Ada.Task_Identification.Task_Id :=
                                  Ada.Task_Identification.Current_Task);
5          function Get_Priority (T : Ada.Task_Identification.Task_Id :=
                                  Ada.Task_Identification.Current_Task)
                                  return System.Any_Priority;
6       end Ada.Dynamic_Priorities;
```

Dynamic Semantics

7 The procedure Set_Priority sets the base priority of the specified task to the specified Priority value. Set_Priority has no effect if the task is terminated.

8 The function Get_Priority returns T's current base priority. Tasking_Error is raised if the task is terminated.

8.a **Reason:** There is no harm in setting the priority of a terminated task. A previous version of Ada 9X made this a run-time error. However, there is little difference between setting the priority of a terminated task, and setting the priority of a task that is about to terminate very soon; neither case should be an error. Furthermore, the runtime check is not necessarily feasible to implement on all systems, since priority changes might be deferred due to inter-processor communication overhead, so the error might not be detected until after Set_Priority has returned.

8.b However, we wish to allow implementations to avoid storing "extra" information about terminated tasks. Therefore, we make Get_Priority of a terminated task raise an exception; the implementation need not continue to store the priority of a task that has terminated.

9 Program_Error is raised by Set_Priority and Get_Priority if T is equal to Null_Task_Id.

10/2 {*AI95-00188-02*} On a system with a single processor, the setting of the base priority of a task *T* to the new value occurs immediately at the first point when *T* is outside the execution of a protected action.

10.a/2 **Implementation Note:** {*AI95-00188-02*} The priority change is immediate if the target task is on a delay queue or a ready queue outside of a protected action. However, consider when Set_Priority is called by a task T1 to set the priority of T2, if T2 is blocked, waiting on an entry call queued on a protected object, the entry queue needs to be reordered. Since T1 might have a priority that is higher than the ceiling of the protected object, T1 cannot, in general, do the reordering. One way to implement this is to wake T2 up and have T2 do the work. This is similar to the disentangling of queues that needs to happen when a high-priority task aborts a lower-priority task, which might have a call queued on a protected object with a low ceiling. We have an Implementation Permission in D.4 to allow this implementation. We could have required an immediate priority change if on a ready queue during a protected action, but that would have required extra checks for ceiling violations to meet Bounded (Run-Time) Error requirements of D.3 and potentially could cause a protected action to be abandoned in the middle (by raising Program_Error). That seems bad.

10.b **Reason:** A previous version of Ada 9X made it a run-time error for a high-priority task to set the priority of a lower-priority task that has a queued call on a protected object with a low ceiling. This was changed because:

10.c - The check was not feasible to implement on all systems, since priority changes might be deferred due to inter-processor communication overhead. The calling task would continue to execute without finding out whether the operation succeeded or not.

10.d - The runtime check would tend to cause intermittent system failures — how is the caller supposed to know whether the other task happens to have a queued call at any given time? Consider for example an interrupt that needs to trigger a priority change in some task. The interrupt handler could not safely call Set_Priority without knowing exactly what the other task is doing, or without severely restricting the ceilings used in the system. If the interrupt handler wants to hand the job off to a third task whose job is to call Set_Priority, this won't help, because one would normally want the third task to have high priority.

Paragraph 11 was deleted.

Erroneous Execution

12 If any subprogram in this package is called with a parameter T that specifies a task object that no longer exists, the execution of the program is erroneous.

12.a **Ramification:** Note that this rule overrides the above rule saying that Program_Error is raised on Get_Priority of a terminated task. If the task object still exists, and the task is terminated, Get_Priority raises Program_Error. However, if the task object no longer exists, calling Get_Priority causes erroneous execution.

Documentation Requirements

{*AI95-00188-02*} On a multiprocessor, the implementation shall document any conditions that cause the completion of the setting of the priority of a task to be delayed later than what is specified for a single processor. 12.1/2

Documentation Requirement: Any conditions that cause the completion of the setting of the priority of a task to be delayed for a multiprocessor. 12.a.1/2

Metrics

The implementation shall document the following metric: 13

- The execution time of a call to Set_Priority, for the nonpreempting case, in processor clock cycles. This is measured for a call that modifies the priority of a ready task that is not running (which cannot be the calling one), where the new base priority of the affected task is lower than the active priority of the calling task, and the affected task is not on any entry queue and is not executing a protected operation. 14

Documentation Requirement: The metrics for Set_Priority. 14.a/2

NOTE 1 {*AI95-00321-01*} Setting a task's base priority affects task dispatching. First, it can change the task's active priority. Second, under the FIFO_Within_Priorities policy it always causes the task to move to the tail of the ready queue corresponding to its active priority, even if the new base priority is unchanged. 15/2

NOTE 2 Under the priority queuing policy, setting a task's base priority has an effect on a queued entry call if the task is blocked waiting for the call. That is, setting the base priority of a task causes the priority of a queued entry call from that task to be updated and the call to be removed and then reinserted in the entry queue at the new priority (see D.4), unless the call originated from the triggering_statement of an asynchronous_select. 16

NOTE 3 The effect of two or more Set_Priority calls executed in parallel on the same task is defined as executing these calls in some serial order. 17

Proof: This follows from the general reentrancy requirements stated near the beginning of Annex A, “Predefined Language Environment”. 17.a

NOTE 4 {*AI05-0092-1*} {*AI12-0447-1*} The rule for when Tasking_Error is raised for Set_Priority or Get_Priority is different from the rule for when Tasking_Error is raised on an entry call (see 9.5.3). In particular, the priority of a completed or an abnormal task can be queried so long as the task is not yet terminated, and the priority of a task can be set in any task state (including for terminated tasks). 18/5

NOTE 5 {*AI12-0442-1*} Changing the priorities of a set of tasks can be performed by a series of calls to Set_Priority for each task separately. This can be done reliably within a protected operation that has high enough ceiling priority to guarantee that the operation completes without being preempted by any of the affected tasks. 19/5

Extensions to Ada 95

{*AI95-00188-02*} **Amendment Correction:** Priority changes are now required to be done immediately so long as the target task is not on an entry queue. 19.a/2

{*AI95-00362-01*} Dynamic_Priorities is now Preelaborated, so it can be used in preelaborated units. 19.b/2

Wording Changes from Ada 95

{*AI95-00327-01*} {*AI05-0299-1*} This Ada 95 subclause was moved down a level. The paragraph numbers are the same as those for D.5 in Ada 95. 19.c/3

{*AI95-00321-01*} There is no “standard” policy anymore, so that phrase was replaced by the name of a specific policy in the notes. 19.d/2

{*AI95-00327-01*} The bounded error for the priority of a task being higher than the ceiling of an object it is currently in was moved to D.3, so that it applies no matter how the situation arises. 19.e/2

D.5.2 Dynamic Priorities for Protected Objects

{*AI95-00327-01*} {*AI05-0299-1*} This subclause specifies how the priority of a protected object can be modified or queried at run time. 1/3

Static Semantics

2/5 {*AI95-00327-01*} {*AI12-0230-1*} The following attributes are defined for a prefix P that denotes a protected object:

3/2 P'Priority {*AI95-00327-01*} Denotes a non-aliased component of the protected object P. This component is of type System.Any_Priority and its value is the priority of P. P'Priority denotes a variable if and only if P denotes a variable. A reference to this attribute shall appear only within the body of P.

3.1/5 P'Relative_Deadline
{*AI12-0230-1*} Denotes a non-aliased component of the protected object P. This component is of type Ada.Real_Time.Time_Span and its value is the relative deadline of P. P'Relative_Deadline denotes a variable if and only if P denotes a variable. A reference to this attribute shall appear only within the body of P.

4/5 {*AI95-00327-01*} {*AI12-0230-1*} The initial value of the attribute Priority is determined by the initial value of the priority of the protected object (see D.3)[, and can be changed by an assignment]. The initial value of the attribute Relative_Deadline is determined by the initial value of the relative deadline of the protected object (see D.3)[, and can be changed by an assignment].

Dynamic Semantics

5/3 {*AI95-00327-01*} {*AI05-0264-1*} If the locking policy Ceiling_Locking (see D.3) is in effect, then the ceiling priority of a protected object *P* is set to the value of *P*'Priority at the end of each protected action of *P*.

6/3 {*AI95-00445-01*} {*AI05-0229-1*} If the locking policy Ceiling_Locking is in effect, then for a protected object *P* with either an Attach_Handler or Interrupt_Handler aspect specified for one of its procedures, a check is made that the value to be assigned to *P*'Priority is in the range System.Interrupt_Priority. If the check fails, Program_Error is raised.

Metrics

7/2 {*AI95-00327-01*} The implementation shall document the following metric:

8/2 • The difference in execution time of calls to the following procedures in protected object P:

9/2
```
protected P is
   procedure Do_Not_Set_Ceiling (Pr : System.Any_Priority);
   procedure Set_Ceiling (Pr : System.Any_Priority);
end P;
```

10/2
```
protected body P is
   procedure Do_Not_Set_Ceiling (Pr : System.Any_Priority) is
   begin
      null;
   end;
   procedure Set_Ceiling (Pr : System.Any_Priority) is
   begin
      P'Priority := Pr;
   end;
end P;
```

10.a/2 **Documentation Requirement:** The metrics for setting the priority of a protected object.

11/2 NOTE {*AI95-00327-01*} Since P'Priority is a normal variable, the value following an assignment to the attribute immediately reflects the new value even though its impact on the ceiling priority of P is postponed until completion of the protected action in which it is executed.

Extensions to Ada 95

11.a/2 {*AI95-00327-01*} {*AI95-00445-01*} The ability to dynamically change and query the priority of a protected object is new.

Extensions to Ada 2012

{*AI12-0230-1*} The ability to dynamically change and query the relative deadline of a protected object is new. 11.b/5

D.6 Preemptive Abort

{*AI05-0299-1*} [This subclause specifies requirements on the immediacy with which an aborted construct is completed.] 1/3

Dynamic Semantics

On a system with a single processor, an aborted construct is completed immediately at the first point that is outside the execution of an abort-deferred operation. 2

Documentation Requirements

On a multiprocessor, the implementation shall document any conditions that cause the completion of an aborted construct to be delayed later than what is specified for a single processor. 3

This paragraph was deleted. 3.a/2

Documentation Requirement: On a multiprocessor, any conditions that cause the completion of an aborted construct to be delayed later than what is specified for a single processor. 3.b/2

Metrics

The implementation shall document the following metrics: 4

- The execution time, in processor clock cycles, that it takes for an abort_statement to cause the completion of the aborted task. This is measured in a situation where a task T2 preempts task T1 and aborts T1. T1 does not have any finalization code. T2 shall verify that T1 has terminated, by means of the Terminated attribute. 5
- On a multiprocessor, an upper bound in seconds, on the time that the completion of an aborted task can be delayed beyond the point that it is required for a single processor. 6
- {*AI95-00114-01*} An upper bound on the execution time of an asynchronous_select, in processor clock cycles. This is measured between a point immediately before a task T1 executes a protected operation Pr.Set that makes the condition of an entry_barrier Pr.Wait True, and the point where task T2 resumes execution immediately after an entry call to Pr.Wait in an asynchronous_select. T1 preempts T2 while T2 is executing the abortable part, and then blocks itself so that T2 can execute. The execution time of T1 is measured separately, and subtracted. 7/2
- An upper bound on the execution time of an asynchronous_select, in the case that no asynchronous transfer of control takes place. This is measured between a point immediately before a task executes the asynchronous_select with a nonnull abortable part, and the point where the task continues execution immediately after it. The execution time of the abortable part is subtracted. 8

Documentation Requirement: The metrics for aborts. 8.a/2

Implementation Advice

Even though the abort_statement is included in the list of potentially blocking operations (see 9.5.1), it is recommended that this statement be implemented in a way that never requires the task executing the abort_statement to block. 9

Implementation Advice: The abort_statement should not require the task executing the statement to block. 9.a/2

On a multi-processor, the delay associated with aborting a task on another processor should be bounded; the implementation should use periodic polling, if necessary, to achieve this. 10

10.a/2 **Implementation Advice:** On a multi-processor, the delay associated with aborting a task on another processor should be bounded.

11 NOTE 1 Abortion does not change the active or base priority of the aborted task.

12 NOTE 2 Abortion cannot be more immediate than is allowed by the rules for deferral of abortion during finalization and in protected actions.

D.7 Tasking Restrictions

1/3 {*AI05-0299-1*} [This subclause defines restrictions that can be used with a pragma Restrictions (see 13.12) to facilitate the construction of highly efficient tasking run-time systems.]

Static Semantics

1.1/5 {*AI12-0290-1*} {*AI12-0369-1*} A scalar expression within a protected unit is said to be *pure-barrier-eligible* if it is one of the following:

1.2/5 - a static expression;

1.3/5 - a name that statically names (see 4.9) a scalar subcomponent of the immediately enclosing protected unit;

1.4/5 - a Count attribute_reference whose prefix statically denotes an entry declaration of the immediately enclosing unit;

1.5/5 - a call to a predefined relational operator or boolean logical operator (**and**, **or**, **xor**, **not**), where each operand is pure-barrier-eligible;

1.6/5 - a membership test whose *tested*_simple_expression is pure-barrier-eligible, and whose membership_choice_list meets the requirements for a static membership test (see 4.9);

1.7/5 - a short-circuit control form both of whose operands are pure-barrier-eligible;

1.8/5 - a conditional_expression all of whose conditions, *selecting*_expressions, and *dependent*_expressions are pure-barrier-eligible; or

1.9/5 - a pure-barrier-eligible expression enclosed in parentheses.

2 The following *restriction*_identifiers are language defined:

3/3 {*AI05-0013-1*} {*AI05-0216-1*} No_Task_Hierarchy
No task depends on a master other than the library-level master.

3.a/3 **Ramification:** {*AI05-0216-1*} This is equivalent to saying "no task depends on a master other than the master that is the execution of the body of the environment task of the partition", but it is much easier to understand. This is a post-compilation check, which can be checked at compile-time.

3.b/3 {*AI05-0013-1*} This disallows any function returning an object with a task part or coextension, even if called at the library level, as such a task would temporarily depend on a nested master (the master of the return statement), which is disallowed by this restriction.

4/3 {*8652/0042*} {*AI95-00130-01*} {*AI95-00360-01*} {*AI05-0013-1*} No_Nested_Finalization
Objects of a type that needs finalization (see 7.6) are declared only at library level. If an access type does not have library-level accessibility, then there are no allocators of the type where the type determined by the subtype_mark of the subtype_indication or qualified_expression needs finalization.

4.a/1 *This paragraph was deleted.*{*8652/0042*} {*AI95-00130-01*}

4.b/3 **Ramification:** {*AI05-0013-1*} The second sentence prevents the declaration of objects of access types which would require nested finalization. It also prevents the declarations of coextensions that need finalization in a nested scope. The latter cannot be done by preventing the declaration of the objects, as it is not necessarily known if the coextension type needs finalization (it could be a limited view).

{*AI05-0211-1*} No_Abort_Statements 5/3

There are no abort_statements, and there is no use of a name denoting Task_Identification.Abort_Task.

No_Terminate_Alternatives 6

There are no selective_accepts with terminate_alternatives.

No_Task_Allocators 7

There are no allocators for task types or types containing task subcomponents.

{*AI05-0224-1*} In the case of an initialized allocator of an access type whose designated type is class-wide and limited, a check is made that the specific type of the allocated object has no task subcomponents. Program_Error is raised if this check fails. 7.1/3

No_Implicit_Heap_Allocations 8

There are no operations that implicitly require heap storage allocation to be performed by the implementation. The operations that implicitly require heap storage allocation are implementation defined.

Implementation defined: Any operations that implicitly require heap storage allocation. 8.a

{*AI95-00327-01*} No_Dynamic_Priorities 9/2

There are no semantic dependences on the package Dynamic_Priorities, and no occurrences of the attribute Priority.

{*AI95-00305-01*} {*AI95-00394-01*} {*AI05-0013-1*} {*AI05-0211-1*} No_Dynamic_Attachment 10/3

There is no use of a name denoting any of the operations defined in package Interrupts (Is_Reserved, Is_Attached, Current_Handler, Attach_Handler, Exchange_Handler, Detach_Handler, and Reference).

Ramification: {*AI05-0013-1*} This includes 'Access and 'Address of any of these operations, as well as inherited versions of these operations. 10.a/3

{*AI12-0055-1*} No_Dynamic_CPU_Assignment 10.1/4

No task has the CPU aspect specified to be a non-static expression. Each task (including the environment task) that has the CPU aspect specified as Not_A_Specific_CPU will be assigned to a particular implementation-defined CPU. The same is true for the environment task when the CPU aspect is not specified. [Any other task without a CPU aspect will activate and execute on the same processor as its activating task.]

Proof: The processor of a task without a CPU aspect is defined in D.16, and this restriction guarantees that the activator always has a CPU assigned. 10.b/4

Reason: This restriction prevents any migration of tasks. 10.c/4

Ramification: If no CPU aspects are specified, then the program will run on a single CPU, as all of the tasks will be activated directly or indirectly by the environment task, and the rules require the same CPU to be used as the activating task. 10.d/4

Implementation defined: When restriction No_Dynamic_CPU_Assignment applies to a partition, the processor on which a task with a CPU value of a Not_A_Specific_CPU will execute. 10.d.1/4

{*AI95-00305-01*} {*AI05-0013-1*} No_Local_Protected_Objects 10.2/3

Protected objects are declared only at library level.

{*AI95-00297-01*} {*AI05-0013-1*} No_Local_Timing_Events 10.3/3

Timing_Events are declared only at library level.

{*AI95-00305-01*} No_Protected_Type_Allocators 10.4/2

There are no allocators for protected types or types containing protected type subcomponents.

{*AI05-0224-1*} In the case of an initialized allocator of an access type whose designated type is class-wide and limited, a check is made that the specific type of the allocated object has no protected subcomponents. Program_Error is raised if this check fails. 10.5/3

10.6/3 {*AI95-00305-01*} {*AI05-0211-1*} No_Relative_Delay
There are no delay_relative_statements, and there is no use of a name that denotes the Timing_Events.Set_Handler subprogram that has a Time_Span parameter.

10.7/3 {*AI95-00305-01*} No_Requeue_Statements
There are no requeue_statements.

10.8/3 {*AI95-00305-01*} No_Select_Statements
There are no select_statements.

10.9/3 {*AI95-00394-01*} {*AI05-0211-1*} No_Specific_Termination_Handlers
There is no use of a name denoting the Set_Specific_Handler and Specific_Handler subprograms in Task_Termination.

10.10/4 {*AI12-0117-1*} No_Tasks_Unassigned_To_CPU
The CPU aspect is specified for the environment task. No CPU aspect is specified to be statically equal to Not_A_Specific_CPU. If aspect CPU is specified (dynamically) to the value Not_A_Specific_CPU, then Program_Error is raised. If Set_CPU or Delay_Until_And_Set_CPU are called with the CPU parameter equal to Not_A_Specific_CPU, then Program_Error is raised.

10.e/4 **Ramification:** If this restriction is used in a context for which restriction No_Dynamic_CPU_Assignment is in effect, then no runtime check is needed when specifying the CPU aspect. If the restriction is used with the Ravenscar profile, no runtime checks are needed.

10.11/5 {*AI12-0290-1*} Pure_Barriers
The Boolean expression in each protected entry barrier is pure-barrier-eligible.

10.12/5 {*AI95-00305-01*} {*AI05-0013-1*} {*AI12-0369-1*} Simple_Barriers
The Boolean expression in each entry barrier is either a static expression or a name that statically names (see 4.9) a subcomponent of the enclosing protected object.

11 The following *restriction_parameter*_identifiers are language defined:

12 Max_Select_Alternatives
Specifies the maximum number of alternatives in a selective_accept.

13 Max_Task_Entries
Specifies the maximum number of entries per task. The bounds of every entry family of a task unit shall be static, or shall be defined by a discriminant of a subtype whose corresponding bound is static. [A value of zero indicates that no rendezvous are possible.]

14 Max_Protected_Entries
Specifies the maximum number of entries per protected type. The bounds of every entry family of a protected unit shall be static, or shall be defined by a discriminant of a subtype whose corresponding bound is static.

Dynamic Semantics

15/2 {*8652/0076*} {*AI95-00067-01*} {*AI95-00305-01*} The following *restriction*_identifier is language defined:

15.1/2 {*AI95-00305-01*} {*AI95-00394-01*} No_Task_Termination
All tasks are nonterminating. It is implementation-defined what happens if a task attempts to terminate. If there is a fall-back handler (see C.7.3) set for the partition it should be called when the first task attempts to terminate.

15.a.1/2 **Implementation defined:** When restriction No_Task_Termination applies to a partition, what happens when a task terminates.

16 The following *restriction_parameter*_identifiers are language defined:

{*8652/0076*} {*AI95-00067-01*} Max_Storage_At_Blocking 17/1

Specifies the maximum portion [(in storage elements)] of a task's Storage_Size that can be retained by a blocked task. If an implementation chooses to detect a violation of this restriction, Storage_Error should be raised; otherwise, the behavior is implementation defined.

Implementation defined: The behavior when restriction Max_Storage_At_Blocking is violated. 17.a.1/2

{*8652/0076*} {*AI95-00067-01*} Max_Asynchronous_Select_Nesting 18/1

Specifies the maximum dynamic nesting level of asynchronous_selects. A value of zero prevents the use of any asynchronous_select and, if a program contains an asynchronous_-select, it is illegal. If an implementation chooses to detect a violation of this restriction for values other than zero, Storage_Error should be raised; otherwise, the behavior is implementation defined.

Implementation defined: The behavior when restriction Max_Asynchronous_Select_Nesting is violated. 18.a.1/2

{*8652/0076*} {*AI95-00067-01*} Max_Tasks 19/1

Specifies the maximum number of task creations that may be executed over the lifetime of a partition, not counting the creation of the environment task. A value of zero prevents any task creation and, if a program contains a task creation, it is illegal. If an implementation chooses to detect a violation of this restriction, Storage_Error should be raised; otherwise, the behavior is implementation defined.

Ramification: Note that this is not a limit on the number of tasks active at a given time; it is a limit on the total number of task creations that occur. 19.a

Implementation Note: We envision an implementation approach that places TCBs or pointers to them in a fixed-size table, and never reuses table elements. 19.b

Implementation defined: The behavior when restriction Max_Tasks is violated. 19.b.1/2

{*AI95-00305-01*} Max_Entry_Queue_Length 19.1/2

Max_Entry_Queue_Length defines the maximum number of calls that are queued on an entry. Violation of this restriction results in the raising of Program_Error at the point of the call or requeue.

{*AI05-0189-1*} No_Standard_Allocators_After_Elaboration 19.2/3

Specifies that an allocator using a standard storage pool (see 13.11) shall not occur within a parameterless library subprogram, nor within the handled_sequence_of_statements of a task body. For the purposes of this rule, an allocator of a type derived from a formal access type does not use a standard storage pool.

{*AI05-0189-1*} {*AI05-0262-1*} At run time, Storage_Error is raised if an allocator using a standard storage pool is evaluated after the elaboration of the library_items of the partition has completed. 19.3/3

It is implementation defined whether the use of pragma Restrictions results in a reduction in executable program size, storage requirements, or execution time. If possible, the implementation should provide quantitative descriptions of such effects for each restriction. 20

Implementation defined: Whether the use of pragma Restrictions results in a reduction in program code or data size or execution time. 20.a/2

Implementation Advice

When feasible, the implementation should take advantage of the specified restrictions to produce a more efficient implementation. 21

Implementation Advice: When feasible, specified restrictions should be used to produce a more efficient implementation. 21.a/2

NOTE The above Storage_Checks can be suppressed with pragma Suppress. 22

Incompatibilities With Ada 95

22.a/2 {*AI95-00360-01*} **Amendment Correction:** The No_Nested_Finalization is now defined in terms of types that need finalization. These types include a variety of language-defined types that *might* be implemented with a controlled type. If the restriction No_Nested_Finalization (see D.7) applies to the partition, and one of these language-defined types does not have a controlled part, it will not be allowed in local objects in Ada 2005 whereas it would be allowed in original Ada 95. Such code is not portable, as other Ada compilers may have had a controlled part, and thus would be illegal under the restriction.

Extensions to Ada 95

22.b/2 {*AI95-00297-01*} {*AI95-00305-01*} {*AI95-00394-01*} Restrictions No_Dynamic_Attachment, No_Local_Protected_Objects, No_Protected_Type_Allocators, No_Local_Timing_Events, No_Relative_Delay, No_Requeue_Statement, No_Select_Statements, No_Specific_Termination_Handlers, No_Task_Termination, Max_Entry_Queue_Length, and Simple_Barriers are newly added to Ada.

Wording Changes from Ada 95

22.c/2 {*8652/0042*} {*AI95-00130-01*} **Corrigendum:** Clarified that No_Nested_Finalization covered task and protected parts as well.

22.d/2 {*8652/0076*} {*AI95-00067-01*} **Corrigendum:** Changed the description of Max_Tasks and Max_Asynchronous_Select_Nested to eliminate conflicts with the High Integrity Annex (see H.4).

22.e/2 {*AI95-00327-01*} Added using of the new Priority attribute to the restriction No_Dynamic_Priorities.

22.f/2 {*AI95-00394-01*} Restriction No_Asynchronous_Control is now obsolescent.

Incompatibilities With Ada 2005

22.g/3 {*AI05-0013-1*} **Correction:** Changed so that coextensions of types that require nested finalization are also prohibited; this is done by prohibiting allocators rather than objects of specific access types. It seems unlikely that any program depending on this restriction would violate it in this blatant manner, so it is expected that very few programs will be affected by this change.

22.h/3 {*AI05-0211-1*} **Correction:** The restriction No_Relative_Delay was changed to include the Timing_Events routine that uses a relative delay. This means that a program that uses that routine and this restriction will now be rejected. However, such a program violates the spirit and intent of the restriction and as such the program should never have been allowed. Moreover, it is unlikely that any program depending on this restriction would violate it in such an obvious manner, so it is expected that very few programs will be affected by this change.

22.i/3 {*AI05-0211-1*} **Correction:** A number of restrictions were changed from "no calls" on some subprogram to "no use of a name that denotes" that subprogram. This closes a hole where renames, uses as the prefix of 'Access, and the like, would not be rejected by the restriction, possibly allowing backdoor access to the prohibited subprogram. A program that uses one of these restrictions and using such backdoor access will now be rejected; however, it is extremely unlikely that any program that relies on these restrictions would also use an end-run around the restriction, so it is expected that very few programs will be affected by this change.

Extensions to Ada 2005

22.j/3 {*AI05-0189-1*} Restriction No_Standard_Allocators_After_Elaboration is newly added to Ada.

Wording Changes from Ada 2005

22.k/3 {*AI05-0013-1*} {*AI05-0216-1*} **Correction:** Improved the wording of various restrictions to make it clearer that they prohibit things that would otherwise be legal, and to word them as definitions, not Legality Rules;.

22.l/3 {*AI05-0192-1*} **Correction:** Added wording to explain how No_Task_Allocators and No_Protected_Type_Allocators are checked for class-wide types. This might be an extension if the compiler assumed the worst in the past (it is now a runtime check).

Extensions to Ada 2012

22.m/4 {*AI12-0055-1*} **Corrigendum:** Restriction No_Dynamic_CPU_Assignment is newly added to Ada, for use as part of the Ravenscar profile (see D.13).

22.n/4 {*AI12-0117-1*} **Corrigendum:** Restriction No_Tasks_Unassigned_To_CPU is newly added to Ada; it ensures that no task is running on an implementation-defined CPU so that task scheduling can be analyzed.

22.o/5 {*AI12-0290-1*} {*AI12-0369-1*} Restriction Pure_Barriers is newly added to Ada; it allows the Jorvik profile to use more expressive barriers than the Ravenscar profile without having to worry about exceptions or side-effects.

{*AI12-0369-1*} Restriction Simple_Barriers (which is part of the Ravenscar profile) is extended to allow statically named record and array subcomponents; this allows common static analysis patterns to be used with Ravenscar. 22.p/5

D.8 Monotonic Time

{*AI05-0299-1*} [This subclause specifies a high-resolution, monotonic clock package.] 1/3

Static Semantics

The following language-defined library package exists: 2

{*AI12-0241-1*} {*AI12-0302-1*} **package** Ada.Real_Time 3/5
  with Nonblocking, Global => **in out synchronized is**

   ... -- *not specified by the language*
end Ada.Real_Time;

This paragraph was deleted. 17.a/2

18 In this Annex, *real time* is defined to be the physical time as observed in the external environment. The type Time is a *time type* as defined by 9.6; [values of this type may be used in a delay_until_statement.] Values of this type represent segments of an ideal time line. The set of values of the type Time corresponds one-to-one with an implementation-defined range of mathematical integers.

18.a **Discussion:** Informally, real time is defined to be the International Atomic Time (TAI) which is monotonic and nondecreasing. We use it here for the purpose of discussing rate of change and monotonic behavior only. It does not imply anything about the absolute value of Real_Time.Clock, or about Real_Time.Time being synchronized with TAI. It is also used for real time in the metrics, for comparison purposes.

18.b **Implementation Note:** The specification of TAI as "real time" does not preclude the use of a simulated TAI clock for simulated execution environments.

19 The Time value I represents the half-open real time interval that starts with E+I*Time_Unit and is limited by E+(I+1)*Time_Unit, where Time_Unit is an implementation-defined real number and E is an unspecified origin point, the *epoch*, that is the same for all values of the type Time. It is not specified by the language whether the time values are synchronized with any standard time reference. [For example, E can correspond to the time of system initialization or it can correspond to the epoch of some time standard.]

19.a **Discussion:** E itself does not have to be a proper time value.

19.b This half-open interval I consists of all real numbers R such that E+I*Time_Unit <= R < E+(I+1)*Time_Unit.

20 Values of the type Time_Span represent length of real time duration. The set of values of this type corresponds one-to-one with an implementation-defined range of mathematical integers. The Time_Span value corresponding to the integer I represents the real-time duration I*Time_Unit.

20.a **Reason:** The purpose of this type is similar to Standard.Duration; the idea is to have a type with a higher resolution.

20.b **Discussion:** We looked at many possible names for this type: Real_Time.Duration, Fine_Duration, Interval, Time_Interval_Length, Time_Measure, and more. Each of these names had some problems, and we've finally settled for Time_Span.

21 Time_First and Time_Last are the smallest and largest values of the Time type, respectively. Similarly, Time_Span_First and Time_Span_Last are the smallest and largest values of the Time_Span type, respectively.

22 A value of type Seconds_Count represents an elapsed time, measured in seconds, since the epoch.

Dynamic Semantics

23 Time_Unit is the smallest amount of real time representable by the Time type; it is expressed in seconds. Time_Span_Unit is the difference between two successive values of the Time type. It is also the smallest positive value of type Time_Span. Time_Unit and Time_Span_Unit represent the same real time duration. A *clock tick* is a real time interval during which the clock value (as observed by calling the Clock function) remains constant. Tick is the average length of such intervals.

24/2 {*AI95-00432-01*} The function To_Duration converts the value TS to a value of type Duration. Similarly, the function To_Time_Span converts the value D to a value of type Time_Span. For To_Duration, the result is rounded to the nearest value of type Duration (away from zero if exactly halfway between two values). If the result is outside the range of Duration, Constraint_Error is raised. For To_Time_Span, the value of D is first rounded to the nearest integral multiple of Time_Unit, away from zero if exactly halfway between two multiples. If the rounded value is outside the range of Time_Span, Constraint_Error is raised. Otherwise, the value is converted to the type Time_Span.

25 To_Duration(Time_Span_Zero) returns 0.0, and To_Time_Span(0.0) returns Time_Span_Zero.

26/2 {*AI95-00386-01*} {*AI95-00432-01*} The functions Nanoseconds, Microseconds, Milliseconds, Seconds, and Minutes convert the input parameter to a value of the type Time_Span. NS, US, MS, S, and M are interpreted as a number of nanoseconds, microseconds, milliseconds, seconds, and minutes respectively.

The input parameter is first converted to seconds and rounded to the nearest integral multiple of Time_Unit, away from zero if exactly halfway between two multiples. If the rounded value is outside the range of Time_Span, Constraint_Error is raised. Otherwise, the rounded value is converted to the type Time_Span.

This paragraph was deleted.{*AI95-00432-01*} 26.a/2

The effects of the operators on Time and Time_Span are as for the operators defined for integer types. 27

Implementation Note: Though time values are modeled by integers, the types Time and Time_Span need not be implemented as integers. 27.a

The function Clock returns the amount of time since the epoch. 28

The effects of the Split and Time_Of operations are defined as follows, treating values of type Time, Time_Span, and Seconds_Count as mathematical integers. The effect of Split(T,SC,TS) is to set SC and TS to values such that T*Time_Unit = SC*1.0 + TS*Time_Unit, and 0.0 <= TS*Time_Unit < 1.0. The value returned by Time_Of(SC,TS) is the value T such that T*Time_Unit = SC*1.0 + TS*Time_Unit. 29

Implementation Requirements

The range of Time values shall be sufficient to uniquely represent the range of real times from program start-up to 50 years later. Tick shall be no greater than 1 millisecond. Time_Unit shall be less than or equal to 20 microseconds. 30

Implementation Note: The required range and accuracy of Time are such that 32-bits worth of seconds and 32-bits worth of ticks in a second could be used as the representation. 30.a

{*AI12-0451-1*} The value of Time_Span_First in seconds shall be no greater than –3600, and the value of Time_Span_Last in seconds shall be no less than 3600. 31/5

Reason: This is equivalent to ± one hour and there is still room for a two-microsecond resolution. 31.a

A *clock jump* is the difference between two successive distinct values of the clock (as observed by calling the Clock function). There shall be no backward clock jumps. 32

Documentation Requirements

The implementation shall document the values of Time_First, Time_Last, Time_Span_First, Time_Span_Last, Time_Span_Unit, and Tick. 33

Documentation Requirement: The values of Time_First, Time_Last, Time_Span_First, Time_Span_Last, Time_Span_Unit, and Tick for package Real_Time. 33.a/2

The implementation shall document the properties of the underlying time base used for the clock and for type Time, such as the range of values supported and any relevant aspects of the underlying hardware or operating system facilities used. 34

Documentation Requirement: The properties of the underlying time base used in package Real_Time. 34.a.1/2

Discussion: If there is an underlying operating system, this might include information about which system call is used to implement the clock. Otherwise, it might include information about which hardware clock is used. 34.a

The implementation shall document whether or not there is any synchronization with external time references, and if such synchronization exists, the sources of synchronization information, the frequency of synchronization, and the synchronization method applied. 35

Documentation Requirement: Any synchronization of package Real_Time with external time references. 35.a.1/2

{*AI05-0299-1*} {*AI12-0439-1*} The implementation shall document any aspects of the external environment that can interfere with the clock behavior as defined in this subclause. 36/5

Documentation Requirement: Any aspects of the external environment that can interfere with package Real_Time. 36.a.1/5

36.a **Discussion:** For example, the implementation is allowed to rely on the time services of an underlying operating system, and this operating system clock can implement time zones or allow the clock to be reset by an operator. This dependence has to be documented.

Metrics

37/3 {*AI05-0299-1*} For the purpose of the metrics defined in this subclause, real time is defined to be the International Atomic Time (TAI).

38 The implementation shall document the following metrics:

39 • An upper bound on the real-time duration of a clock tick. This is a value D such that if t1 and t2 are any real times such that t1 < t2 and $Clock_{t1} = Clock_{t2}$ then t2 – t1 <= D.

40 • An upper bound on the size of a clock jump.

41 • An upper bound on the *drift rate* of Clock with respect to real time. This is a real number D such that

42 $E*(1–D) <= (Clock_{t+E} – Clock_t) <= E*(1+D)$
provided that: $Clock_t + E*(1+D) <= Time\_Last$.

43 • where $Clock_t$ is the value of Clock at time t, and E is a real time duration not less than 24 hours. The value of E used for this metric shall be reported.

43.a **Reason:** This metric is intended to provide a measurement of the long term (cumulative) deviation; therefore, 24 hours is the lower bound on the measurement period. On some implementations, this is also the maximum period, since the language does not require that the range of the type Duration be more than 24 hours. On those implementations that support longer-range Duration, longer measurements should be performed.

44 • An upper bound on the execution time of a call to the Clock function, in processor clock cycles.

45 • Upper bounds on the execution times of the operators of the types Time and Time_Span, in processor clock cycles.

45.a **Implementation Note:** A fast implementation of the Clock function involves repeated reading until you get the same value twice. It is highly improbable that more than three reads will be necessary. Arithmetic on time values should not be significantly slower than 64-bit arithmetic in the underlying machine instruction set.

45.a.1/2 **Documentation Requirement:** The metrics for package Real_Time.

Implementation Permissions

46/5 {*AI12-0444-1*} Implementations targeted to machines with word size smaller than 32 bits may omit support for the full range and granularity of the Time and Time_Span types.

46.a **Discussion:** These requirements are based on machines with a word size of 32 bits.

46.b Since the range and granularity are implementation defined, the supported values need to be documented.

Implementation Advice

47 When appropriate, implementations should provide configuration mechanisms to change the value of Tick.

47.a.1/2 **Implementation Advice:** When appropriate, mechanisms to change the value of Tick should be provided.

47.a **Reason:** This is often needed when the compilation system was originally targeted to a particular processor with a particular interval timer, but the customer uses the same processor with a different interval timer.

47.b **Discussion:** Tick is a deferred constant and not a named number specifically for this purpose.

47.c **Implementation Note:** This can be achieved either by pre-run-time configuration tools, or by having Tick be initialized (in the package private part) by a function call residing in a board specific module.

48 It is recommended that Calendar.Clock and Real_Time.Clock be implemented as transformations of the same time base.

48.a.1/2 **Implementation Advice:** Calendar.Clock and Real_Time.Clock should be transformations of the same time base.

It is recommended that the “best” time base which exists in the underlying system be available to the application through Clock. “Best” may mean highest accuracy or largest range. 49

Implementation Advice: The “best” time base which exists in the underlying system should be available to the application through Real_Time.Clock. 49.a.1/2

NOTE 1 {*AI05-0299-1*} The rules in this subclause do not imply that the implementation can protect the user from operator or installation errors that can result in the clock being set incorrectly. 50/3

NOTE 2 Time_Unit is the granularity of the Time type. In contrast, Tick represents the granularity of Real_Time.Clock. There is no requirement that these be the same. 51

Incompatibilities With Ada 95

{*AI95-00386-01*} {*AI05-0005-1*} Functions Seconds and Minutes are added to Real_Time. If Real_Time is referenced in a use_clause, and an entity *E* with a defining_identifier of Seconds or Minutes is defined in a package that is also referenced in a use_clause, the entity *E* may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur. 51.a/3

Wording Changes from Ada 95

{*AI95-00432-01*} Added wording explaining how and when many of these functions can raise Constraint_Error. While there always was an intent to raise Constraint_Error if the values did not fit, there never was any wording to that effect, and since Time_Span was a private type, the normal numeric type rules do not apply to it. 51.b/2

D.9 Delay Accuracy

{*AI05-0299-1*} [This subclause specifies performance requirements for the delay_statement. The rules apply both to delay_relative_statement and to delay_until_statement. Similarly, they apply equally to a simple delay_statement and to one which appears in a delay_alternative.] 1/3

Dynamic Semantics

The effect of the delay_statement for Real_Time.Time is defined in terms of Real_Time.Clock: 2

- If C_1 is a value of Clock read before a task executes a delay_relative_statement with duration D, and C_2 is a value of Clock read after the task resumes execution following that delay_statement, then $C_2 - C_1 >= D$. 3
- If C is a value of Clock read after a task resumes execution following a delay_until_statement with Real_Time.Time value T, then C >= T. 4

A simple delay_statement with a negative or zero value for the expiration time does not cause the calling task to be blocked; it is nevertheless a potentially blocking operation (see 9.5.1). 5

{*AI05-0004-1*} When a delay_statement appears in a delay_alternative of a timed_entry_call the selection of the entry call is attempted, regardless of the specified expiration time. When a delay_statement appears in a select_alternative, and a call is queued on one of the open entries, the selection of that entry call proceeds, regardless of the value of the delay expression. 6/3

Ramification: The effect of these requirements is that one has to always attempt a rendezvous, regardless of the value of the delay expression. This can be tested by issuing a timed_entry_call with an expiration time of zero, to an open entry. 6.a

Documentation Requirements

The implementation shall document the minimum value of the delay expression of a delay_relative_statement that causes the task to actually be blocked. 7

Documentation Requirement: The minimum value of the delay expression of a delay_relative_statement that causes a task to actually be blocked. 7.a/2

The implementation shall document the minimum difference between the value of the delay expression of a delay_until_statement and the value of Real_Time.Clock, that causes the task to actually be blocked. 8

8.a/2 *This paragraph was deleted.*

8.b/2 **Documentation Requirement:** The minimum difference between the value of the delay expression of a delay_until_statement and the value of Real_Time.Clock, that causes the task to actually be blocked.

Metrics

9 The implementation shall document the following metrics:

10 • An upper bound on the execution time, in processor clock cycles, of a delay_relative_statement whose requested value of the delay expression is less than or equal to zero.

11 • An upper bound on the execution time, in processor clock cycles, of a delay_until_statement whose requested value of the delay expression is less than or equal to the value of Real_Time.Clock at the time of executing the statement. Similarly, for Calendar.Clock.

12/5 • {*AI12-0445-1*} An upper bound on the *lateness* of a delay_relative_statement, for a positive value of the delay expression, in a situation where the task has sufficient priority to preempt the processor as soon as it becomes ready, and can proceed without waiting for any other execution resources. The upper bound is expressed as a function of the value of the delay expression. The lateness is obtained by subtracting the value of the delay expression from the *actual duration*. The actual duration is measured from a point immediately before a task executes the delay_statement to a point immediately after the task resumes execution following this statement.

13/5 • {*AI12-0445-1*} An upper bound on the lateness of a delay_until_statement, in a situation where the value of the requested expiration time is after the time the task begins executing the statement, the task has sufficient priority to preempt the processor as soon as it becomes ready, and it can proceed without waiting for any other execution resources. The upper bound is expressed as a function of the difference between the requested expiration time and the clock value at the time the statement begins execution. The lateness of a delay_until_statement is obtained by subtracting the requested expiration time from the real time that the task resumes execution following this statement.

13.a/2 **Documentation Requirement:** The metrics for delay statements.

Wording Changes from Ada 83

14.a The rules regarding a timed_entry_call with a very small positive Duration value, have been tightened to always require the check whether the rendezvous is immediately possible.

Wording Changes from Ada 95

14.b/2 {*AI95-00355-01*} The note about “voluntary round-robin’, while still true, has been deleted as potentially confusing as it is describing a different kind of round-robin than is defined by the round-robin dispatching policy.

D.10 Synchronous Task Control

1/3 {*AI05-0299-1*} [This subclause describes a language-defined private semaphore (suspension object), which can be used for *two-stage suspend* operations and as a simple building block for implementing higher-level queues.]

Static Semantics

2 The following language-defined package exists:

3/5
```
{AI95-00362-01} {AI12-0241-1} {AI12-0302-1} package Ada.Synchronous_Task_Control
  with Preelaborate, Nonblocking, Global => in out synchronized is
```

```
{AI12-0241-1}   type Suspension_Object is limited private;                                4/5
  procedure Set_True(S : in out Suspension_Object);
  procedure Set_False(S : in out Suspension_Object);
  function Current_State(S : Suspension_Object) return Boolean;
  procedure Suspend_Until_True(S : in out Suspension_Object)
     with Nonblocking => False;
private
     ... -- not specified by the language
end Ada.Synchronous_Task_Control;
```

The type Suspension_Object is a by-reference type. 5

Implementation Note: {*AI95-00318-02*} The implementation can ensure this by, for example, making the full view an explicitly limited record type. 5.a/2

{*AI05-0168-1*} The following language-defined package exists: 5.1/3

```
{AI05-0168-1} {AI12-0241-1} {AI12-0302-1} with Ada.Real_Time;                            5.2/5
package Ada.Synchronous_Task_Control.EDF
   with Nonblocking, Global => in out synchronized is
   procedure Suspend_Until_True_And_Set_Deadline
      (S  : in out Suspension_Object;
       TS : in     Ada.Real_Time.Time_Span)
      with Nonblocking => False;
end Ada.Synchronous_Task_Control.EDF;
```

Dynamic Semantics

{*AI95-00114-01*} An object of the type Suspension_Object has two visible states: True and False. Upon initialization, its value is set to False. 6/2

Discussion: This object is assumed to be private to the declaring task, i.e. only that task will call Suspend_Until_True on this object, and the count of callers is at most one. Other tasks can, of course, change and query the state of this object. 6.a

{*AI95-00114-01*} The operations Set_True and Set_False are atomic with respect to each other and with respect to Suspend_Until_True; they set the state to True and False respectively. 7/2

Current_State returns the current state of the object. 8

Discussion: This state can change immediately after the operation returns. 8.a

{*AI95-00114-01*} The procedure Suspend_Until_True blocks the calling task until the state of the object S is True; at that point the task becomes ready and the state of the object becomes False. 9/2

{*AI12-0241-1*} Program_Error is raised upon calling Suspend_Until_True if another task is already waiting on that suspension object. 10/5

{*AI05-0168-1*} {*AI05-0269-1*} {*AI12-0241-1*} The procedure Suspend_Until_True_And_Set_Deadline blocks the calling task until the state of the object S is True; at that point the task becomes ready with a deadline of Ada.Real_Time.Clock + TS, and the state of the object becomes False. Program_Error is raised upon calling Suspend_Until_True_And_Set_Deadline if another task is already waiting on that suspension object. 10.1/5

Bounded (Run-Time) Errors

{*AI12-0171-1*} {*AI12-0439-1*} It is a bounded error for two or more tasks to call Suspend_Until_True on the same Suspension_Object concurrently. For each task, Program_Error can be raised, the task can proceed without suspending, or the task can suspend, potentially indefinitely. The state of the suspension object can end up either True or False. 10.2/5

Implementation Requirements

The implementation is required to allow the calling of Set_False and Set_True during any protected action, even one that has its ceiling priority in the Interrupt_Priority range. 11

12/3 NOTE {*AI05-0168-1*} More complex schemes, such as setting the deadline relative to when Set_True is called, can be programmed using a protected object.

Extensions to Ada 95

12.a/2 {*AI95-00362-01*} Synchronous_Task_Control is now Preelaborated, so it can be used in preelaborated units.

Extensions to Ada 2005

12.b/3 {*AI05-0168-1*} Child package Ada.Synchronous_Task_Control.EDF is new.

Wording Changes from Ada 2012

12.c/5 {*AI12-0171-1*} **Correction:** Clarified that Suspend_Until_True should only be called from a single task, and what happens if that is violated.

D.10.1 Synchronous Barriers

1/3 {*AI05-0174-1*} {*AI05-0299-1*} This subclause introduces a language-defined package to synchronously release a group of tasks after the number of blocked tasks reaches a specified count value.

Static Semantics

2/3 {*AI05-0174-1*} The following language-defined library package exists:

3/5
```
{AI12-0241-1} {AI12-0302-1} package Ada.Synchronous_Barriers
   with Preelaborate, Nonblocking, Global => in out synchronized is
```

4/3
```
   subtype Barrier_Limit is Positive range 1 .. implementation-defined;
```

4.a.1/3 **Implementation defined:** The value of Barrier_Limit'Last in Synchronous_Barriers.

5/3
```
   type Synchronous_Barrier (Release_Threshold : Barrier_Limit) is limited private;
```

6/5
```
{AI12-0241-1}    procedure Wait_For_Release (The_Barrier : in out
Synchronous_Barrier;
                                Notified    :    out Boolean)
      with Nonblocking => False;
```

7/3
```
private
   -- not specified by the language
end Ada.Synchronous_Barriers;
```

8/3 {*AI05-0174-1*} Type Synchronous_Barrier needs finalization (see 7.6).

Dynamic Semantics

9/3 {*AI05-0174-1*} Each call to Wait_For_Release blocks the calling task until the number of blocked tasks associated with the Synchronous_Barrier object is equal to Release_Threshold, at which time all blocked tasks are released. Notified is set to True for one of the released tasks, and set to False for all other released tasks.

10/3 {*AI05-0174-1*} The mechanism for determining which task sets Notified to True is implementation defined.

11/3 {*AI05-0174-1*} Once all tasks have been released, a Synchronous_Barrier object may be reused to block another Release_Threshold number of tasks.

12/3 {*AI05-0174-1*} As the first step of the finalization of a Synchronous_Barrier, each blocked task is unblocked and Program_Error is raised at the place of the call to Wait_For_Release.

13/3 {*AI05-0174-1*} It is implementation defined whether an abnormal task which is waiting on a Synchronous_Barrier object is aborted immediately or aborted when the tasks waiting on the object are released.

13.a.1/3 **Implementation defined:** When an aborted task that is waiting on a Synchronous_Barrier is aborted.

This paragraph was deleted.{*AI05-0174-1*} {*AI12-0241-1*} 14/5

Bounded (Run-Time) Errors

{*AI05-0174-1*} It is a bounded error to call Wait_For_Release on a Synchronous_Barrier object after that object is finalized. If the error is detected, Program_Error is raised. Otherwise, the call proceeds normally, which may leave a task blocked forever. 15/3

Extensions to Ada 2005

{*AI05-0174-1*} The package Ada.Synchronous_Barriers is new. 15.a/3

D.11 Asynchronous Task Control

{*AI05-0299-1*} [This subclause introduces a language-defined package to do asynchronous suspend/resume on tasks. It uses a conceptual *held priority* value to represent the task's *held* state.] 1/3

Static Semantics

The following language-defined library package exists: 2

{*AI95-00362-01*} {*AI12-0241-1*} {*AI12-0302-1*} 3/5

```
with Ada.Task_Identification;
package Ada.Asynchronous_Task_Control
  with Preelaborate, Nonblocking, Global => in out synchronized is
  procedure Hold(T : in Ada.Task_Identification.Task_Id);
  procedure Continue(T : in Ada.Task_Identification.Task_Id);
  function Is_Held(T : Ada.Task_Identification.Task_Id)
   return Boolean;
end Ada.Asynchronous_Task_Control;
```

Dynamic Semantics

{*AI95-00357-01*} After the Hold operation has been applied to a task, the task becomes *held*. For each processor there is a conceptual *idle task*, which is always ready. The base priority of the idle task is below System.Any_Priority'First. The *held priority* is a constant of the type Integer whose value is below the base priority of the idle task. 4/2

Discussion: The held state should not be confused with the blocked state as defined in 9.2; the task is still ready. 4.a

{*AI95-00357-01*} For any priority below System.Any_Priority'First, the task dispatching policy is FIFO_Within_Priorities. 4.1/2

To be honest: This applies even if a Task_Dispatching_Policy specifies the policy for all of the priorities of the partition. 4.b/2

Ramification: A task at the held priority never runs, so it is not necessary to implement FIFO_Within_Priorities for systems that have only one policy (such as EDF_Across_Priorities). 4.c/2

{*AI95-00357-01*} The Hold operation sets the state of T to held. For a held task, the active priority is reevaluated as if the base priority of the task were the held priority. 5/2

Ramification: For example, if T is currently inheriting priorities from other sources (e.g. it is executing in a protected action), its active priority does not change, and it continues to execute until it leaves the protected action. 5.a

{*AI95-00357-01*} The Continue operation resets the state of T to not-held; its active priority is then reevaluated as determined by the task dispatching policy associated with its base priority. 6/2

The Is_Held function returns True if and only if T is in the held state. 7

Discussion: Note that the state of T can be changed immediately after Is_Held returns. 7.a

As part of these operations, a check is made that the task identified by T is not terminated. Tasking_Error is raised if the check fails. Program_Error is raised if the value of T is Null_Task_Id. 8

Erroneous Execution

9 If any operation in this package is called with a parameter T that specifies a task object that no longer exists, the execution of the program is erroneous.

Implementation Permissions

10/5 {*AI12-0444-1*} An implementation may omit support for Asynchronous_Task_Control if it is infeasible to support it in the target environment.

10.a **Reason:** A direct implementation of the Asynchronous_Task_Control semantics using priorities is not necessarily efficient enough. Thus, we envision implementations that use some other mechanism to set the "held" state. If there is no other such mechanism, support for Asynchronous_Task_Control might be infeasible, because an implementation in terms of priority would require one idle task per processor. On some systems, programs are not supposed to know how many processors are available, so creating enough idle tasks would be problematic.

11 NOTE 1 It is a consequence of the priority rules that held tasks cannot be dispatched on any processor in a partition (unless they are inheriting priorities) since their priorities are defined to be below the priority of any idle task.

12 NOTE 2 The effect of calling Get_Priority and Set_Priority on a Held task is the same as on any other task.

13 NOTE 3 Calling Hold on a held task or Continue on a non-held task has no effect.

14 NOTE 4 The rules affecting queuing are derived from the above rules, in addition to the normal priority rules:

15 • When a held task is on the ready queue, its priority is so low as to never reach the top of the queue as long as there are other tasks on that queue.

16 • If a task is executing in a protected action, inside a rendezvous, or is inheriting priorities from other sources (e.g. when activated), it continues to execute until it is no longer executing the corresponding construct.

17 • If a task becomes held while waiting (as a caller) for a rendezvous to complete, the active priority of the accepting task is not affected.

18/1 • {*8652/0077*} {*AI95-00111-01*} If a task becomes held while waiting in a selective_accept, and an entry call is issued to one of the open entries, the corresponding accept_alternative executes. When the rendezvous completes, the active priority of the accepting task is lowered to the held priority (unless it is still inheriting from other sources), and the task does not execute until another Continue.

19 • The same holds if the held task is the only task on a protected entry queue whose barrier becomes open. The corresponding entry body executes.

Extensions to Ada 95

19.a/2 {*AI95-00362-01*} Asynchronous_Task_Control is now Preelaborated, so it can be used in preelaborated units.

Wording Changes from Ada 95

19.b/2 {*8652/0077*} {*AI95-00111-01*} **Corrigendum:** Corrected to eliminate the use of the undefined term "accept body".

19.c/2 {*AI95-00357-01*} The description of held tasks was changed to reflect that the calculation of active priorities depends on the dispatching policy of the base priority. Thus, the policy of the held priority was specified in order to avoid surprises (especially when using the EDF policy).

D.12 Other Optimizations and Determinism Rules

1/3 {*AI05-0299-1*} [This subclause describes various requirements for improving the response and determinism in a real-time system.]

Implementation Requirements

2 If the implementation blocks interrupts (see C.3) not as a result of direct user action (e.g. an execution of a protected action) there shall be an upper bound on the duration of this blocking.

2.a **Ramification:** The implementation shall not allow itself to be interrupted when it is in a state where it is unable to support all the language-defined operations permitted in the execution of interrupt handlers. (see 9.5.1).

The implementation shall recognize entry-less protected types. The overhead of acquiring the execution resource of an object of such a type (see 9.5.1) shall be minimized. In particular, there should not be any overhead due to evaluating entry_barrier conditions. 3

Implementation Note: Ideally the overhead should just be a spin-lock. 3.a

Unchecked_Deallocation shall be supported for terminated tasks that are designated by access types, and shall have the effect of releasing all the storage associated with the task. This includes any run-time system or heap storage that has been implicitly allocated for the task by the implementation. 4

Documentation Requirements

The implementation shall document the upper bound on the duration of interrupt blocking caused by the implementation. If this is different for different interrupts or interrupt priority levels, it should be documented for each case. 5

This paragraph was deleted. 5.a/2

Documentation Requirement: The upper bound on the duration of interrupt blocking caused by the implementation. 5.b/2

Metrics

The implementation shall document the following metric: 6

- The overhead associated with obtaining a mutual-exclusive access to an entry-less protected object. This shall be measured in the following way: 7

  For a protected object of the form: 8

```
protected Lock is                                                    9
   procedure Set;
   function Read return Boolean;
private
   Flag : Boolean := False;
end Lock;

protected body Lock is                                               10
   procedure Set is
   begin
      Flag := True;
   end Set;
   function Read return Boolean
   begin
      return Flag;
   end Read;
end Lock;
```

  The execution time, in processor clock cycles, of a call to Set. This shall be measured between the point just before issuing the call, and the point just after the call completes. The function Read shall be called later to verify that Set was indeed called (and not optimized away). The calling task shall have sufficiently high priority as to not be preempted during the measurement period. The protected object shall have sufficiently high ceiling priority to allow the task to call Set. 11

  For a multiprocessor, if supported, the metric shall be reported for the case where no contention (on the execution resource) exists [from tasks executing on other processors]. 12

  Documentation Requirement: The metrics for entry-less protected objects. 12.a/2

D.13 The Ravenscar and Jorvik Profiles

{*AI95-00249-01*} {*AI05-0246-1*} {*AI05-0299-1*} {*AI12-0291-1*} [This subclause defines the Ravenscar and Jorvik profiles.] 1/5

Paragraphs 2 and 3 were moved to 13.12, "Pragma Restrictions and Pragma Profile".

Legality Rules

4/3 {*AI95-00249-01*} {*AI05-0246-1*} {*AI12-0291-1*} The *profile*_identifier Ravenscar and *profile*_identifier Jorvik are usage profiles (see 13.12). For usage profiles Ravenscar and Jorvik, there shall be no *profile*_pragma_argument_associations.

Static Semantics

5/3 {*AI95-00249-01*} {*AI05-0246-1*} The usage profile Ravenscar is equivalent to the following set of pragmas:

6/4
```
{AI95-00249-01} {AI95-00297-01} {AI95-00394-01} {AI05-0171-1} {AI05-0246-1} {AI12-
0055-1} {AI12-0073-1} pragma Task_Dispatching_Policy (FIFO_Within_Priorities);
pragma Locking_Policy (Ceiling_Locking);
pragma Detect_Blocking;
pragma Restrictions (
             No_Abort_Statements,
             No_Dynamic_Attachment,
             No_Dynamic_CPU_Assignment,
             No_Dynamic_Priorities,
             No_Implicit_Heap_Allocations,
             No_Local_Protected_Objects,
             No_Local_Timing_Events,
             No_Protected_Type_Allocators,
             No_Relative_Delay,
             No_Requeue_Statements,
             No_Select_Statements,
             No_Specific_Termination_Handlers,
             No_Task_Allocators,
             No_Task_Hierarchy,
             No_Task_Termination,
             Simple_Barriers,
             Max_Entry_Queue_Length => 1,
             Max_Protected_Entries => 1,
             Max_Task_Entries => 0,
             No_Dependence => Ada.Asynchronous_Task_Control,
             No_Dependence => Ada.Calendar,
             No_Dependence => Ada.Execution_Time.Group_Budgets,
             No_Dependence => Ada.Execution_Time.Timers,
             No_Dependence => Ada.Synchronous_Barriers,
             No_Dependence => Ada.Task_Attributes,
             No_Dependence => System.Multiprocessors.Dispatching_Domains);
```

6.a/3 **Discussion:** The Ravenscar profile is named for the location of the meeting that defined its initial version. The name is now in widespread use, so we stick with existing practice, rather than using a more descriptive name.

6.b/5 The Jorvik profile is named for the city of York, UK, near where the Ravenscar profile was created. "Jorvik" (pronounced "Yorvick") was the Viking name for York.

6.1/5 {*AI12-0291-1*} The usage profile Jorvik is equivalent to the following set of pragmas:

```
{AI12-0291-1} pragma Task_Dispatching_Policy (FIFO_Within_Priorities);
pragma Locking_Policy (Ceiling_Locking);
pragma Detect_Blocking;
pragma Restrictions (
             No_Abort_Statements,
             No_Dynamic_Attachment,
             No_Dynamic_CPU_Assignment,
             No_Dynamic_Priorities,
             No_Local_Protected_Objects,
             No_Local_Timing_Events,
             No_Protected_Type_Allocators,
             No_Requeue_Statements,
             No_Select_Statements,
             No_Specific_Termination_Handlers,
             No_Task_Allocators,
             No_Task_Hierarchy,
             No_Task_Termination,
             Pure_Barriers,
             Max_Task_Entries => 0,
             No_Dependence => Ada.Asynchronous_Task_Control,
             No_Dependence => Ada.Execution_Time.Group_Budgets,
             No_Dependence => Ada.Execution_Time.Timers,
             No_Dependence => Ada.Task_Attributes,
             No_Dependence => System.Multiprocessors.Dispatching_Domains);
```

6.2/5

Discussion: The Jorvik profile removes a number of restrictions from the Ravenscar profile to allow additional applications to benefit from predictability and low overhead. Specifically, the following restrictions are removed: 6.c/5

No_Implicit_Heap_Allocations 6.d/5
No_Relative_Delay
Max_Entry_Queue_Length => 1
Max_Protected_Entries => 1
No_Dependence => Ada.Calendar
No_Dependence => Ada.Synchronous_Barriers

Jorvik also replaces restriction Simple_Barriers with Pure_Barriers (a weaker requirement than Simple_Barriers). 6.e/5

Paragraph 7 and 8 were deleted.

Implementation Advice

{*AI05-0171-1*} {*AI12-0291-1*} On a multiprocessor system, an implementation should support a fully partitioned approach if one of these profiles is specified. Each processor should have separate and disjoint ready queues. 9/5

Implementation Advice: On a multiprocessor system, each processor should have a separate and disjoint ready queue. 9.a.1/3

NOTE 1 {*AI95-00249-01*} {*AI05-0246-1*} {*AI12-0291-1*} For the Ravenscar profile, the effect of the restriction Max_Entry_Queue_Length => 1 applies only to protected entry queues due to the accompanying restriction Max_Task_Entries => 0. The restriction Max_Entry_Queue_Length is not applied by the Jorvik profile. 10/5

NOTE 2 {*AI12-0055-1*} {*AI12-0291-1*} When the Ravenscar or Jorvik profile is in effect (via the effect of the No_Dynamic_CPU_Assignment restriction), all of the tasks in the partition will execute on a single CPU unless the programmer explicitly uses aspect CPU to specify the CPU assignments for tasks. The use of multiple CPUs requires care, as many guarantees of single CPU scheduling no longer apply. 11/5

NOTE 3 {*AI12-0055-1*} {*AI12-0291-1*} It is not recommended to specify the CPU of a task to be Not_A_Specific_CPU when the Ravenscar or Jorvik profile is in effect. How a partition executes strongly depends on the assignment of tasks to CPUs. 12/5

NOTE 4 {*AI12-0291-1*} Any unit that meets the requirements of the Ravenscar profile also meets the requirements of the Jorvik profile. 13/5

Extensions to Ada 95

{*AI95-00249-01*} {*AI05-0246-1*} The Ravenscar profile is new; it was moved here by Ada 2012. 13.a/3

Wording Changes from Ada 2005

{*AI05-0171-1*} How Ravenscar behaves on a multiprocessor system is now defined. 13.b/3

Incompatibilities With Ada 2012

13.c/4 {*AI05-0073-1*} **Corrigendum:** The Ravenscar profile no longer allows the use of package Synchronous_Barriers, as this package violates the fundamental Ravenscar requirement that each waiting point can only block (and release) a single task. This is incompatible with the published Ada 2012 standard, but it is unlikely that any existing Ravenscar runtime ever usefully supported barriers.

13.d/4 {*AI05-0055-1*} **Corrigendum:**The Ravenscar profile (via the effect of the new restriction No_Dynamic_CPU_Assignment) no longer allows setting the CPU aspect of a task to a non-static value. While this was allowed, an implementation would have had to come up with a creative interpretation of the Ada 2012 requirement to define the association of tasks to processors statically. As such, the new check is more likely to catch bugs than break a working program.

Extensions to Ada 2012

13.e/5 {*AI12-0291-1*} The Jorvik profile is new.

D.14 Execution Time

1/3 {*AI95-00307-01*} {*AI05-0299-1*} This subclause describes a language-defined package to measure execution time.

Static Semantics

2/2 {*AI95-00307-01*} The following language-defined library package exists:

3/5
```
{AI12-0241-1} {AI12-0302-1} with Ada.Task_Identification;
with Ada.Real_Time; use Ada.Real_Time;
package Ada.Execution_Time
   with Nonblocking, Global => in out synchronized is
```

4/2
```
   type CPU_Time is private;
   CPU_Time_First : constant CPU_Time;
   CPU_Time_Last  : constant CPU_Time;
   CPU_Time_Unit  : constant := implementation-defined-real-number;
   CPU_Tick : constant Time_Span;
```

5/2
```
   function Clock
     (T : Ada.Task_Identification.Task_Id
          := Ada.Task_Identification.Current_Task)
     return CPU_Time;
```

6/2
```
   function "+"  (Left : CPU_Time; Right : Time_Span) return CPU_Time;
   function "+"  (Left : Time_Span; Right : CPU_Time) return CPU_Time;
   function "-"  (Left : CPU_Time; Right : Time_Span) return CPU_Time;
   function "-"  (Left : CPU_Time; Right : CPU_Time)  return Time_Span;
```

7/2
```
   function "<"  (Left, Right : CPU_Time) return Boolean;
   function "<=" (Left, Right : CPU_Time) return Boolean;
   function ">"  (Left, Right : CPU_Time) return Boolean;
   function ">=" (Left, Right : CPU_Time) return Boolean;
```

8/2
```
   procedure Split
     (T : in CPU_Time; SC : out Seconds_Count; TS : out Time_Span);
```

9/2
```
   function Time_Of (SC : Seconds_Count;
                     TS : Time_Span := Time_Span_Zero) return CPU_Time;
```

9.1/3
```
   {AI05-0170-1}    Interrupt_Clocks_Supported : constant Boolean := implementation-defined;
```

9.2/3
```
   {AI05-0170-1}    Separate_Interrupt_Clocks_Supported : constant Boolean :=
        implementation-defined;
```

9.3/3
```
   {AI05-0170-1}    function Clock_For_Interrupts return CPU_Time;
```

10/2
```
   private
      ... -- not specified by the language
   end Ada.Execution_Time;
```

11/3 {*AI95-00307-01*} {*AI05-0170-1*} {*AI05-0269-1*} The *execution time* or CPU time of a given task is defined as the time spent by the system executing that task, including the time spent executing run-time or

system services on its behalf. The mechanism used to measure execution time is implementation defined. The Boolean constant Interrupt_Clocks_Supported is set to True if the implementation separately accounts for the execution time of interrupt handlers. If it is set to False it is implementation defined which task, if any, is charged the execution time that is consumed by interrupt handlers. The Boolean constant Separate_Interrupt_Clocks_Supported is set to True if the implementation separately accounts for the execution time of individual interrupt handlers (see D.14.3).

Discussion: The implementation-defined properties above and of the values declared in the package are repeated in Documentation Requirements, so we don't mark them as implementation-defined. 11.a/2

{*AI95-00307-01*} The type CPU_Time represents the execution time of a task. The set of values of this type corresponds one-to-one with an implementation-defined range of mathematical integers. 12/2

{*AI95-00307-01*} The CPU_Time value I represents the half-open execution-time interval that starts with I*CPU_Time_Unit and is limited by (I+1)*CPU_Time_Unit, where CPU_Time_Unit is an implementation-defined real number. For each task, the execution time value is set to zero at the creation of the task. 13/2

Ramification: Since it is implementation-defined which task is charged execution time for system services, the execution time value may become nonzero even before the start of the activation of the task. 13.a/2

{*AI95-00307-01*} CPU_Time_First and CPU_Time_Last are the smallest and largest values of the CPU_Time type, respectively. 14/2

{*AI05-0170-1*} The execution time value for the function Clock_For_Interrupts is initialized to zero. 14.1/3

Dynamic Semantics

{*AI95-00307-01*} CPU_Time_Unit is the smallest amount of execution time representable by the CPU_Time type; it is expressed in seconds. A *CPU clock tick* is an execution time interval during which the clock value (as observed by calling the Clock function) remains constant. CPU_Tick is the average length of such intervals. 15/2

{*AI95-00307-01*} The effects of the operators on CPU_Time and Time_Span are as for the operators defined for integer types. 16/2

{*AI95-00307-01*} The function Clock returns the current execution time of the task identified by T; Tasking_Error is raised if that task has terminated; Program_Error is raised if the value of T is Task_Identification.Null_Task_Id. 17/2

{*AI95-00307-01*} The effects of the Split and Time_Of operations are defined as follows, treating values of type CPU_Time, Time_Span, and Seconds_Count as mathematical integers. The effect of Split (T, SC, TS) is to set SC and TS to values such that T*CPU_Time_Unit = SC*1.0 + TS*CPU_Time_Unit, and 0.0 <= TS*CPU_Time_Unit < 1.0. The value returned by Time_Of(SC,TS) is the execution-time value T such that T*CPU_Time_Unit=SC*1.0 + TS*CPU_Time_Unit. 18/2

{*AI05-0170-1*} The function Clock_For_Interrupts returns the total cumulative time spent executing within all interrupt handlers. This time is not allocated to any task execution time clock. If Interrupt_Clocks_Supported is set to False the function raises Program_Error. 18.1/3

Erroneous Execution

{*AI95-00307-01*} For a call of Clock, if the task identified by T no longer exists, the execution of the program is erroneous. 19/2

Implementation Requirements

20/2 {*AI95-00307-01*} The range of CPU_Time values shall be sufficient to uniquely represent the range of execution times from the task start-up to 50 years of execution time later. CPU_Tick shall be no greater than 1 millisecond.

Documentation Requirements

21/2 {*AI95-00307-01*} The implementation shall document the values of CPU_Time_First, CPU_Time_Last, CPU_Time_Unit, and CPU_Tick.

21.a/2 **Documentation Requirement:** The values of CPU_Time_First, CPU_Time_Last, CPU_Time_Unit, and CPU_Tick of package Execution_Time.

22/2 {*AI95-00307-01*} The implementation shall document the properties of the underlying mechanism used to measure execution times, such as the range of values supported and any relevant aspects of the underlying hardware or operating system facilities used.

22.a/3 **Documentation Requirement:** The properties of the mechanism used to implement package Execution_Time, including the values of the constants defined in the package.

Metrics

23/2 {*AI95-00307-01*} The implementation shall document the following metrics:

24/2 • An upper bound on the execution-time duration of a clock tick. This is a value D such that if t1 and t2 are any execution times of a given task such that t1 < t2 and $Clock_{t1}$ = $Clock_{t2}$ then t2 – t1 <= D.

25/2 • An upper bound on the size of a clock jump. A clock jump is the difference between two successive distinct values of an execution-time clock (as observed by calling the Clock function with the same Task_Id).

26/2 • An upper bound on the execution time of a call to the Clock function, in processor clock cycles.

27/2 • Upper bounds on the execution times of the operators of the type CPU_Time, in processor clock cycles.

27.a/2 **Documentation Requirement:** The metrics for execution time.

Implementation Permissions

28/5 {*AI95-00307-01*} {*AI12-0444-1*} Implementations targeted to machines with word size smaller than 32 bits may omit support for the full range and granularity of the CPU_Time type.

Implementation Advice

29/2 {*AI95-00307-01*} When appropriate, implementations should provide configuration mechanisms to change the value of CPU_Tick.

29.a/2 **Implementation Advice:** When appropriate, implementations should provide configuration mechanisms to change the value of Execution_Time.CPU_Tick.

Extensions to Ada 95

29.b/2 {*AI95-00307-01*} The package Execution_Time is new.

Incompatibilities With Ada 2005

29.c/3 {*AI05-0170-1*} Function Clock_For_Interrupts, and constants Interrupt_Clocks_Supported and Separate_Interrupt_Clocks_Supported are added to Execution_Time. If Execution_Time is referenced in a use_clause, and an entity *E* with a defining_identifier of one of the added entities is defined in a package that is also referenced in a use_clause, the entity *E* may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur.

Wording Changes from Ada 2005

{*AI05-0170-1*} If Interrupt_Clocks_Supported is True, it is now possible to determine the execution time of interrupt handlers. This is not an inconsistency, as not charging any task for such time was a legitimate implementation for Ada 2005. 29.d/3

D.14.1 Execution Time Timers

{*AI95-00307-01*} {*AI05-0299-1*} This subclause describes a language-defined package that provides a facility for calling a handler when a task has used a defined amount of CPU time. 1/3

Static Semantics

{*AI95-00307-01*} The following language-defined library package exists: 2/2

```
{AI12-0241-1} {AI12-0302-1} with System;                                    3/5
package Ada.Execution_Time.Timers
   with Nonblocking, Global => in out synchronized is

   type Timer (T : not null access constant                                 4/2
                   Ada.Task_Identification.Task_Id) is
      tagged limited private;

{AI12-0241-1}    type Timer_Handler is                                      5/5
      access protected procedure (TM : in out Timer)
      with Nonblocking => False;

   Min_Handler_Ceiling : constant System.Any_Priority :=                    6/2
   implementation-defined;

   procedure Set_Handler (TM      : in out Timer;                           7/2
                          In_Time : in Time_Span;
                          Handler : in Timer_Handler);
   procedure Set_Handler (TM      : in out Timer;
                          At_Time : in CPU_Time;
                          Handler : in Timer_Handler);
   function Current_Handler (TM : Timer) return Timer_Handler;
   procedure Cancel_Handler (TM        : in out Timer;
                             Cancelled :    out Boolean);

   function Time_Remaining (TM : Timer) return Time_Span;                   8/2

   Timer_Resource_Error : exception;                                        9/2

private                                                                     10/2
   ... -- not specified by the language
end Ada.Execution_Time.Timers;
```

{*AI95-00307-01*} The type Timer represents an execution-time event for a single task and is capable of detecting execution-time overruns. The access discriminant T identifies the task concerned. The type Timer needs finalization (see 7.6). 11/2

{*AI95-00307-01*} An object of type Timer is said to be *set* if it is associated with a nonnull value of type Timer_Handler and *cleared* otherwise. All Timer objects are initially cleared. 12/2

{*AI95-00307-01*} The type Timer_Handler identifies a protected procedure to be executed by the implementation when the timer expires. Such a protected procedure is called a *handler*. 13/2

Discussion: Type Timer is tagged. This makes it possible to share a handler between several events. In simple cases, 'Access can be used to compare the parameter with a specific timer object (this works because a tagged type is a by-reference type). In more complex cases, a type extension of type Timer can be declared; a double type conversion can be used to access the extension data. An example of how this can be done can be found for the similar type Timing_Event, see D.15. 13.a/2

Dynamic Semantics

{*AI95-00307-01*} When a Timer object is created, or upon the first call of a Set_Handler procedure with the timer as parameter, the resources required to operate an execution-time timer based on the associated 14/2

execution-time clock are allocated and initialized. If this operation would exceed the available resources, Timer_Resource_Error is raised.

15/3 {*AI95-00307-01*} {*AI05-0264-1*} The procedures Set_Handler associate the handler Handler with the timer TM: if Handler is **null**, the timer is cleared; otherwise, it is set. The first procedure Set_Handler loads the timer TM with an interval specified by the Time_Span parameter. In this mode, the timer TM *expires* when the execution time of the task identified by TM.T.**all** has increased by In_Time; if In_Time is less than or equal to zero, the timer expires immediately. The second procedure Set_Handler loads the timer TM with the absolute value specified by At_Time. In this mode, the timer TM expires when the execution time of the task identified by TM.T.**all** reaches At_Time; if the value of At_Time has already been reached when Set_Handler is called, the timer expires immediately.

15.a/2 **Implementation Note:** Since an access-to-constant can designate a variable, the Task_Id value designated by the discriminant of a Timer object can be changed after the object is created. Thus, an implementation cannot use the value of the Task_Id other than where this Reference Manual specifies. For instance, the Task_Id should be read when the timer is set, but it should not be used when the timer expires (as it may designate a different task at that point).

16/2 {*AI95-00307-01*} A call of a procedure Set_Handler for a timer that is already set replaces the handler and the (absolute or relative) execution time; if Handler is not **null**, the timer remains set.

17/2 {*AI95-00307-01*} When a timer expires, the associated handler is executed, passing the timer as parameter. The initial action of the execution of the handler is to clear the event.

18/3 {*AI95-00307-01*} {*AI05-0264-1*} The function Current_Handler returns the handler associated with the timer TM if that timer is set; otherwise, it returns **null**.

19/3 {*AI95-00307-01*} {*AI05-0264-1*} The procedure Cancel_Handler clears the timer if it is set. Cancelled is assigned True if the timer was set prior to it being cleared; otherwise, it is assigned False.

20/3 {*AI95-00307-01*} {*AI05-0264-1*} The function Time_Remaining returns the execution time interval that remains until the timer TM would expire, if that timer is set; otherwise, it returns Time_Span_Zero.

21/2 {*AI95-00307-01*} The constant Min_Handler_Ceiling is the minimum ceiling priority required for a protected object with a handler to ensure that no ceiling violation will occur when that handler is invoked.

22/2 {*AI95-00307-01*} As part of the finalization of an object of type Timer, the timer is cleared.

23/2 {*AI95-00307-01*} For all the subprograms defined in this package, Tasking_Error is raised if the task identified by TM.T.**all** has terminated, and Program_Error is raised if the value of TM.T.**all** is Task_Identification.Null_Task_Id.

24/2 {*AI95-00307-01*} An exception propagated from a handler invoked as part of the expiration of a timer has no effect.

Erroneous Execution

25/2 {*AI95-00307-01*} For a call of any of the subprograms defined in this package, if the task identified by TM.T.**all** no longer exists, the execution of the program is erroneous.

Implementation Requirements

26/2 {*AI95-00307-01*} For a given Timer object, the implementation shall perform the operations declared in this package atomically with respect to any of these operations on the same Timer object. The replacement of a handler by a call of Set_Handler shall be performed atomically with respect to the execution of the handler.

26.a/2 **Reason:** This prevents various race conditions. In particular it ensures that if an event occurs when Set_Handler is changing the handler then either the new or old handler is executed in response to the appropriate event. It is never possible for a new handler to be executed in response to an old event

{*AI95-00307-01*} When an object of type Timer is finalized, the system resources used by the timer shall be deallocated. 27/2

Implementation Permissions

{*AI95-00307-01*} {*AI05-0264-1*} Implementations may limit the number of timers that can be defined for each task. If this limit is exceeded, then Timer_Resource_Error is raised. 28/3

NOTE {*AI95-00307-01*} A Timer_Handler can be associated with several Timer objects. 29/2

Extensions to Ada 95

{*AI95-00307-01*} The package Execution_Time.Timers is new. 29.a/2

D.14.2 Group Execution Time Budgets

{*AI95-00354-01*} {*AI05-0299-1*} This subclause describes a language-defined package to assign execution time budgets to groups of tasks. 1/3

Static Semantics

{*AI95-00354-01*} The following language-defined library package exists: 2/2

```
{AI05-0169-1} {AI12-0241-1} {AI12-0302-1} with System;                                    3/5
with System.Multiprocessors;
package Ada.Execution_Time.Group_Budgets
  with Nonblocking, Global => in out synchronized is

{AI05-0092-1} {AI05-0169-1}   type Group_Budget(CPU : System.Multiprocessors.CPU :=       4/3
                                System.Multiprocessors.CPU'First)
    is tagged limited private;

{AI12-0241-1}   type Group_Budget_Handler is access                                       5/5
       protected procedure (GB : in out Group_Budget)
       with Nonblocking => False;

  type Task_Array is array (Positive range <>) of                                         6/2
                                Ada.Task_Identification.Task_Id;

  Min_Handler_Ceiling : constant System.Any_Priority :=                                   7/2
    implementation-defined;
```

Implementation defined: The value of Min_Handler_Ceiling in Execution_Time.Group_Budgets. 7.a.1/3

```
  procedure Add_Task (GB : in out Group_Budget;                                           8/2
                      T  : in Ada.Task_Identification.Task_Id);
  procedure Remove_Task (GB: in out Group_Budget;
                         T  : in Ada.Task_Identification.Task_Id);
  function Is_Member (GB : Group_Budget;
                      T : Ada.Task_Identification.Task_Id) return Boolean;
  function Is_A_Group_Member
     (T : Ada.Task_Identification.Task_Id) return Boolean;
  function Members (GB : Group_Budget) return Task_Array;

  procedure Replenish (GB : in out Group_Budget; To : in Time_Span);                      9/2
  procedure Add (GB : in out Group_Budget; Interval : in Time_Span);
  function Budget_Has_Expired (GB : Group_Budget) return Boolean;
  function Budget_Remaining (GB : Group_Budget) return Time_Span;

  procedure Set_Handler (GB      : in out Group_Budget;                                  10/2
                         Handler : in Group_Budget_Handler);
  function Current_Handler (GB : Group_Budget)
     return Group_Budget_Handler;
  procedure Cancel_Handler (GB        : in out Group_Budget;
                            Cancelled : out Boolean);

  Group_Budget_Error : exception;                                                         11/2
```

12/2
```
private
   -- not specified by the language
end Ada.Execution_Time.Group_Budgets;
```

13/2 {*AI95-00354-01*} The type Group_Budget represents an execution time budget to be used by a group of tasks. The type Group_Budget needs finalization (see 7.6). A task can belong to at most one group. Tasks of any priority can be added to a group.

14/2 {*AI95-00354-01*} An object of type Group_Budget has an associated nonnegative value of type Time_Span known as its *budget*, which is initially Time_Span_Zero. The type Group_Budget_Handler identifies a protected procedure to be executed by the implementation when the budget is *exhausted*, that is, reaches zero. Such a protected procedure is called a *handler*.

15/2 {*AI95-00354-01*} An object of type Group_Budget also includes a handler, which is a value of type Group_Budget_Handler. The handler of the object is said to be *set* if it is not null and *cleared* otherwise. The handler of all Group_Budget objects is initially cleared.

15.a/2 **Discussion:** Type Group_Budget is tagged. This makes it possible to share a handler between several events. In simple cases, 'Access can be used to compare the parameter with a specific group budget object (this works because a tagged type is a by-reference type). In more complex cases, a type extension of type Group_Budget can be declared; a double type conversion can be used to access the extension data. An example of how this can be done can be found for the similar type Timing_Event, see D.15.

Dynamic Semantics

16/2 {*AI95-00354-01*} The procedure Add_Task adds the task identified by T to the group GB; if that task is already a member of some other group, Group_Budget_Error is raised.

17/2 {*AI95-00354-01*} The procedure Remove_Task removes the task identified by T from the group GB; if that task is not a member of the group GB, Group_Budget_Error is raised. After successful execution of this procedure, the task is no longer a member of any group.

18/3 {*AI95-00354-01*} {*AI05-0264-1*} The function Is_Member returns True if the task identified by T is a member of the group GB; otherwise, it returns False.

19/3 {*AI95-00354-01*} {*AI05-0264-1*} The function Is_A_Group_Member returns True if the task identified by T is a member of some group; otherwise, it returns False.

20/2 {*AI95-00354-01*} The function Members returns an array of values of type Task_Identification.Task_Id identifying the members of the group GB. The order of the components of the array is unspecified.

21/3 {*AI95-00354-01*} {*AI05-0092-1*} {*AI05-0169-1*} The procedure Replenish loads the group budget GB with To as the Time_Span value. The exception Group_Budget_Error is raised if the Time_Span value To is nonpositive. Any execution on CPU of any member of the group of tasks results in the budget counting down, unless exhausted. When the budget becomes exhausted (reaches Time_Span_Zero), the associated handler is executed if the handler of group budget GB is set. Nevertheless, the tasks continue to execute.

22/2 {*AI95-00354-01*} The procedure Add modifies the budget of the group GB. A positive value for Interval increases the budget. A negative value for Interval reduces the budget, but never below Time_Span_Zero. A zero value for Interval has no effect. A call of procedure Add that results in the value of the budget going to Time_Span_Zero causes the associated handler to be executed if the handler of the group budget GB is set.

23/3 {*AI95-00354-01*} {*AI05-0264-1*} The function Budget_Has_Expired returns True if the budget of group GB is exhausted (equal to Time_Span_Zero); otherwise, it returns False.

24/2 {*AI95-00354-01*} The function Budget_Remaining returns the remaining budget for the group GB. If the budget is exhausted it returns Time_Span_Zero. This is the minimum value for a budget.

{*AI95-00354-01*} {*AI05-0264-1*} The procedure Set_Handler associates the handler Handler with the Group_Budget GB: if Handler is **null**, the handler of Group_Budget is cleared; otherwise, it is set. 25/3

{*AI95-00354-01*} A call of Set_Handler for a Group_Budget that already has a handler set replaces the handler; if Handler is not **null**, the handler for Group_Budget remains set. 26/2

{*AI95-00354-01*} {*AI05-0264-1*} The function Current_Handler returns the handler associated with the group budget GB if the handler for that group budget is set; otherwise, it returns **null**. 27/3

{*AI95-00354-01*} {*AI05-0264-1*} The procedure Cancel_Handler clears the handler for the group budget if it is set. Cancelled is assigned True if the handler for the group budget was set prior to it being cleared; otherwise, it is assigned False. 28/3

{*AI95-00354-01*} The constant Min_Handler_Ceiling is the minimum ceiling priority required for a protected object with a handler to ensure that no ceiling violation will occur when that handler is invoked. 29/2

{*AI95-00354-01*} The precision of the accounting of task execution time to a Group_Budget is the same as that defined for execution-time clocks from the parent package. 30/2

{*AI95-00354-01*} As part of the finalization of an object of type Group_Budget all member tasks are removed from the group identified by that object. 31/2

{*AI95-00354-01*} {*AI05-0264-1*} If a task is a member of a Group_Budget when it terminates, then as part of the finalization of the task it is removed from the group. 32/3

{*AI95-00354-01*} For all the operations defined in this package, Tasking_Error is raised if the task identified by T has terminated, and Program_Error is raised if the value of T is Task_Identification.Null_Task_Id. 33/2

{*AI95-00354-01*} An exception propagated from a handler invoked when the budget of a group of tasks becomes exhausted has no effect. 34/2

Erroneous Execution

{*AI95-00354-01*} For a call of any of the subprograms defined in this package, if the task identified by T no longer exists, the execution of the program is erroneous. 35/2

Implementation Requirements

{*AI95-00354-01*} For a given Group_Budget object, the implementation shall perform the operations declared in this package atomically with respect to any of these operations on the same Group_Budget object. The replacement of a handler, by a call of Set_Handler, shall be performed atomically with respect to the execution of the handler. 36/2

Reason: This prevents various race conditions. In particular it ensures that if the budget is exhausted when Set_Handler is changing the handler then either the new or old handler is executed and the exhausting event is not lost. 36.a/2

NOTE 1 {*AI95-00354-01*} Clearing or setting of the handler of a group budget does not change the current value of the budget. Exhaustion or loading of a budget does not change whether the handler of the group budget is set or cleared. 37/2

NOTE 2 {*AI95-00354-01*} A Group_Budget_Handler can be associated with several Group_Budget objects. 38/2

Extensions to Ada 95

{*AI95-00354-01*} The package Execution_Time.Group_Budgets is new. 38.a/2

Inconsistencies With Ada 2005

{*AI05-0169-1*} A Group_Budget is now defined to work on a single processor. If an implementation managed to make this package work for programs running on a multiprocessor system, and a program depends on that fact, it could fail when ported to Ada 2012. We believe it is unlikely that such an implementation exists because of the difficulty of 38.b/3

signalling other processors when the time reaches zero; in any case, depending on such an implementation is not portable.

D.14.3 Execution Time of Interrupt Handlers

1/3 {*AI05-0170-1*} {*AI05-0299-1*} This subclause describes a language-defined package to measure the execution time of interrupt handlers.

Static Semantics

2/3 {*AI05-0170-1*} The following language-defined library package exists:

3/5
```
{AI12-0241-1} {AI12-0302-1} with Ada.Interrupts;
package Ada.Execution_Time.Interrupts
   with Nonblocking, Global => in out synchronized is
   function Clock (Interrupt : Ada.Interrupts.Interrupt_Id)
        return CPU_Time;
   function Supported (Interrupt : Ada.Interrupts.Interrupt_Id)
        return Boolean;
end Ada.Execution_Time.Interrupts;
```

4/3 {*AI05-0170-1*} The execution time or CPU time of a given interrupt Interrupt is defined as the time spent by the system executing interrupt handlers identified by Interrupt, including the time spent executing run-time or system services on its behalf. The mechanism used to measure execution time is implementation defined. Time spent executing interrupt handlers is distinct from time spent executing any task.

4.a/3 **Discussion:** The implementation-defined mechanism here is the same as that covered by the Documentation Requirements of D.14, so we don't repeat that requirement here.

5/3 {*AI05-0170-1*} For each interrupt, the execution time value is initially set to zero.

Dynamic Semantics

6/3 {*AI05-0170-1*} The function Clock returns the current cumulative execution time of the interrupt identified by Interrupt. If Separate_Interrupt_Clocks_Supported is set to False the function raises Program_Error.

7/3 {*AI05-0170-1*} {*AI05-0264-1*} The function Supported returns True if the implementation is monitoring the execution time of the interrupt identified by Interrupt; otherwise, it returns False. For any Interrupt_Id Interrupt for which Supported(Interrupt) returns False, the function Clock(Interrupt) will return a value equal to Ada.Execution_Time.Time_Of(0).

Extensions to Ada 2005

7.a/3 {*AI05-0170-1*} The package Execution_Time.Interrupts is new.

D.15 Timing Events

1/5 {*AI95-00297-01*} {*AI05-0299-1*} {*AI12-0445-1*} This subclause describes a language-defined package to allow user-defined protected procedures to be executed at a specified time without the use of a task or a delay statement.

Static Semantics

2/2 {*AI95-00297-01*} The following language-defined library package exists:

3/5
```
{AI12-0241-1} {AI12-0302-1} package Ada.Real_Time.Timing_Events
  with Nonblocking, Global => in out synchronized is
```

```
{AI12-0241-1}   type Timing_Event is tagged limited private;                    4/5
  type Timing_Event_Handler
       is access protected procedure (Event : in out Timing_Event)
       with Nonblocking => False;

  procedure Set_Handler (Event   : in out Timing_Event;                         5/2
                         At_Time : in Time;
                         Handler : in Timing_Event_Handler);
  procedure Set_Handler (Event   : in out Timing_Event;
                         In_Time : in Time_Span;
                         Handler : in Timing_Event_Handler);
  function Current_Handler (Event : Timing_Event)
       return Timing_Event_Handler;
  procedure Cancel_Handler (Event     : in out Timing_Event;
                            Cancelled : out Boolean);

  function Time_Of_Event (Event : Timing_Event) return Time;                    6/2

private                                                                         7/2
   ... -- not specified by the language
end Ada.Real_Time.Timing_Events;
```

{*AI95-00297-01*} The type Timing_Event represents a time in the future when an event is to occur. The type Timing_Event needs finalization (see 7.6). 8/2

{*AI95-00297-01*} An object of type Timing_Event is said to be *set* if it is associated with a nonnull value of type Timing_Event_Handler and *cleared* otherwise. All Timing_Event objects are initially cleared. 9/2

{*AI95-00297-01*} The type Timing_Event_Handler identifies a protected procedure to be executed by the implementation when the timing event occurs. Such a protected procedure is called a *handler*. 10/2

Discussion: Type Timing_Event is tagged. This makes it possible to share a handler between several events. In simple cases, 'Access can be used to compare the parameter with a specific timing event object (this works because a tagged type is a by-reference type). In more complex cases, a type extension of type Timing_Event can be declared; a double type conversion can be used to access the extension data. For example: 10.a/2

```
type Toaster_Timing_Event is new Timing_Event with record                       10.b/2
   Slot : Natural;
end record;

...                                                                             10.c/2

protected body Toaster is                                                       10.d/2

   procedure Timer (Event : in out Timing_Event) is                             10.e/2
   begin
      Pop_Up_Toast (Toaster_Timing_Event(Timing_Event'Class(Event)).Slot);
   end Timer;

   ...                                                                          10.f/2
end Toaster;
```

The extra conversion to the class-wide type is necessary to make the conversions legal. While this usage is clearly ugly, we think that the need for this sort of usage will be rare, so we can live with it. It's certainly better than having no way to associate data with an event. 10.g/2

Dynamic Semantics

{*AI95-00297-01*} {*AI05-0264-1*} The procedures Set_Handler associate the handler Handler with the event Event: if Handler is **null**, the event is cleared; otherwise, it is set. The first procedure Set_Handler sets the execution time for the event to be At_Time. The second procedure Set_Handler sets the execution time for the event to be Real_Time.Clock + In_Time. 11/3

{*AI95-00297-01*} A call of a procedure Set_Handler for an event that is already set replaces the handler and the time of execution; if Handler is not **null**, the event remains set. 12/2

{*AI95-00297-01*} As soon as possible after the time set for the event, the handler is executed, passing the event as parameter. The handler is only executed if the timing event is in the set state at the time of execution. The initial action of the execution of the handler is to clear the event. 13/2

13.a/2 **Reason:** The second sentence of this paragraph is because of a potential race condition. The time might expire and yet before the handler is executed, some task could call Cancel_Handler (or equivalently call Set_Handler with a **null** parameter) and thus clear the handler.

14/2 {*AI95-00297-01*} If the Ceiling_Locking policy (see D.3) is in effect when a procedure Set_Handler is called, a check is made that the ceiling priority of Handler.**all** is Interrupt_Priority'Last. If the check fails, Program_Error is raised.

15/3 {*AI95-00297-01*} {*AI05-0094-1*} {*AI05-0264-1*} If a procedure Set_Handler is called with zero or negative In_Time or with At_Time indicating a time in the past, then the handler is executed as soon as possible after the completion of the call of Set_Handler.

15.a/3 **Ramification:** {*AI05-0094-1*} The handler will still be executed. Under no circumstances is a scheduled call of a handler lost.

15.b/3 **Discussion:** {*AI05-0094-1*} We say “as soon as possible” so that we do not deadlock if we are executing the handler when Set_Handler is called. In that case, the current invocation of the handler must complete before the new handler can start executing.

16/3 {*AI95-00297-01*} {*AI05-0264-1*} The function Current_Handler returns the handler associated with the event Event if that event is set; otherwise, it returns **null**.

17/3 {*AI95-00297-01*} {*AI05-0264-1*} The procedure Cancel_Handler clears the event if it is set. Cancelled is assigned True if the event was set prior to it being cleared; otherwise, it is assigned False.

18/3 {*AI95-00297-01*} {*AI05-0264-1*} The function Time_Of_Event returns the time of the event if the event is set; otherwise, it returns Real_Time.Time_First.

19/2 {*AI95-00297-01*} As part of the finalization of an object of type Timing_Event, the Timing_Event is cleared.

19.a/2 **Implementation Note:** This is the only finalization defined by the language that has a visible effect; but an implementation may have other finalization that it needs to perform. Implementations need to ensure that the event is cleared before anything else is finalized that would prevent a set event from being triggered.

20/2 {*AI95-00297-01*} If several timing events are set for the same time, they are executed in FIFO order of being set.

21/2 {*AI95-00297-01*} An exception propagated from a handler invoked by a timing event has no effect.

Implementation Requirements

22/2 {*AI95-00297-01*} For a given Timing_Event object, the implementation shall perform the operations declared in this package atomically with respect to any of these operations on the same Timing_Event object. The replacement of a handler by a call of Set_Handler shall be performed atomically with respect to the execution of the handler.

22.a/2 **Reason:** This prevents various race conditions. In particular it ensures that if an event occurs when Set_Handler is changing the handler then either the new or old handler is executed in response to the appropriate event. It is never possible for a new handler to be executed in response to an old event.

Metrics

23/2 {*AI95-00297-01*} The implementation shall document the following metric:

24/3 - {*AI05-0210-1*} An upper bound on the lateness of the execution of a handler. That is, the maximum time between the time specified for the event and when a handler is actually invoked assuming no other handler or task is executing during this interval.

24.a/2 **Documentation Requirement:** The metrics for timing events.

Implementation Advice

{*AI95-00297-01*} The protected handler procedure should be executed directly by the real-time clock interrupt mechanism. 25/2

Implementation Advice: For a timing event, the handler should be executed directly by the real-time clock interrupt mechanism. 25.a/2

NOTE 1 {*AI95-00297-01*} Since a call of Set_Handler is not a potentially blocking operation, it can be called from within a handler. 26/2

NOTE 2 {*AI95-00297-01*} A Timing_Event_Handler can be associated with several Timing_Event objects. 27/2

Extensions to Ada 95

{*AI95-00297-01*} The package Real_Time.Timing_Events is new. 27.a/2

Wording Changes from Ada 2005

{*AI05-0094-1*} **Correction:** Reworded to eliminate a deadlock condition if the event time is in the past and a handler is currently executing. This is technically an inconsistency, but only if a program is depending on deadlocking; since it is impossible to imagine how that could be useful, we have not documented this as an inconsistency. 27.b/3

{*AI05-0210-1*} **Correction:** Clarified the metric for lateness of a timing event to exclude interference from other handlers and tasks. This change might change the documentation of an implementation, but not the implementation itself, so there is no inconsistency. 27.c/3

D.16 Multiprocessor Implementation

{*AI05-0171-1*} {*AI05-0299-1*} This subclause allows implementations on multiprocessor platforms to be configured. 1/3

Static Semantics

{*AI05-0171-1*} The following language-defined library package exists: 2/3

```
{AI12-0241-1} {AI12-0302-1} package System.Multiprocessors                    3/5
   with Preelaborate, Nonblocking, Global => in out synchronized is

   type CPU_Range is range 0 .. implementation-defined;                       4/3
   Not_A_Specific_CPU : constant CPU_Range := 0;
   subtype CPU is CPU_Range range 1 .. CPU_Range'Last;
```

Implementation defined: The value of CPU_Range'Last in System.Multiprocessors. 4.a.1/3

```
   function Number_Of_CPUs return CPU;                                        5/3
end System.Multiprocessors;
```

{*AI05-0171-1*} A call of Number_Of_CPUs returns the number of processors available to the program. Within a given partition, each call on Number_Of_CPUs will return the same value. 6/3

{*AI05-0229-1*} {*AI12-0281-1*} For a task type (including the anonymous type of a single_task_declaration), protected type (including the anonymous type of a single_protected_declaration), or subprogram, the following language-defined representation aspect may be specified: 7/5

CPU The aspect CPU is an expression, which shall be of type System.Multiprocessors.CPU_Range. 8/3

Aspect Description for CPU: Processor on which a given task, or calling task for a protected operation, should run. 8.a/5

Legality Rules

{*AI05-0171-1*} {*AI05-0229-1*} If the CPU aspect is specified for a subprogram, the expression shall be static. 9/3

10/5 {*AI05-0229-1*} {*AI12-0281-1*} The CPU aspect shall not be specified on a task or protected interface type.

Dynamic Semantics

11/5 {*AI05-0171-1*} {*AI05-0229-1*} {*AI12-0081-1*} {*AI12-0281-1*} The expression specified for the CPU aspect of a task or protected type is evaluated each time an object of the corresponding type is created (see 9.1 and 9.4). The CPU value is then associated with the object.

12/3 {*AI05-0171-1*} {*AI05-0229-1*} The CPU aspect has no effect if it is specified for a subprogram other than the main subprogram; the CPU value is not associated with any task.

13/3 {*AI05-0171-1*} {*AI05-0229-1*} The CPU value is associated with the environment task if the CPU aspect is specified for the main subprogram. If the CPU aspect is not specified for the main subprogram it is implementation defined on which processor the environment task executes.

13.a.1/3 **Implementation defined:** The processor on which the environment task executes in the absence of a value for the aspect CPU.

14/5 {*AI05-0171-1*} {*AI05-0264-1*} {*AI12-0281-1*} For a task, the CPU value determines the processor on which the task will activate and execute; the task is said to be assigned to that processor. If the CPU value is Not_A_Specific_CPU, then the task is not assigned to a processor. A task without a CPU aspect specified will activate and execute on the same processor as its activating task if the activating task is assigned a processor. If the CPU value is not in the range of System.Multiprocessors.CPU_Range or is greater than Number_Of_CPUs the task is defined to have failed, and it becomes a completed task (see 9.2).

15/5 {*AI12-0281-1*} For a protected type, the CPU value determines the processor on which calling tasks will execute; the protected object is said to be assigned to that processor. If the CPU value is Not_A_Specific_CPU, then the protected object is not assigned to a processor. A call to a protected object that is assigned to a processor from a task that is not assigned a processor or is assigned a different processor raises Program_Error.

15.a/5 **Discussion:** {*AI12-0005-1*} When a protected object is assigned to a CPU, only tasks also assigned to that CPU can call it. In contrast, a protected object that is not assigned to a specific CPU can be called by any task on any processor (subject, of course, to visibility and ceiling priority restrictions). As noted below, when the tasks and protected object are necessarily on the same CPU, a simpler implementation can be used.

Implementation Advice

16/5 {*AI12-0281-1*} {*AI12-0323-1*} Starting a protected action on a protected object statically assigned to a processor should be implemented without busy-waiting.

16.a/5 **Reason:** Busy-waiting is a form of lock and can be a source of deadlock. Busy-waiting is typically needed for starting protected actions on multiprocessors, but if all tasks calling a protected object execute on the same CPU, this locking isn't needed and the source of deadlock and associated overhead can be eliminated.

16.b/5 **Implementation Advice:** Starting a protected action on a protected object statically assigned to a processor should not use busy-waiting.

Extensions to Ada 2005

16.c/3 {*AI05-0171-1*} {*AI05-0229-1*} The package System.Multiprocessors and the CPU aspect are new.

Extensions to Ada 2012

16.d/5 {*AI12-0281-1*} Aspect CPU can now be applied to protected types, in order to avoid the overhead and deadlock potential of multiprocessor execution.

Wording Changes from Ada 2012

16.e/4 {*AI12-0081-1*} **Corrigendum:** Clarified when the CPU aspect expression is evaluated.

D.16.1 Multiprocessor Dispatching Domains

{*AI05-0167-1*} {*AI05-0299-1*} This subclause allows implementations on multiprocessor platforms to be partitioned into distinct dispatching domains during program startup. 1/3

Static Semantics

{*AI05-0167-1*} The following language-defined library package exists: 2/3

```
{AI12-0241-1} {AI12-0302-1} with Ada.Real_Time;                                    3/5
with Ada.Task_Identification;
package System.Multiprocessors.Dispatching_Domains
   with Nonblocking, Global => in out synchronized is

   Dispatching_Domain_Error : exception;                                           4/3

   type Dispatching_Domain (<>) is limited private;                                5/3

   System_Dispatching_Domain : constant Dispatching_Domain;                        6/3

   function Get_CPU                                                                13/3
      (T   : Ada.Task_Identification.Task_Id :=
                Ada.Task_Identification.Current_Task)
           return CPU_Range;

   procedure Delay_Until_And_Set_CPU                                               14/3
      (Delay_Until_Time : in Ada.Real_Time.Time; CPU : in CPU_Range);

private                                                                            15/3
   ... -- not specified by the language
end System.Multiprocessors.Dispatching_Domains;
```

{*AI05-0167-1*} {*AI12-0082-1*} A *dispatching domain* represents a set of processors on which a task may execute. Each processor is contained within exactly one dispatching domain. An object of type Dispatching_Domain identifies a dispatching domain. System_Dispatching_Domain identifies a domain that contains the processor or processors on which the environment task executes. At program start-up all processors are contained within this domain. 16/4

{*AI05-0167-1*} For a task type (including the anonymous type of a single_task_declaration), the following language-defined representation aspect may be specified: 17/3

18/3 Dispatching_Domain

The value of aspect Dispatching_Domain is an expression, which shall be of type Dispatching_Domains.Dispatching_Domain. This aspect is the domain to which the task (or all objects of the task type) are assigned.

18.a/3 **Aspect Description for Dispatching_Domain:** Domain (group of processors) on which a given task should run.

Legality Rules

19/3 {*AI05-0167-1*} The Dispatching_Domain aspect shall not be specified for a task interface.

Dynamic Semantics

20/4 {*AI05-0167-1*} {*AI12-0033-1*} The expression specified for the Dispatching_Domain aspect of a task type is evaluated each time an object of the task type is created (see 9.1). If the identified dispatching domain is empty, then Dispatching_Domain_Error is raised; otherwise the newly created task is assigned to the domain identified by the value of the expression.

21/3 {*AI05-0167-1*} If a task is not explicitly assigned to any domain, it is assigned to that of the activating task. A task always executes on some CPU in its domain.

22/4 {*AI05-0167-1*} {*AI12-0082-1*} If both the dispatching domain and CPU are specified for a task, and the CPU value is not contained within the set of processors for the domain (and is not Not_A_Specific_CPU), the activation of the task is defined to have failed, and it becomes a completed task (see 9.2).

23/4 {*AI05-0167-1*} {*AI12-0033-1*} The function Create with First and Last parameters creates and returns a dispatching domain containing all the processors in the range First .. Last. The function Create with a Set parameter creates and returns a dispatching domain containing the processors for which Set(I) is True. These processors are removed from System_Dispatching_Domain. A call of Create will raise Dispatching_Domain_Error if any designated processor is not currently in System_Dispatching_Domain, or if the system cannot support a distinct domain over the processors identified, or if a processor has a task assigned to it, or if the allocation would leave System_Dispatching_Domain empty. A call of Create will raise Dispatching_Domain_Error if the calling task is not the environment task, or if Create is called after the call to the main subprogram.

24/4 {*AI05-0167-1*} {*AI12-0033-1*} The function Get_First_CPU returns the first CPU in Domain, or CPU'First if Domain is empty; Get_Last_CPU returns the last CPU in Domain, or CPU_Range'First if Domain is empty. The function Get_CPU_Set(D) returns an array whose low bound is Get_First_CPU(D), whose high bound is Get_Last_CPU(D), with True values in the Set corresponding to the CPUs that are in the given Domain.

25/4 {*AI05-0167-1*} {*AI12-0082-1*} The function Get_Dispatching_Domain returns the dispatching domain on which the task is assigned.

26/4 {*AI05-0167-1*} {*AI05-0278-1*} {*AI12-0033-1*} A call of the procedure Assign_Task assigns task T to the CPU within the dispatching domain Domain. Task T can now execute only on CPU, unless CPU designates Not_A_Specific_CPU in which case it can execute on any processor within Domain. The exception Dispatching_Domain_Error is propagated if Domain is empty, T is already assigned to a dispatching domain other than System_Dispatching_Domain, or if CPU is not one of the processors of Domain (and is not Not_A_Specific_CPU). A call of Assign_Task is a task dispatching point for task T unless T is inside of a protected action, in which case the effect on task T is delayed until its next task dispatching point. If T is the Current_Task the effect is immediate if T is not inside a protected action, otherwise the effect is as soon as practical. Assigning a task already assigned to System_Dispatching_Domain to that domain has no effect.

{*AI05-0167-1*} {*AI05-0278-1*} {*AI12-0082-1*} A call of procedure Set_CPU assigns task T to the CPU. Task T can now execute only on CPU, unless CPU designates Not_A_Specific_CPU, in which case it can execute on any processor within its dispatching domain. The exception Dispatching_Domain_Error is propagated if CPU is not one of the processors of the dispatching domain on which T is assigned (and is not Not_A_Specific_CPU). A call of Set_CPU is a task dispatching point for task T unless T is inside of a protected action, in which case the effect on task T is delayed until its next task dispatching point. If T is the Current_Task the effect is immediate if T is not inside a protected action, otherwise the effect is as soon as practical. 27/4

{*AI05-0167-1*} The function Get_CPU returns the processor assigned to task T, or Not_A_Specific_CPU if the task is not assigned to a processor. 28/3

{*AI05-0167-1*} {*AI12-0082-1*} A call of Delay_Until_And_Set_CPU delays the calling task for the designated time and then assigns the task to the specified processor when the delay expires. The exception Dispatching_Domain_Error is propagated if P is not one of the processors of the calling task's dispatching domain (and is not Not_A_Specific_CPU). 29/4

Implementation Requirements

{*AI05-0167-1*} The implementation shall perform the operations Assign_Task, Set_CPU, Get_CPU and Delay_Until_And_Set_CPU atomically with respect to any of these operations on the same dispatching_domain, processor or task. 30/3

{*AI12-0048-1*} Any task that belongs to the system dispatching domain can execute on any CPU within that domain, unless the assignment of the task has been specified. 30.1/4

Reason: This ensures that priorities and deadlines are respected within the system dispatching domain. There is no such guarantee between different domains. 30.a/4

We only need to talk about the system dispatching domain here, because Assign_Task and Set_CPU already have such wording for tasks that are assigned explicitly to a dispatching domain and specify Not_a_Specific_CPU. 30.b/4

Ramification: If no dispatching domains are created, all tasks can execute on all processors. (As always, implementation-defined dispatching policies may have other rules, so a partition that does not specify any language-defined dispatching policy may do anything at all and in particular does not need to follow this rule. 30.c/4

Discussion: A task can be assigned to a specific CPU by specifying the aspect CPU for a task, or by calling a dynamic operation like Set_CPU or Assign_Task. 30.d/4

Implementation Advice

{*AI05-0167-1*} Each dispatching domain should have separate and disjoint ready queues. 31/3

Implementation Advice: Each dispatching domain should have separate and disjoint ready queues. 31.a/3

To be honest: {*AI12-0048-1*} “Ready queue” here doesn't mean the conceptual "ready queue" as defined in D.2.1 (one per processor); this rule is talking about the ready queues used by the implementation. 31.b/4

Documentation Requirements

{*AI05-0167-1*} The implementation shall document the processor(s) on which the clock interrupt is handled and hence where delay queue and ready queue manipulations occur. For any Interrupt_Id whose handler can execute on more than one processor the implementation shall also document this set of processors. 32/3

Documentation Requirement: The processor(s) on which the clock interrupt is handled; the processors on which each Interrupt_Id can be handled. 32.a/3

Implementation Permissions

{*AI05-0167-1*} An implementation may limit the number of dispatching domains that can be created and raise Dispatching_Domain_Error if an attempt is made to exceed this number. 33/3

34/5 {*AI12-0119-1*} The implementation may defer the effect of a Set_CPU or an Assign_Task operation until the specified task leaves an ongoing parallel construct.

34.a/5 **Reason:** {*AI12-0119-1*} These operations can change the set of CPUs that a parallel operation is allowed to use. This could require the ability to move or suspend one or more threads to execute them on a different CPU. However, parallel constructs are primarily intended to improve performance of code, and the overhead needed to support such a rarely used operation could be substantial. Therefore, rather than requiring support we allow the implementation to wait to implement these operations until the parallel construct (and thus the extra threads) have completed.

Extensions to Ada 2005

34.b/3 {*AI05-0167-1*} {*AI05-0278-1*} The package System.Multiprocessors.Dispatching_Domains and the aspect Dispatching_Domains are new.

Inconsistencies With Ada 2012

34.c/4 {*AI12-0033-1*} **Corrigendum:** We now explicitly allow empty dispatching domains, as it would be difficult to avoid declaring them when a system is configured at runtime. Therefore, assigning a task to an empty domain now raises Dispatching_Domain_Error; creating such a domain should not raise Dispatching_Domain_Error. If an implementation does something different in these cases, and a program depends on that difference, the program could malfunction. This seems very unlikely (if no exception is ever raised, the task assigned to the empty domain could never run; if the exception is raised earlier, the program can't do anything useful).

Incompatibilities With Ada 2012

34.d/5 {*AI05-0033-1*} {*AI05-0005-1*} **Corrigendum:** The subtypes of the parameter or result of several routines were changed to support empty domains. These changes will cause rules requiring subtype conformance to fail on these routines (such as 'Access). We believe such uses are unlikely. In addition, type CPU_Set and function Get_CPU_Set, along with an overloaded Create are newly added to this package. As such, a use clause conflict is possible; see the introduction of Annex A for more on this topic.

Wording Changes from Ada 2012

34.e/4 {*AI12-0048-1*} **Corrigendum:** Added wording to clarify that all tasks can execute on all CPUs of the system dispatching domain by default.

34.f/4 {*AI12-0082-1*} **Corrigendum:** Added a definition to clarify that a "dispatching domain" is a concept which is identified by an object of type Dispatching_Domain; more than one object might identify the same dispatching domain (for instance, the result of function Get_Dispatching_Domain is a different object but identifies the same dispatching domain).

Annex E
(normative)
Distributed Systems

[This Annex defines facilities for supporting the implementation of distributed systems using multiple partitions working cooperatively as part of a single Ada program.] 1

Extensions to Ada 83

This Annex is new to Ada 95. 1.a

Post-Compilation Rules

A *distributed system* is an interconnection of one or more *processing nodes* (a system resource that has both computational and storage capabilities), and zero or more *storage nodes* (a system resource that has only storage capabilities, with the storage addressable by one or more processing nodes). 2

A *distributed program* comprises one or more partitions that execute independently (except when they communicate) in a distributed system. 3

The process of mapping the partitions of a program to the nodes in a distributed system is called *configuring the partitions of the program*. 4

Implementation Requirements

The implementation shall provide means for explicitly assigning library units to a partition and for the configuring and execution of a program consisting of multiple partitions on a distributed system; the means are implementation defined. 5

Implementation defined: The means for creating and executing distributed programs. 5.a

Implementation Permissions

An implementation may require that the set of processing nodes of a distributed system be homogeneous. 6

NOTE 1 {*AI12-0440-1*} The partitions comprising a program can be executed on differently configured distributed systems or on a nondistributed system without requiring recompilation. A distributed program can be partitioned differently from the same set of library units without recompilation. The resulting execution is semantically equivalent. 7/5

NOTE 2 A distributed program retains the same type safety as the equivalent single partition program. 8

E.1 Partitions

[The partitions of a distributed program are classified as either active or passive.] 1

Post-Compilation Rules

An *active partition* is a partition as defined in 10.2. A *passive partition* is a partition that has no thread of control of its own, whose library units are all preelaborated, and whose data and subprograms are accessible to one or more active partitions. 2

Discussion: In most situations, a passive partition does not execute, and does not have a “real” environment task. Any execution involved in its elaboration and initialization occurs before it comes into existence in a distributed program (like most preelaborated entities). Likewise, there is no concrete meaning to passive partition termination. 2.a

A passive partition shall include only library_items that either are declared pure or are shared passive (see 10.2.1 and E.2.1). 3

4 An active partition shall be configured on a processing node. A passive partition shall be configured either on a storage node or on a processing node.

5 The configuration of the partitions of a program onto a distributed system shall be consistent with the possibility for data references or calls between the partitions implied by their semantic dependences. Any reference to data or call of a subprogram across partitions is called a *remote access*.

5.a **Discussion:** For example, an active partition that includes a unit with a semantic dependence on the declaration of another RCI package of some other active partition has to be connected to that other partition by some sort of a message passing mechanism.

5.b A passive partition that is accessible to an active partition should have its storage addressable to the processor(s) of the active partition. The processor(s) should be able to read and write from/to that storage, as well as to perform "read-modify-write" operations (in order to support entry-less protected objects).

5.c/5 **Ramification:** {*AI12-0359-1*} A passive partition has no execution resources of its own, so while a call of a subprogram in a passive partition is a remote access to that subprogram, it is *not* a remote subprogram call (see E.4). The calling active partition executes the body of the subprogram of the passive partition.

Dynamic Semantics

6 A library_item is elaborated as part of the elaboration of each partition that includes it. If a normal library unit (see E.2) has state, then a separate copy of the state exists in each active partition that elaborates it. [The state evolves independently in each such partition.]

6.a **Ramification:** Normal library units cannot be included in passive partitions.

7 [An active partition *terminates* when its environment task terminates.] A partition becomes *inaccessible* if it terminates or if it is *aborted*. An active partition is aborted when its environment task is aborted. In addition, if a partition fails during its elaboration, it becomes inaccessible to other partitions. Other implementation-defined events can also result in a partition becoming inaccessible.

7.a **Implementation defined:** Any events that can result in a partition becoming inaccessible.

8/1 For a prefix D that denotes a library-level declaration, excepting a declaration of or within a declared-pure library unit, the following attribute is defined:

9 D'Partition_Id

Denotes a value of the type *universal_integer* that identifies the partition in which D was elaborated. If D denotes the declaration of a remote call interface library unit (see E.2.3) the given partition is the one where the body of D was elaborated.

Bounded (Run-Time) Errors

10/2 {*AI95-00226-01*} It is a bounded error for there to be cyclic elaboration dependences between the active partitions of a single distributed program. The possible effects, in each of the partitions involved, are deadlock during elaboration, or the raising of Communication_Error or Program_Error.

Implementation Permissions

11 An implementation may allow multiple active or passive partitions to be configured on a single processing node, and multiple passive partitions to be configured on a single storage node. In these cases, the scheduling policies, treatment of priorities, and management of shared resources between these partitions are implementation defined.

11.a **Implementation defined:** The scheduling policies, treatment of priorities, and management of shared resources between partitions in certain cases.

12 An implementation may allow separate copies of an active partition to be configured on different processing nodes, and to provide appropriate interactions between the copies to present a consistent state of the partition to other active partitions.

Ramification: The language does not specify the nature of these interactions, nor the actual level of consistency preserved. 12.a

{*AI12-0444-1*} In an implementation, the partitions of a distributed program may be loaded and elaborated at different times; they may be loaded and elaborated one at a time over an extended period of time. An implementation may provide facilities to abort and reload a partition during the execution of a distributed program. 13/5

An implementation may allow the state of some of the partitions of a distributed program to persist while other partitions of the program terminate and are later reinvoked. 14

NOTE 1 {*AI12-0417-1*} Library units are grouped into partitions after compile time, but before run time. At compile time, only the relevant library unit properties are identified using categorization aspects. 15/5

NOTE 2 The value returned by the Partition_Id attribute can be used as a parameter to implementation-provided subprograms in order to query information about the partition. 16

Wording Changes from Ada 95

{*AI95-00226-01*} Corrected wording so that a partition that has an elaboration problem will either deadlock or raise an exception. While an Ada 95 implementation could allow some partitions to continue to execute, they could be accessing unelaborated data, which is very bad (and erroneous in a practical sense). Therefore, this isn't listed as an inconsistency. 16.a/2

E.2 Categorization of Library Units

[Library units can be categorized according to the role they play in a distributed program. Certain restrictions are associated with each category to ensure that the semantics of a distributed program remain close to the semantics for a nondistributed program.] 1

{*AI05-0243-1*} {*AI12-0417-1*} A *categorization aspect* restricts the declarations, child units, or semantic dependences of the library unit to which it applies. A *categorized library unit* is a library unit that has a categorization aspect that is True. 2/3

{*AI05-0243-1*} {*AI12-0417-1*} The aspects Shared_Passive, Remote_Types, and Remote_Call_Interface are categorization aspects. In addition, for the purposes of this Annex, the aspect Pure (see 10.2.1) is considered a categorization aspect. 3/3

{*8652/0078*} {*AI95-00048-01*} {*AI05-0243-1*} [A library package or generic library package is called a *shared passive* library unit if the Shared_Passive aspect of the unit is True. A library package or generic library package is called a *remote types* library unit if the Remote_Types aspect of the unit is True. A library unit is called a *remote call interface* if the Remote_Call_Interface aspect of the unit is True.] A *normal library unit* is one for which no categorization aspect is True. 4/3

Proof: {*AI05-0243-1*} {*AI05-0299-1*} These terms (other than “normal library unit”) are really defined in the following subclauses. 4.a/3

Ramification: {*8652/0078*} {*AI95-00048-01*} A library subprogram can be a remote call interface, but it cannot be a remote types or shared passive library unit. 4.a.1/1

{*AI05-0206-1*} {*AI05-0243-1*} {*AI05-0269-1*} {*AI05-0299-1*} [The various categories of library units and the associated restrictions are described in this and the following subclauses. The categories are related hierarchically in that the library units of one category can depend semantically only on library units of that category or an earlier one in the hierarchy, except that the body of a remote types or remote call interface library unit is unrestricted, the declaration of a remote types or remote call interface library unit may depend on preelaborated normal library units that are mentioned only in private with clauses, and all categories can depend on limited views. 5/3

{*AI05-0243-1*} {*AI05-0269-1*} The overall hierarchy (including declared pure) is as follows, with a lower-numbered category being “earlier in the hierarchy” in the sense of the previous paragraph: 6/3

6.1/3 1. Declared Pure

6.2/3 2. Shared Passive

6.3/3 3. Remote Types

6.4/3 4. Remote Call Interface

6.5/3 5. Normal (no restrictions)

Paragraphs 7 through 11 were deleted.

12 Declared pure and shared passive library units are preelaborated. The declaration of a remote types or remote call interface library unit is required to be preelaborable.]

Paragraph 13 and 14 were deleted.

Wording Changes from Ada 95

14.a/2 {*8652/0078*} {*AI95-00048-01*} **Corrigendum:** Clarified that a library subprogram can be a remote call interface unit.

14.b/2 {*8652/0079*} {*AI95-00208-01*} **Corrigendum:** Removed the requirement that types be represented the same in all partitions, because it prevents the definition of heterogeneous distributed systems and goes much further than required.

Wording Changes from Ada 2005

14.c/3 {*AI05-0206-1*} {*AI05-0299-1*} We now allow private withs of preelaborated units in Remote Types and Remote Call Interface units; this is documented as an extension in the subclauses where this is defined normatively.

14.d/3 {*AI05-0243-1*} {*AI05-0299-1*} We have introduced categorization aspects; these are documented as extensions in the subclauses where they actually are defined.

Wording Changes from Ada 2012

14.e/5 {*AI12-0417-1*} Categorization pragmas are now obsolescent.

E.2.1 Shared Passive Library Units

1 [A shared passive library unit is used for managing global data shared between active partitions. The restrictions on shared passive library units prevent the data or tasks of one active partition from being accessible to another active partition through references implicit in objects declared in the shared passive library unit.]

Language Design Principles

1.a The restrictions governing a shared passive library unit are designed to ensure that objects and subprograms declared in the package can be used safely from multiple active partitions, even though the active partitions live in different address spaces, and have separate run-time systems.

Paragraphs 2 and 3 were moved to Annex J, "Obsolescent Features".

Legality Rules

4/5 {*AI05-0243-1*} {*AI12-0417-1*} When the library unit aspect (see 13.1.1) Shared_Passive of a library unit is True, the library unit is a *shared passive library unit*. The following restrictions apply to such a library unit:

4.a/3 **Aspect Description for Shared_Passive:** A given package is used to represent shared memory in a distributed system.

5 • [it shall be preelaborable (see 10.2.1);]

5.a **Ramification:** It cannot contain library-level declarations of protected objects with entries, nor of task objects. Task objects are disallowed because passive partitions don't have any threads of control of their own, nor any run-time system of their own. Protected objects with entries are disallowed because an entry queue contains references to calling tasks, and that would require in effect a pointer from a passive partition back to a task in some active partition.

- {*AI05-0243-1*} it shall depend semantically only upon declared pure or shared passive library_items; 6/3

  Reason: Shared passive packages cannot depend semantically upon remote types packages because the values of an access type declared in a remote types package refer to the local heap of the active partition including the remote types package. 6.a

  Ramification: {*AI05-0243-1*} We say library_item here, so that limited views are allowed; those are not library units, but they are library_item. 6.b/3

- {*8652/0080*} {*AI95-00003-01*} {*AI12-0038-1*} {*AI12-0320-1*} it shall not contain a library-level declaration: 7/5

  - {*AI12-0320-1*} of an access type that designates a class-wide type; 7.1/5

    Reason: These kinds of access types are disallowed because the object designated by an access value of such a type could contain an implicit reference back to the active partition on whose behalf the designated object was created. 7.a

  - {*AI12-0320-1*} of a type with a part that is of a task type; 7.2/5

  - {*AI12-0320-1*} of a type with a part that is of a protected type with entry_declarations; or 7.3/5

  - {*AI12-0038-1*} {*AI12-0320-1*} that contains a name that denotes a type declared within a declared-pure package, if that type has a part that is of an access type; for the purposes of this rule, the parts considered include those of the full views of any private types or private extensions. 7.4/5

    Reason: This rule breaks privacy by looking into the full views of private types. Avoiding privacy breakage here would have required disallowing the use in a shared passive package of any private type declared in a declared-pure package, which would have been severely incompatible. 7.b/4

Notwithstanding the definition of accessibility given in 3.10.2, the declaration of a library unit P1 is not accessible from within the declarative region of a shared passive library unit P2, unless the shared passive library unit P2 depends semantically on P1. 8

Discussion: We considered a more complex rule, but dropped it. This is the simplest rule that recognizes that a shared passive package may outlive some other library package, unless it depends semantically on that package. In a nondistributed program, all library packages are presumed to have the same lifetime. 8.a

{*AI12-0417-1*} Implementations may define additional aspects or pragmas that force two library packages to be in the same partition, or to have the same lifetime, which would allow this rule to be relaxed in the presence of such aspects or pragmas. 8.b/5

Static Semantics

A shared passive library unit is preelaborated. 9

Post-Compilation Rules

A shared passive library unit shall be assigned to at most one partition within a given program. 10

Notwithstanding the rule given in 10.2, a compilation unit in a given partition does not *need* (in the sense of 10.2) the shared passive library units on which it depends semantically to be included in that same partition; they will typically reside in separate passive partitions. 11

To be honest: {*AI12-0359-1*} This rule is necessary so that the shared data of a shared passive partition is not duplicated in each partition. It does not imply a particular implementation; in particular, code can be replicated in each active partition. 11.a/5

Implementation Note: {*AI12-0359-1*} One possible implementation for a shared passive partition is as a shared library that is mapped into the address space of of each active partition. In such case, both the code and the data of the passive partition would be mapped into the active partitions and directly called/accessed from each active partition. For instance, on Microsoft Windows a DLL has the correct semantics. 11.b/5

Alternatively, the shared data can be represented as a file or persistent memory, with the shared code being replicated in each active partition. Code replication is an as-if optimization; it should be impossible to tell where the code lives since no elaboration is necessary. 11.c/5

Wording Changes from Ada 95

11.d/2 {*8652/0080*} {*AI95-00003-01*} **Corrigendum:** Corrected the wording to allow access types in blocks in shared passive generic packages.

Extensions to Ada 2005

11.e/5 {*AI05-0243-1*} {*AI12-0417-1*} Shared_Passive is now a categorization aspect, so it can be specified by an aspect_specification

Incompatibilities With Ada 2012

11.f/4 {*AI12-0038-1*} **Corrigendum:** Uses of access types declared in declared-pure units are not allowed in library-level shared passive packages. These were allowed by Ada 2005 and Ada 2012, but it is unlikely that they work properly, as active partitions could disappear before the shared-passive partition. As such, the new errors are more likely to catch bugs than to cause them.

Wording Changes from Ada 2012

11.g/5 {*AI12-0417-1*} The pragma Shared_Passive is now obsolescent.

E.2.2 Remote Types Library Units

1 [A remote types library unit supports the definition of types intended for use in communication between active partitions.]

Language Design Principles

1.a The restrictions governing a remote types package are similar to those for a declared pure package. However, the restrictions are relaxed deliberately to allow such a package to contain declarations that violate the stateless property of pure packages, though it is presumed that any state-dependent properties are essentially invisible outside the package.

Paragraphs 2 and 3 were moved to Annex J, "Obsolescent Features".

Legality Rules

4/5 {*AI05-0243-1*} {*AI12-0417-1*} When the library unit aspect (see 13.1.1) Remote_Types of a library unit is True, the library unit is a *remote types library unit*. The following restrictions apply to such a library unit:

4.a/3 **Aspect Description for Remote_Types:** Types in a given package may be used in remote procedure calls.

5 • [it shall be preelaborable;]

6/3 • {*AI05-0206-1*} {*AI05-0243-1*} it shall depend semantically only on declared pure library_items, shared passive library units, other remote types library units, or preelaborated normal library units that are mentioned only in private with clauses;

6.a/3 **Ramification:** {*AI05-0243-1*} We say declared pure library_item here, so that (all) limited views are allowed; those are not library units, but they are declared pure library_items.

7 • it shall not contain the declaration of any variable within the visible part of the library unit;

7.a **Reason:** This is essentially a "methodological" restriction. A separate copy of a remote types package is included in each partition that references it, just like a normal package. Nevertheless, a remote types package is thought of as an "essentially pure" package for defining types to be used for interpartition communication, and it could be misleading to declare visible objects when no remote data access is actually being provided.

8/2 • {*AI95-00240-01*} {*AI95-00366-01*} the full view of each type declared in the visible part of the library unit that has any available stream attributes shall support external streaming (see 13.13.2).

8.a **Reason:** This is to prevent the use of the predefined Read and Write attributes of an access type as part of the Read and Write attributes of a visible type.

8.b/2 **Ramification:** {*AI95-00366-01*} Types that do not have available stream attributes are excluded from this rule; that means that attributes do not need to be specified for most limited types. It is only necessary to specify attributes for nonlimited types that have a part that is of any access type, and for extensions of limited types with available stream

attributes where the record_extension_part includes a subcomponent of an access type, where the access type does not have specified attributes.

{*8652/0082*} {*AI95-00164-01*} {*AI05-0060-1*} A named access type declared in the visible part of a remote types or remote call interface library unit is called a *remote access type*. Such a type shall be: 9/3

- {*8652/0082*} {*AI95-00164-01*} an access-to-subprogram type, or 9.1/1
- {*8652/0082*} {*AI95-00164-01*} {*AI05-0060-1*} a general access type that designates a class-wide limited private type, a class-wide limited interface type, or a class-wide private extension all of whose ancestors are either private extensions, limited interface types, or limited private types. 9.2/3

{*8652/0081*} {*AI95-00004-01*} A type that is derived from a remote access type is also a remote access type. 9.3/1

{*AI12-0283-1*} A remote access-to-subprogram type shall not be nonblocking (see 9.5). 9.4/5

Reason: All calls on remote subprograms are considered potentially blocking, so they cannot statically be allowed in nonblocking code. 9.a/5

Ramification: The type declaration of a remote type is illegal if the Nonblocking aspect is True, either implicitly by inheritance or by explicit specification. 9.b/5

The following restrictions apply to the use of a remote access-to-subprogram type: 10

- {*AI95-00431-01*} A value of a remote access-to-subprogram type shall be converted only to or from another (subtype-conformant) remote access-to-subprogram type; 11/2
- The prefix of an Access attribute_reference that yields a value of a remote access-to-subprogram type shall statically denote a (subtype-conformant) remote subprogram. 12

The following restrictions apply to the use of a remote access-to-class-wide type: 13

- {*8652/0083*} {*AI95-00047-01*} {*AI95-00240-01*} {*AI95-00366-01*} {*AI05-0060-1*} {*AI05-0101-1*} The primitive subprograms of the corresponding specific type shall only have access parameters if they are controlling formal parameters. The primitive functions of the corresponding specific type shall only have an access result if it is a controlling access result. Each noncontrolling formal parameter and noncontrolling result type shall support external streaming (see 13.13.2); 14/3
- {*AI05-0060-1*} {*AI05-0215-1*} {*AI05-0269-1*} The corresponding specific type shall not have a primitive procedure with the Synchronization aspect specified unless the synchronization_kind is Optional (see 9.5); 14.1/3
- A value of a remote access-to-class-wide type shall be explicitly converted only to another remote access-to-class-wide type; 15
- {*AI12-0034-1*} A value of a remote access-to-class-wide type shall be dereferenced (or implicitly converted to an anonymous access type) only as part of a dispatching call to a primitive operation of the designated type where the value designates a controlling operand of the call (see E.4, “Remote Subprogram Calls”); 16/4

  Ramification: {*AI12-0034-1*} Stream attributes of the designated type are not primitive operations of the designated type, and thus remote calls to them are prohibited by this rule. This is good, as the access parameter of a stream attribute does not have external streaming, and thus cannot be a parameter of a remote call. 16.a/4
- {*AI05-0101-1*} A controlling access result value for a primitive function with any controlling operands of the corresponding specific type shall either be explicitly converted to a remote access-to-class-wide type or be part of a dispatching call where the value designates a controlling operand of the call; 16.1/3
- {*AI95-00366-01*} {*AI12-0085-1*} The Storage_Pool attribute is not defined for a remote access-to-class-wide type; the expected type for an allocator shall not be a remote access-to-class-wide type. A remote access-to-class-wide type shall not be an actual parameter for a generic formal access type. The Storage_Size attribute of a remote access-to-class-wide type yields 0. The 17/4

Storage_Pool and Storage_Size aspects shall not be specified for a remote access-to-class-wide type.

17.a/3 **Reason:** {*AI05-0005-1*} All of these restrictions are because there is no storage pool associated with a remote access-to-class-wide type. The Storage_Size is defined to be 0 so that there is no conflict with the rules for pure units.

17.b/4 **Ramification:** {*AI12-0085-1*} The prohibition against specifying the Storage_Size aspect for an access-to-class-wide type applies to any method of doing that, including via either an aspect_specification or an attribute_definition_clause.

Erroneous Execution

17.1/4 {*AI12-0076-1*} Execution is erroneous if some operation (other than the initialization or finalization of the object) modifies the value of a constant object declared in the visible part of a remote types package.

17.c/4 **Discussion:** {*AI12-0005-1*} This could be accomplished via a self-referencing pointer or via squirrelling away a writable pointer to a controlled object.

18/5 NOTE 1 {*AI12-0442-1*} A remote types library unit is not necessarily pure, and the types it defines can include levels of indirection implemented by using access types. User-specified Read and Write attributes (see 13.13.2) provide for sending values of such a type between active partitions, with Write marshalling the representation, and Read unmarshalling any levels of indirection.

19/3 NOTE 2 {*AI05-0060-1*} The value of a remote access-to-class-wide limited interface can designate an object of a nonlimited type derived from the interface.

20/5 NOTE 3 {*AI05-0060-1*} {*AI12-0440-1*} A remote access type can designate a class-wide synchronized, protected, or task interface type.

20.a/3 **Proof:** Synchronized, protected, and task interfaces are all considered limited interfaces, see 3.9.4.

Incompatibilities With Ada 95

20.b/3 {*AI95-00240-01*} {*AI05-0248-1*} **Amendment Correction:** The wording was changed from "user-specified" to "available" read and write attributes. (This was then further changed, see below.) This means that an access type with the attributes specified in the private part would originally have been sufficient to allow the access type to be used in a remote type, but that is no longer allowed. Similarly, the attributes of a remote type that has access components have to be specified in the visible part. These changes were made so that the rules were consistent with the rules introduced for the Corrigendum for stream attributes; moreover, legality should not depend on the contents of the private part.

Extensions to Ada 95

20.c/3 {*AI95-00366-01*} {*AI05-0005-1*} Remote types that cannot be streamed (that is, have no available stream attributes) do not require the specification of stream attributes. This is necessary so that most extensions of Limited_Controlled do not need stream attributes defined (otherwise there would be a significant incompatibility, as Limited_Controlled would need stream attributes, and then all extensions of it also would need stream attributes).

Wording Changes from Ada 95

20.d/2 {*8652/0081*} {*AI95-00004-01*} **Corrigendum:** Added missing wording so that a type derived from a remote access type is also a remote access type.

20.e/2 {*8652/0083*} {*AI95-00047-01*} **Corrigendum:** Clarified that user-defined Read and Write attributes are required for the primitive subprograms corresponding to a remote access-to-class-wide type.

20.f/2 {*8652/0082*} {*AI95-00164-01*} **Corrigendum:** Added missing wording so that a remote access type can designate an appropriate private extension.

20.g/2 {*AI95-00366-01*} Changed the wording to use the newly defined term *type that supports external streaming*, so that various issues with access types in pure units and implicitly declared attributes for type extensions are properly handled.

20.h/2 {*AI95-00366-01*} Defined Storage_Size to be 0 for remote access-to-class-wide types, rather than having it undefined. This eliminates issues with pure units requiring a defined storage size.

20.i/2 {*AI95-00431-01*} Corrected the wording so that a value of a local access-to-subprogram type cannot be converted to a remote access-to-subprogram type, as intended (and required by the ACATS).

Incompatibilities With Ada 2005

20.j/5 {*AI05-0101-1*} {*AI12-0005-1*} {*AI12-0005-1*} **Correction:** Added rules about the returning of remote access-to-class-wide types; this had been missed in the past. While programs that returned unstreamable types from RCI functions

were legal, it is not clear what they could have done (as the results could not be marshalled). Similarly, RCI functions that return remote controlling access types could try to save those values, but it is unlikely that a compiler would know how to do that usefully. Thus, it seems unlikely that any real programs will be impacted by these changes.

Extensions to Ada 2005

{*AI05-0060-1*} **Correction:** Clarified that anonymous access types are never remote access types (and can be used in remote types units subject to the normal restrictions). Added wording to allow limited class-wide interfaces to be designated by remote access types. 20.k/3

{*AI05-0206-1*} Added wording to allow private withs of preelaborated normal units in the specification of a remote types unit. 20.l/3

{*AI05-0243-1*} {*AI12-0417-1*} Remote_Types is now a categorization aspect, so it can be specified by an aspect_specification 20.m/5

Wording Changes from Ada 2012

{*AI12-0034-1*} **Corrigendum:** Clarified that dispatching remote stream attribute calls are prohibited. We don't document this as an incompatibility, as the stream parameter cannot be marshalled for a remote call (it doesn't have external streaming), so it's impossible that any working program depends on this functionality. 20.n/4

{*AI12-0076-1*} **Corrigendum:** Explicitly stated that modifying a visible constant in a remote types package is erroneous. We don't document this as inconsistent as implementations certainly can still do whatever they were previously doing (no change is required); moreover, this case (and many more) were erroneous in Ada 2005 and before, so we're just restoring the previous semantics. 20.o/4

{*AI12-0085-1*} **Corrigendum:** Clarified that specifying the Storage_Pool or Storage_Size aspect for an access-to-class-wide type is not allowed. The intent is clear, and no implementation has ever allowed specifying the aspects (the attributes already cannot be specified), so we don't document this as an incompatibility. 20.p/4

{*AI12-0283-1*} Added a rule to ensure that potentially blocking remote calls are not considered nonblocking. 20.q/5

{*AI12-0417-1*} The pragma Remote_Types is now obsolescent. 20.r/5

E.2.3 Remote Call Interface Library Units

[A remote call interface library unit can be used as an interface for remote procedure calls (RPCs) (or remote function calls) between active partitions.] 1

Language Design Principles

The restrictions governing a remote call interface library unit are intended to ensure that the values of the actual parameters in a remote call can be meaningfully sent between two active partitions. 1.a

Paragraphs 2 through 6 were moved to Annex J, "Obsolescent Features".

Legality Rules

{*8652/0078*} {*AI95-00048-01*} {*AI05-0243-1*} {*AI12-0417-1*} When the library unit aspect (see 13.1.1) Remote_Call_Interface of a library unit is True, the library unit is a *remote call interface (RCI)*. A subprogram declared in the visible part of such a library unit, or declared by such a library unit, is called a *remote subprogram*. 7/5

Aspect Description for Remote_Call_Interface: Subprograms in a given package may be used in remote procedure calls. 7.a/3

{*AI05-0206-1*} {*AI05-0243-1*} The declaration of an RCI library unit shall be preelaborable (see 10.2.1), and shall depend semantically only upon declared pure library_items, shared passive library units, remote types library units, other remote call interface library units, or preelaborated normal library units that are mentioned only in private with clauses. 8/3

Ramification: {*AI05-0243-1*} We say declared pure library_item here, so that (all) limited views are allowed; those are not library units, but they are declared pure library_items. 8.a/3

{*8652/0078*} {*AI95-00048-01*} In addition, the following restrictions apply to an RCI library unit: 9/1

10/1 • {*8652/0078*} {*AI95-00048-01*} its visible part shall not contain the declaration of a variable;

10.a/1 **Reason:** {*8652/0078*} {*AI95-00048-01*} Remote call interface units do not provide remote data access. A shared passive package has to be used for that.

11/1 • {*8652/0078*} {*AI95-00048-01*} its visible part shall not contain the declaration of a limited type;

11.a/2 **Reason:** {*AI95-00240-01*} {*AI95-00366-01*} We disallow the declaration of task and protected types, since calling an entry or a protected subprogram implicitly passes an object of a limited type (the target task or protected object). We disallow other limited types since we require that such types have available Read and Write attributes, but we certainly don't want the Read and Write attributes themselves to involve remote calls (thereby defeating their purpose of marshalling the value for remote calls).

12/1 • {*8652/0078*} {*AI95-00048-01*} its visible part shall not contain a nested generic_declaration;

12.a **Reason:** This is disallowed because the body of the nested generic would presumably have access to data inside the body of the RCI package, and if instantiated in a different partition, remote data access might result, which is not supported.

13/3 • {*8652/0078*} {*AI95-00048-01*} {*AI05-0229-1*} it shall not be, nor shall its visible part contain, the declaration of a subprogram for which aspect Inline is True;

13.1/5 • {*AI12-0283-1*} it shall not be, nor shall its visible part contain, the declaration of a subprogram that is nonblocking (see 9.5);

13.a/5 **Reason:** All such subprograms are remote subprograms, and all calls on remote subprograms are considered potentially blocking, so they cannot statically be allowed in nonblocking code.

13.b/5 **Ramification:** The type declaration of a remote subprogram is illegal if the Nonblocking aspect is True, either implicitly by inheritance or by explicit specification.

14/3 • {*8652/0078*} {*AI95-00048-01*} {*AI95-00240-01*} {*AI95-00366-01*} {*AI05-0101-1*} it shall not be, nor shall its visible part contain, a subprogram (or access-to-subprogram) declaration whose profile has a parameter or result of a type that does not support external streaming (see 13.13.2);

14.a/3 **Ramification:** {*AI05-0101-1*} No anonymous access types support external streaming, so they are never allowed as parameters or results of RCI subprograms.

15 • any public child of the library unit shall be a remote call interface library unit.

15.a/5 **Reason:** {*AI12-0417-1*} No restrictions apply to the private part of an RCI package, and since a public child can “see” the private part of its parent, such a child must itself have a Remote_Call_Interface aspect, and be assigned to the same partition (see below).

15.b/5 **Discussion:** {*AI12-0417-1*} We considered making the public child of an RCI package implicitly RCI, but it seemed better to require an explicit aspect to avoid any confusion.

15.c Note that there is no need for a private child to be an RCI package, since it can only be seen from the body of its parent or its siblings, all of which are required to be in the same active partition.

15.1/5 {*AI12-0002-1*} Specification of a stream-oriented attribute is illegal in the specification of a remote call interface library unit. In addition to the places where Legality Rules normally apply (see 12.3), this rule applies also in the private part of an instance of a generic unit.

15.d/5 **Ramification:** This applies whether the stream-oriented attribute is specified with an attribute_definition_clause or with an aspect_specification.

15.e/5 **Reason:** Stream-oriented attributes are intended to be used locally (to marshall values), while subprograms in a remote call interface are intended to be used remotely. We resolve the conflict by banning the local use routines. The type should be included in a remote types package and imported into the remote call interface package.

16/5 {*AI05-0229-1*} {*AI12-0417-1*} All_Calls_Remote is a library unit aspect. If the All_Calls_Remote aspect of a library unit is True, the library unit shall be a remote call interface.

16.a/4 **Aspect Description for All_Calls_Remote:** All indirect or dispatching remote subprogram calls, and all direct remote subprogram calls, should use the Partition Communication Subsystem.

Post-Compilation Rules

A remote call interface library unit shall be assigned to at most one partition of a given program. A remote call interface library unit whose parent is also an RCI library unit shall be assigned only to the same partition as its parent. 17

Implementation Note: {*8652/0078*} {*AI95-00048-01*} The declaration of an RCI unit, with a calling-stub body, is automatically included in all active partitions with compilation units that depend on it. However the whole RCI library unit, including its (non-stub) body, will only be in one of the active partitions. 17.a/1

Notwithstanding the rule given in 10.2, a compilation unit in a given partition that semantically depends on the declaration of an RCI library unit, *needs* (in the sense of 10.2) only the declaration of the RCI library unit, not the body, to be included in that same partition. [Therefore, the body of an RCI library unit is included only in the partition to which the RCI library unit is explicitly assigned.] 18

Implementation Requirements

{*8652/0078*} {*AI95-00048-01*} {*AI05-0229-1*} {*AI12-0031-1*} If aspect All_Calls_Remote is True for a given RCI library unit, then the implementation shall route any of the following calls through the Partition Communication Subsystem (PCS); see E.5: 19/4

- {*AI12-0031-1*} A direct call to a subprogram of the RCI unit from outside the declarative region of the unit; 19.1/4
- {*AI12-0031-1*} An indirect call through a remote access-to-subprogram value that designates a subprogram of the RCI unit; 19.2/4
- {*AI12-0031-1*} A dispatching call with a controlling operand designated by a remote access-to-class-wide value whose tag identifies a type declared in the RCI unit. 19.3/4

Discussion: {*8652/0078*} {*AI95-00048-01*} {*AI05-0229-1*} {*AI12-0031-1*} {*AI12-0005-1*} When this aspect is False (or not used), it is presumed that most implementations will not make calls through the PCS if the call originates in the same partition as that of the RCI unit. When this aspect is True, all indirect or dispatching remote subprogram calls to the RCI unit, and all direct calls from outside the subsystem rooted at the RCI unit, are treated like calls from outside the partition, ensuring that the PCS is involved in all such calls (for debugging, redundancy, etc.). 19.a/5

Reason: {*AI12-0031-1*} {*AI12-0005-1*} There is no point in forcing local direct calls (including calls from children) to go through the PCS, since on the target system these calls are always local, and all the units are in the same active partition. 19.b/5

Implementation Permissions

{*AI05-0243-1*} {*AI12-0417-1*} {*AI12-0444-1*} An implementation may omit support for the Remote_Call_Interface aspect or the All_Calls_Remote aspect. [Explicit message-based communication between active partitions can be supported as an alternative to RPC.] 20/5

Ramification: {*AI12-0417-1*} Of course, it is pointless to support the All_Calls_Remote aspect if the Remote_Call_Interface aspect (or some approximate equivalent) is not supported. 20.a/5

Incompatibilities With Ada 95

{*AI95-00240-01*} {*AI05-0248-1*} **Amendment Correction:** The wording was changed from “user-specified” to “available” read and write attributes. (This was then further changed, see below.) This means that a type with the attributes specified in the private part would originally have been allowed as a formal parameter of an RCI subprogram, but that is no longer allowed. This change was made so that the rules were consistent with the rules introduced for the Corrigendum for stream attributes; moreover, legality should not depend on the contents of the private part. 20.b/3

Wording Changes from Ada 95

{*8652/0078*} {*AI95-00048-01*} **Corrigendum:** Changed the wording to allow a library subprogram to be a remote call interface unit. 20.c/2

20.d/2 {*AI95-00366-01*} Changed the wording to use the newly defined term *type that supports external streaming*, so that various issues with access types in pure units and implicitly declared attributes for type extensions are properly handled.

Incompatibilities With Ada 2005

20.e/3 {*AI05-0101-1*} **Correction:** Added a rule to ensure that function results are streamable; this was missing in previous versions of Ada. While programs that returned unstreamable types from RCI functions were legal, it is not clear what they could have done (as the results could not be marshalled). Thus, it seems unlikely that any real programs will be impacted by this change.

Extensions to Ada 2005

20.f/3 {*AI05-0206-1*} Added wording to allow private withs of preelaborated normal units in the specification of a remote call interface unit.

20.g/5 {*AI05-0229-1*} {*AI12-0417-1*} All_Calls_Remote is now a representation aspect, so it can be specified by an aspect_specification

20.h/5 {*AI05-0243-1*} {*AI12-0417-1*} Remote_Call_Interface is now a categorization aspect, so it can be specified by an aspect_specification

Inconsistencies With Ada 2012

20.i/4 {*AI12-0031-1*} **Corrigendum:** Redefined when indirect and dispatching remote calls have to be remote for a unit for which the aspect All_Calls_Remote is True. With the new rules, a local target called indirectly or via dispatching will be routed through the PCS, while that was not necessarily true in earlier Ada. If a program depended on local targets not being routed through the PCS even when All_Calls_Remote is used, then it might behave differently or fail in Ada 2012 as corrected with this refinement. This is highly unlikely as the PCS is going to be able to communicate with any partition of the program, including the local partition.

Incompatibilities With Ada 2012

20.j/5 {*AI12-0002-1*} **Correction:** Specifying user-defined stream-oriented attributes is now illegal in an RCI unit. If a program contains such attributes, they and their associated type will need to be moved to a remote types package (which is then imported into the RCI unit).

Wording Changes from Ada 2012

20.k/5 {*AI12-0283-1*} Added a rule to ensure that potentially blocking remote calls are not considered nonblocking.

20.l/5 {*AI12-0417-1*} The pragmas Remote_Call_Interface and All_Calls_Remote are now obsolescent.

E.3 Consistency of a Distributed System

1/3 {*AI05-0299-1*} [This subclause defines attributes and rules associated with verifying the consistency of a distributed program.]

Language Design Principles

1.a/3 {*AI05-0248-1*} The rules guarantee that remote call interface and shared passive library units are consistent among all partitions prior to the execution of a distributed program, so that the semantics of the distributed program are well defined.

Static Semantics

2/1 For a prefix P that statically denotes a program unit, the following attributes are defined:

3 P'Version Yields a value of the predefined type String that identifies the version of the compilation unit that contains the declaration of the program unit.

4 P'Body_Version
Yields a value of the predefined type String that identifies the version of the compilation unit that contains the body (but not any subunits) of the program unit.

5/1 {*8652/0084*} {*AI95-00104-01*} The *version* of a compilation unit changes whenever the compilation unit changes in a semantically significant way. This document does not define the exact meaning of

"semantically significant". It is unspecified whether there are other events (such as recompilation) that result in the version of a compilation unit changing.

This paragraph was deleted. 5.a/1

{*8652/0084*} {*AI95-00104-01*} If P is not a library unit, and P has no completion, then P'Body_Version returns the Body_Version of the innermost program unit enclosing the declaration of P. If P is a library unit, and P has no completion, then P'Body_Version returns a value that is different from Body_Version of any version of P that has a completion. 5.1/1

Bounded (Run-Time) Errors

In a distributed program, a library unit is *consistent* if the same version of its declaration is used throughout. It is a bounded error to elaborate a partition of a distributed program that contains a compilation unit that depends on a different version of the declaration of a shared passive or RCI library unit than that included in the partition to which the shared passive or RCI library unit was assigned. As a result of this error, Program_Error can be raised in one or both partitions during elaboration; in any case, the partitions become inaccessible to one another. 6

Ramification: Because a version changes if anything on which it depends undergoes a version change, requiring consistency for shared passive and remote call interface library units is sufficient to ensure consistency for the declared pure and remote types library units that define the types used for the objects and parameters through which interpartition communication takes place. 6.a

Note that we do not require matching Body_Versions; it is irrelevant for shared passive and remote call interface packages, since only one copy of their body exists in a distributed program (in the absence of implicit replication), and we allow the bodies to differ for declared pure and remote types packages from partition to partition, presuming that the differences are due to required error corrections that took place during the execution of a long-running distributed program. The Body_Version attribute provides a means for performing stricter consistency checks. 6.b

Wording Changes from Ada 95

{*8652/0084*} {*AI95-00104-01*} **Corrigendum:** Clarified the meaning of 'Version and 'Body_Version. 6.c/2

E.4 Remote Subprogram Calls

{*AI12-0359-1*} A *remote subprogram call* is a subprogram call that invokes the execution of a subprogram in another (active) partition. The partition that originates the remote subprogram call is the *calling partition*, and the partition that executes the corresponding subprogram body is the *called partition*. Some remote procedure calls are allowed to return prior to the completion of subprogram execution. These are called *asynchronous remote procedure calls*. 1/5

Discussion: {*AI12-0359-1*} Remote subprogram calls are always between active partitions; a passive partition has no execution resources of its own and thus cannot execute anything, while a remote subprogram call is always executed by the called partition. 1.a/5

There are three different ways of performing a remote subprogram call: 2

- As a direct call on a (remote) subprogram explicitly declared in a remote call interface; 3
- As an indirect call through a value of a remote access-to-subprogram type; 4
- As a dispatching call with a controlling operand designated by a value of a remote access-to-class-wide type. 5

The first way of calling corresponds to a *static* binding between the calling and the called partition. The latter two ways correspond to a *dynamic* binding between the calling and the called partition. 6

{*AI05-0101-1*} Remote types library units (see E.2.2) and remote call interface library units (see E.2.3) define the remote subprograms or remote access types used for remote subprogram calls. 7/3

Language Design Principles

7.a Remote subprogram calls are standardized since the RPC paradigm is widely-used, and establishing an interface to it in the annex will increase the portability and reusability of distributed programs.

Legality Rules

8 In a dispatching call with two or more controlling operands, if one controlling operand is designated by a value of a remote access-to-class-wide type, then all shall be.

8.1/5 {*AI12-0283-1*} A nonblocking program unit shall not contain, other than within nested units with Nonblocking specified as statically False, a dispatching call with a controlling operand designated by a value of a remote access-to-class-wide type.

8.a/5 **Reason:** Such a dispatching call is a potentially blocking call (see below) even if the called subprogram is nonblocking, so we must not assert that no blocking is possible.

8.b/5 **Ramification:** The calls is illegal if the Nonblocking aspect of the containing unit is True, either implicitly by inheritance or by explicit specification.

Dynamic Semantics

9 For the execution of a remote subprogram call, subprogram parameters (and later the results, if any) are passed using a stream-oriented representation (see 13.13.1) [which is suitable for transmission between partitions]. This action is called *marshalling*. *Unmarshalling* is the reverse action of reconstructing the parameters or results from the stream-oriented representation. [Marshalling is performed initially as part of the remote subprogram call in the calling partition; unmarshalling is done in the called partition. After the remote subprogram completes, marshalling is performed in the called partition, and finally unmarshalling is done in the calling partition.]

10 A *calling stub* is the sequence of code that replaces the subprogram body of a remotely called subprogram in the calling partition. A *receiving stub* is the sequence of code (the “wrapper”) that receives a remote subprogram call on the called partition and invokes the appropriate subprogram body.

10.a **Discussion:** The use of the term *stub* in this annex should not be confused with body_stub as defined in 10.1.3. The term *stub* is used here because it is a commonly understood term when talking about the RPC paradigm.

11 Remote subprogram calls are executed at most once, that is, if the subprogram call returns normally, then the called subprogram's body was executed exactly once.

12 The task executing a remote subprogram call blocks until the subprogram in the called partition returns, unless the call is asynchronous. For an asynchronous remote procedure call, the calling task can become ready before the procedure in the called partition returns.

13 If a construct containing a remote call is aborted, the remote subprogram call is *cancelled*. Whether the execution of the remote subprogram is immediately aborted as a result of the cancellation is implementation defined.

13.a **Implementation defined:** Whether the execution of the remote subprogram is immediately aborted as a result of cancellation.

14 If a remote subprogram call is received by a called partition before the partition has completed its elaboration, the call is kept pending until the called partition completes its elaboration (unless the call is cancelled by the calling partition prior to that).

15 If an exception is propagated by a remotely called subprogram, and the call is not an asynchronous call, the corresponding exception is reraised at the point of the remote subprogram call. For an asynchronous call, if the remote procedure call returns prior to the completion of the remotely called subprogram, any exception is lost.

The exception Communication_Error (see E.5) is raised if a remote call cannot be completed due to difficulties in communicating with the called partition. 16

{*AI12-0183-1*} All forms of remote subprogram calls are potentially blocking operations (see 9.5). 17/5

Reason: Asynchronous remote procedure calls are potentially blocking since the implementation may require waiting for the availability of shared resources to initiate the remote call. 17.a

{*8652/0085*} {*AI95-00215-01*} In a remote subprogram call with a formal parameter of a class-wide type, a check is made that the tag of the actual parameter identifies a tagged type declared in a declared-pure or shared passive library unit, or in the visible part of a remote types or remote call interface library unit. Program_Error is raised if this check fails. In a remote function call which returns a class-wide type, the same check is made on the function result. 18/1

Discussion: {*8652/0085*} {*AI95-00215-01*} This check makes certain that the specific type passed or returned in an RPC satisfies the rules for a "communicable" type. Normally this is guaranteed by the compile-time restrictions on remote call interfaces. However, with class-wide types, it is possible to pass an object whose tag identifies a type declared outside the "safe" packages. 18.a/1

This is considered an accessibility_check since only the types declared in "safe" packages are considered truly "global" (cross-partition). Other types are local to a single partition. This is analogous to the "accessibility" of global vs. local declarations in a single-partition program. 18.b

This rule replaces a rule from an early version of Ada 9X which was given in the subclause on Remote Types Library Units (now E.2.2, “Remote Types Library Units”). That rule tried to prevent "bad" types from being sent by arranging for their tags to mismatch between partitions. However, that interfered with other uses of tags. The new rule allows tags to agree in all partitions, even for those types which are not "safe" to pass in an RPC. 18.c

In a dispatching call with two or more controlling operands that are designated by values of a remote access-to-class-wide type, a check is made [(in addition to the normal Tag_Check — see 11.5)] that all the remote access-to-class-wide values originated from Access attribute_references that were evaluated by tasks of the same active partition. Constraint_Error is raised if this check fails. 19

Implementation Note: When a remote access-to-class-wide value is created by an Access attribute_reference, the identity of the active partition that evaluated the attribute_reference should be recorded in the representation of the remote access value. 19.a

Implementation Requirements

The implementation of remote subprogram calls shall conform to the PCS interface as defined by the specification of the language-defined package System.RPC (see E.5). The calling stub shall use the Do_RPC procedure unless the remote procedure call is asynchronous in which case Do_APC shall be used. On the receiving side, the corresponding receiving stub shall be invoked by the RPC-receiver. 20

Implementation Note: One possible implementation model is as follows: 20.a

The code for calls to subprograms declared in an RCI package is generated normally, that is, the call-site is the same as for a local subprogram call. The code for the remotely callable subprogram bodies is also generated normally. Subprogram's prologue and epilogue are the same as for a local call. 20.b

When compiling the specification of an RCI package, the compiler generates calling stubs for each visible subprogram. Similarly, when compiling the body of an RCI package, the compiler generates receiving stubs for each visible subprogram together with the appropriate tables to allow the RPC-receiver to locate the correct receiving stub. 20.c

For the statically bound remote calls, the identity of the remote partition is statically determined (it is resolved at configuration/link time). 20.d

The calling stub operates as follows: 20.e

- It allocates (or reuses) a stream of Params_Stream_Type of Initial_Size, and initializes it by repeatedly calling Write operations, first to identify which remote subprogram in the receiving partition is being called, and then to pass the incoming value of each of the **in** and **in out** parameters of the call. 20.f
- {*AI05-0229-1*} It allocates (or reuses) a stream for the Result, unless an aspect Asynchronous is specified as True for the procedure. 20.g/3
- {*AI05-0229-1*} It calls Do_RPC unless an aspect Asynchronous is specified as True for the procedure in which case it calls Do_APC. An access value designating the message stream allocated and initialized above 20.h/3

is passed as the Params parameter. An access value designating the Result stream is passed as the Result parameter.

20.i/3 • {*AI05-0229-1*} If the aspect Asynchronous is not specified for the procedure, Do_RPC blocks until a reply message arrives, and then returns to the calling stub. The stub returns after extracting from the Result stream, using Read operations, the **in out** and **out** parameters or the function result. If the reply message indicates that the execution of the remote subprogram propagated an exception, the exception is propagated from Do_RPC to the calling stub, and thence to the point of the original remote subprogram call. If Do_RPC detects that communication with the remote partition has failed, it propagates Communication_Error.

20.j On the receiving side, the RPC-receiver procedure operates as follows:

20.k • It is called from the PCS when a remote-subprogram-call message is received. The call originates in some remote call receiver task executed and managed in the context of the PCS.

20.l • It extracts information from the stream to identify the appropriate receiving stub.

20.m • The receiving stub extracts the **in** and **in out** parameters using Read from the stream designated by the Params parameter.

20.n • The receiving stub calls the actual subprogram body and, upon completion of the subprogram, uses Write to insert the results into the stream pointed to by the Result parameter. The receiving stub returns to the RPC-receiver procedure which in turn returns to the PCS. If the actual subprogram body propagates an exception, it is propagated by the RPC-receiver to the PCS, which handles the exception, and indicates in the reply message that the execution of the subprogram body propagated an exception. The exception occurrence can be represented in the reply message using the Write attribute of Ada.Exceptions.Exception_Occurrence.

20.o For remote access-to-subprogram types:

20.p A value of a remote access-to-subprogram type can be represented by the following components: a reference to the remote partition, an index to the package containing the remote subprogram, and an index to the subprogram within the package. The values of these components are determined at run time when the remote access value is created. These three components serve the same purpose when calling Do_APC/RPC, as in the statically bound remote calls; the only difference is that they are evaluated dynamically.

20.q For remote access-to-class-wide types:

20.r For each remote access-to-class-wide type, a calling stub is generated for each dispatching operation of the designated type. In addition, receiving stubs are generated to perform the remote dispatching operations in the called partition. The appropriate subprogram_body is determined as for a local dispatching call once the receiving stub has been reached.

20.s A value of a remote access-to-class-wide type can be represented with the following components: a reference to the remote partition, an index to a table (created one per each such access type) containing addresses of all the dispatching operations of the designated type, and an access value designating the actual remote object.

20.t Alternatively, a remote access-to-class-wide value can be represented as a normal access value, pointing to a "stub" object which in turn contains the information mentioned above. A call on any dispatching operation of such a stub object does the remote call, if necessary, using the information in the stub object to locate the target partition, etc. This approach has the advantage that less special-casing is required in the compiler. All access values can remain just a simple address.

20.u For a call to Do_RPC or Do_APC: The partition ID of all controlling operands are checked for equality (a Constraint_Error is raised if this check fails). The partition ID value is used for the Partition parameter. An index into the *tagged-type-descriptor* is created. This index points to the receiving stub of the class-wide operation. This index and the index to the table (described above) are written to the stream. Then, the actual parameters are marshalled into the message stream. For a controlling operand, only the access value designating the remote object is required (the other two components are already present in the other parameters).

20.v On the called partition (after the RPC-receiver has transferred control to the appropriate receiving stub) the parameters are first unmarshalled. Then, the tags of the controlling operands (obtained by dereferencing the pointer to the object) are checked for equality. If the check fails Constraint_Error is raised and propagated back to the calling partition, unless it is a result of an asynchronous call. Finally, a dispatching call to the specific subprogram (based on the controlling object's tag) is made. Note that since this subprogram is not in an RCI package, no specific stub is generated for it, it is called normally from the *dispatching stub*.

20.1/1 {*8652/0086*} {*AI95-00159-01*} With respect to shared variables in shared passive library units, the execution of the corresponding subprogram body of a synchronous remote procedure call is considered to be part of the execution of the calling task. The execution of the corresponding subprogram body of an asynchronous remote procedure call proceeds in parallel with the calling task and does not signal the next action of the calling task (see 9.10).

NOTE 1 A given active partition can both make and receive remote subprogram calls. Thus, an active partition can act as both a client and a server. 21

NOTE 2 If a given exception is propagated by a remote subprogram call, but the exception does not exist in the calling partition, the exception can be handled by an **others** choice or be propagated to and handled by a third partition. 22

Discussion: This situation can happen in a case of dynamically nested remote subprogram calls, where an intermediate call executes in a partition that does not include the library unit that defines the exception. 22.a

Wording Changes from Ada 95

{*8652/0086*} {*AI95-00159-01*} **Corrigendum:** Added rules so that tasks can safely access shared passive objects. 22.b/2

{*8652/0085*} {*AI95-00215-01*} **Corrigendum:** Clarified that the check on class-wide types also applies to values returned from remote subprogram call functions. 22.c/2

Wording Changes from Ada 2005

{*AI05-0101-1*} **Correction:** Corrected the text to note that remote access types can be defined in remote types units. 22.d/3

Wording Changes from Ada 2012

{*AI12-0283-1*} Added a rule to ensure that potentially blocking remote calls are not considered nonblocking. 22.e/5

{*AI12-0359-1*} Clarified that remote subprogram calls are always to active partitions. 22.f/5

E.4.1 Asynchronous Remote Calls

{*AI05-0229-1*} [This subclause introduces the aspect Asynchronous which can be specified to allow a remote subprogram call to return prior to completion of the execution of the corresponding remote subprogram body.] 1/3

Paragraphs 2 through 7 were deleted.

Static Semantics

{*AI05-0229-1*} For a remote procedure, the following language-defined representation aspect may be specified: 8/3

Asynchronous 8.1/3

The type of aspect Asynchronous is Boolean. If directly specified, the aspect_definition shall be a static expression. If not specified, the aspect is False.

Aspect Description for Asynchronous: Remote procedure calls are asynchronous; the caller continues without waiting for the call to return. 8.a/3

{*AI05-0229-1*} For a remote access type, the following language-defined representation aspect may be specified: 8.2/3

Asynchronous 8.3/3

The type of aspect Asynchronous is Boolean. If directly specified, the aspect_definition shall be a static expression. If not specified (including by inheritance), the aspect is False.

Legality Rules

{*AI05-0229-1*} If aspect Asynchronous is specified for a remote procedure, the formal parameters of the procedure shall all be of mode **in**. 8.4/3

{*AI05-0229-1*} If aspect Asynchronous is specified for a remote access type, the type shall be a remote access-to-class-wide type, or the type shall be a remote access-to-procedure type with the formal parameters of the designated profile of the type all of mode **in**. 8.5/3

Dynamic Semantics

9/3 {*AI05-0229-1*} A remote call is *asynchronous* if it is a call to a procedure, or a call through a value of an access-to-procedure type, for which aspect Asynchronous is True. In addition, if aspect Asynchronous is True for a remote access-to-class-wide type, then a dispatching call on a procedure with a controlling operand designated by a value of the type is asynchronous if the formal parameters of the procedure are all of mode **in**.

Implementation Requirements

10 Asynchronous remote procedure calls shall be implemented such that the corresponding body executes at most once as a result of the call.

10.a **To be honest:** It is not clear that this rule can be tested or even defined formally.

Extensions to Ada 2005

10.b/3 {*AI05-0229-1*} Aspect Asynchronous is new; pragma Asynchronous is now obsolescent.

E.4.2 Example of Use of a Remote Access-to-Class-Wide Type

Examples

1 *Example of using a remote access-to-class-wide type to achieve dynamic binding across active partitions:*

2/5
```
{AI12-0414-1} package Tapes
   with Pure is
   type Tape is abstract tagged limited private;
   -- Primitive dispatching operations where
   -- Tape is controlling operand
   procedure Copy (From, To : access Tape;
                   Num_Recs : in Natural) is abstract;
   procedure Rewind (T : access Tape) is abstract;
   -- More operations
private
   type Tape is ...
end Tapes;
```

3/5
```
{AI12-0414-1} with Tapes;
package Name_Server
   with Remote_Call_Interface is
   -- Dynamic binding to remote operations is achieved
   -- using the access-to-limited-class-wide type Tape_Ptr
   type Tape_Ptr is access all Tapes.Tape'Class;
   -- The following statically bound remote operations
   -- allow for a name-server capability in this example
   function  Find     (Name : String) return Tape_Ptr;
   procedure Register (Name : in String; T : in Tape_Ptr);
   procedure Remove   (T : in Tape_Ptr);
   -- More operations
end Name_Server;
```

4
```
package Tape_Driver is
  -- Declarations are not shown, they are irrelevant here
end Tape_Driver;
```

```
{AI12-0347-1} with Tapes, Name_Server;                                    5/5
package body Tape_Driver is
   type New_Tape is new Tapes.Tape with ...
   overriding
   procedure Rewind (T : access New_Tape);
   overriding
   procedure Copy
     (From, To : access New_Tape; Num_Recs: in Natural) is
   begin
      . . .
   end Copy;
   procedure Rewind (T : access New_Tape) is
   begin
      . . .
   end Rewind;
   -- Objects remotely accessible through use
   -- of Name_Server operations
   Tape1, Tape2 : aliased New_Tape;
begin
   Name_Server.Register ("NINE-TRACK",  Tape1'Access);
   Name_Server.Register ("SEVEN-TRACK", Tape2'Access);
end Tape_Driver;
```

```
with Tapes, Name_Server;                                                  6
-- Tape_Driver is not needed and thus not mentioned in the with_clause
procedure Tape_Client is
   T1, T2 : Name_Server.Tape_Ptr;
begin
   T1 := Name_Server.Find ("NINE-TRACK");
   T2 := Name_Server.Find ("SEVEN-TRACK");
   Tapes.Rewind (T1);
   Tapes.Rewind (T2);
   Tapes.Copy (T1, T2, 3);
end Tape_Client;
```

{*AI12-0452-1*} *Discussion of the example*: 7/5

Discussion: The example does not show the case where tapes are removed from or added to the system. In the former case, an appropriate exception needs to be defined to instruct the client to use another tape. In the latter, the Name_Server should have a query function visible to the clients to inform them about the availability of the tapes in the system. 7.a

This paragraph was deleted. 8/1

- The package Tapes provides the necessary declarations of the type and its primitive operations. 9
- Name_Server is a remote call interface package and is elaborated in a separate active partition to provide the necessary naming services (such as Register and Find) to the entire distributed program through remote subprogram calls. 10
- Tape_Driver is a normal package that is elaborated in a partition configured on the processing node that is connected to the tape device(s). The abstract operations are overridden to support the locally declared tape devices (Tape1, Tape2). The package is not visible to its clients, but it exports the tape devices (as remote objects) through the services of the Name_Server. This allows for tape devices to be dynamically added, removed or replaced without requiring the modification of the clients' code. 11
- {*AI12-0442-1*} The Tape_Client procedure references only declarations in the Tapes and Name_Server packages. Before using a tape for the first time, it will query the Name_Server for a system-wide identity for that tape. From then on, it can use that identity to access the tape device. 12/5
- Values of remote access type Tape_Ptr include the necessary information to complete the remote dispatching operations that result from dereferencing the controlling operands T1 and T2. 13

E.5 Partition Communication Subsystem

1/2 {*AI95-00273-01*} [The *Partition Communication Subsystem* (PCS) provides facilities for supporting communication between the active partitions of a distributed program. The package System.RPC is a language-defined interface to the PCS.]

1.a **Reason:** The prefix RPC is used rather than RSC because the term remote procedure call and its acronym are more familiar.

Static Semantics

2 The following language-defined library package exists:

3/5
```
{AI12-0241-1} {AI12-0302-1} with Ada.Streams; -- see 13.13.1
package System.RPC
   with Nonblocking => False, Global => in out synchronized is
```

4
```
   type Partition_Id is range 0 .. implementation-defined;
```

5
```
   Communication_Error : exception;
```

6
```
   type Params_Stream_Type (
      Initial_Size : Ada.Streams.Stream_Element_Count) is new
      Ada.Streams.Root_Stream_Type with private;
```

7
```
   procedure Read(
      Stream : in out Params_Stream_Type;
      Item : out Ada.Streams.Stream_Element_Array;
      Last : out Ada.Streams.Stream_Element_Offset);
```

8
```
   procedure Write(
      Stream : in out Params_Stream_Type;
      Item : in Ada.Streams.Stream_Element_Array);
```

9
```
   -- Synchronous call
   procedure Do_RPC(
      Partition  : in Partition_Id;
      Params     : access Params_Stream_Type;
      Result     : access Params_Stream_Type);
```

10
```
   -- Asynchronous call
   procedure Do_APC(
      Partition  : in Partition_Id;
      Params     : access Params_Stream_Type);
```

11
```
   -- The handler for incoming RPCs
   type RPC_Receiver is access procedure(
      Params     : access Params_Stream_Type;
      Result     : access Params_Stream_Type);
```

12
```
   procedure Establish_RPC_Receiver(
      Partition : in Partition_Id;
      Receiver  : in RPC_Receiver);
```

13
```
private
   ... -- not specified by the language
end System.RPC;
```

14 A value of the type Partition_Id is used to identify a partition.

14.a/2 **Implementation defined:** The range of type System.RPC.Partition_Id.

15 An object of the type Params_Stream_Type is used for identifying the particular remote subprogram that is being called, as well as marshalling and unmarshalling the parameters or result of a remote subprogram call, as part of sending them between partitions.

16 [The Read and Write procedures override the corresponding abstract operations for the type Params_Stream_Type.]

Dynamic Semantics

The Do_RPC and Do_APC procedures send a message to the active partition identified by the Partition parameter. 17

Implementation Note: It is assumed that the RPC interface is above the message-passing layer of the network protocol stack and is implemented in terms of it. 17.a

After sending the message, Do_RPC blocks the calling task until a reply message comes back from the called partition or some error is detected by the underlying communication system in which case Communication_Error is raised at the point of the call to Do_RPC. 18

Reason: Only one exception is defined in System.RPC, although many sources of errors might exist. This is so because it is not always possible to distinguish among these errors. In particular, it is often impossible to tell the difference between a failing communication link and a failing processing node. Additional information might be associated with a particular Exception_Occurrence for a Communication_Error. 18.a

Do_APC operates in the same way as Do_RPC except that it is allowed to return immediately after sending the message. 19

Upon normal return, the stream designated by the Result parameter of Do_RPC contains the reply message. 20

The procedure System.RPC.Establish_RPC_Receiver is called once, immediately after elaborating the library units of an active partition (that is, right after the *elaboration of the partition*) if the partition includes an RCI library unit, but prior to invoking the main subprogram, if any. The Partition parameter is the Partition_Id of the active partition being elaborated. The Receiver parameter designates an implementation-provided procedure called the *RPC-receiver* which will handle all RPCs received by the partition from the PCS. Establish_RPC_Receiver saves a reference to the RPC-receiver; when a message is received at the called partition, the RPC-receiver is called with the Params stream containing the message. When the RPC-receiver returns, the contents of the stream designated by Result is placed in a message and sent back to the calling partition. 21

Implementation Note: It is defined by the PCS implementation whether one or more threads of control should be available to process incoming messages and to wait for their completion. 21.a

Implementation Note: At link-time, the linker provides the RPC-receiver and the necessary tables to support it. A call on Establish_RPC_Receiver is inserted just before the call on the main subprogram. 21.b

Reason: The interface between the PCS (the System.RPC package) and the RPC-receiver is defined to be dynamic in order to allow the elaboration sequence to notify the PCS that all packages have been elaborated and that it is safe to call the receiving stubs. It is not guaranteed that the PCS units will be the last to be elaborated, so some other indication that elaboration is complete is needed. 21.c

If a call on Do_RPC is aborted, a cancellation message is sent to the called partition, to request that the execution of the remotely called subprogram be aborted. 22

To be honest: The full effects of this message are dependent on the implementation of the PCS. 22.a

This paragraph was deleted.{*AI12-0241-1*} 23/5

Implementation Requirements

The implementation of the RPC-receiver shall be reentrant[, thereby allowing concurrent calls on it from the PCS to service concurrent remote subprogram calls into the partition]. 24

Reason: There seems no reason to allow the implementation of RPC-receiver to be nonreentrant, even though we don't require that every implementation of the PCS actually perform concurrent calls on the RPC-receiver. 24.a

{*8652/0087*} {*AI95-00082-01*} An implementation shall not restrict the replacement of the body of System.RPC. An implementation shall not restrict children of System.RPC. [The related implementation permissions in the introduction to Annex A do not apply.] 24.1/1

24.a.1/1 **Reason:** The point of System.RPC is to let the user tailor the communications mechanism without requiring changes to or other cooperation from the compiler. However, implementations can restrict the replacement of language-defined units. This requirement overrides that permission for System.RPC.

24.2/1 {*8652/0087*} {*AI95-00082-01*} If the implementation of System.RPC is provided by the user, an implementation shall support remote subprogram calls as specified.

24.b/2 **Discussion:** {*AI95-00273-01*} If the implementation takes advantage of the implementation permission to use a different specification for System.RPC, it still needs to use it for remote subprogram calls, and allow the user to replace the body of System.RPC. It just isn't guaranteed to be portable to do so in Ada 2005 - an advantage which was more theoretical than real anyway.

Documentation Requirements

25 The implementation of the PCS shall document whether the RPC-receiver is invoked from concurrent tasks. If there is an upper limit on the number of such tasks, this limit shall be documented as well, together with the mechanisms to configure it (if this is supported).

25.a/2 *This paragraph was deleted.*

25.a.1/2 **Documentation Requirement:** Whether the RPC-receiver is invoked from concurrent tasks, and if so, the number of such tasks.

Implementation Permissions

26 The PCS is allowed to contain implementation-defined interfaces for explicit message passing, broadcasting, etc. Similarly, it is allowed to provide additional interfaces to query the state of some remote partition (given its partition ID) or of the PCS itself, to set timeouts and retry parameters, to get more detailed error status, etc. These additional interfaces should be provided in child packages of System.RPC.

26.a **Implementation defined:** Implementation-defined interfaces in the PCS.

27/5 {*AI12-0444-1*} A body for the package System.RPC is not required to be supplied by the implementation.

27.a **Reason:** It is presumed that a body for the package System.RPC might be extremely environment specific. Therefore, we do not require that a body be provided by the (compiler) implementation. The user will have to write a body, or acquire one, appropriate for the target environment.

27.1/3 {*AI95-00273-01*} {*AI05-0299-1*} An alternative declaration is allowed for package System.RPC as long as it provides a set of operations that is substantially equivalent to the specification defined in this subclause.

27.b/2 **Reason:** Experience has proved that the definition of System.RPC given here is inadequate for interfacing to existing distribution mechanisms (such as CORBA), especially on heterogeneous systems. Rather than mandate a change in the mechanism (which would break existing systems), require implementations to support multiple mechanisms (which is impractical), or prevent the use of Annex E facilities with existing systems (which would be silly), we simply make this facility optional.

27.c/2 One of the purposes behind System.RPC was that knowledgeable users, rather than compiler vendors, could create this package tailored to their networks. Experience has shown that users get their RPC from vendors anyway; users have not taken advantage of the flexibility provided by this defined interface. Moreover, one could compare this defined interface to requiring Ada compilers to use a defined interface to implement tasking. No one thinks that the latter is a good idea, why should anyone believe that the former is?

27.d/3 {*AI05-0299-1*} Therefore, this subclause is made optional. We considered deleting the subclause outright, but we still require that users may replace the package (whatever its interface). Also, it still provides a useful guide to the implementation of this feature.

Implementation Advice

28 Whenever possible, the PCS on the called partition should allow for multiple tasks to call the RPC-receiver with different messages and should allow them to block until the corresponding subprogram body returns.

28.a/2 **Implementation Advice:** The PCS should allow for multiple tasks to call the RPC-receiver.

The Write operation on a stream of type Params_Stream_Type should raise Storage_Error if it runs out of space trying to write the Item into the stream. 29

Implementation Advice: The System.RPC.Write operation should raise Storage_Error if it runs out of space when writing an item. 29.a.1/2

Implementation Note: An implementation could also dynamically allocate more space as needed, only propagating Storage_Error if the allocator it calls raises Storage_Error. This storage could be managed through a controlled component of the stream object, to ensure that it is reclaimed when the stream object is finalized. 29.a

NOTE The package System.RPC is not designed for direct calls by user programs. It is instead designed for use in the implementation of remote subprograms calls, being called by the calling stubs generated for a remote call interface library unit to initiate a remote call, and in turn calling back to an RPC-receiver that dispatches to the receiving stubs generated for the body of a remote call interface, to handle a remote call received from elsewhere. 30

Incompatibilities With Ada 95

{*AI95-00273-01*} The specification of System.RPC can now be tailored for an implementation. If a program replaces the body of System.RPC with a user-defined body, it might not compile in a given implementation of Ada 2005 (if the specification of System.RPC has been changed). 30.a/2

Wording Changes from Ada 95

{*8652/0087*} {*AI95-00082-01*} **Corrigendum:** Clarified that the user can replace System.RPC. 30.b/2

Annex F
(normative)
Information Systems

This Annex provides a set of facilities relevant to Information Systems programming. These fall into several categories: 1

- an attribute definition clause specifying Machine_Radix for a decimal subtype; 2
- the package Decimal, which declares a set of constants defining the implementation's capacity for decimal types, and a generic procedure for decimal division; and 3
- {*AI95-00285-01*} the child packages Text_IO.Editing, Wide_Text_IO.Editing, and Wide_Wide_Text_IO.Editing, which support formatted and localized output of decimal data, based on "picture String" values. 4/2

{*AI95-00434-01*} {*AI12-0449-1*} Other relevant facilities can be found in: 3.5.9, "Fixed Point Types"; 3.5.10, "Operations of Fixed Point Types"; 4.6, "Type Conversions"; 13.3, "Operational and Representation Attributes"; A.10.9, "Input-Output for Real Types"; B.3, "Interfacing with C and C++"; B.4, "Interfacing with COBOL"; Annex G, "Numerics". 5/5

The character and string handling packages in Annex A, "Predefined Language Environment" are also relevant for Information Systems. 6

Implementation Advice

{*AI05-0229-1*} If COBOL (respectively, C) is widely supported in the target environment, implementations supporting the Information Systems Annex should provide the child package Interfaces.COBOL (respectively, Interfaces.C) specified in Annex B and should support a *convention*_identifier of COBOL (respectively, C) for the Convention aspect (see Annex B), thus allowing Ada programs to interface with programs written in that language. 7/3

Implementation Advice: If COBOL (respectively, C) is supported in the target environment, then interfacing to COBOL (respectively, C) should be supported as specified in Annex B. 7.a/2

Extensions to Ada 83

This Annex is new to Ada 95. 7.b

Wording Changes from Ada 95

{*AI95-00285-01*} Added a mention of Wide_Wide_Text_IO.Editing, part of the support for 32-bit characters. 7.c/2

F.1 Machine_Radix Attribute Definition Clause

Static Semantics

{*AI12-0272-1*} The representation attribute Machine_Radix may be specified for a decimal first subtype (see 3.5.9) via an attribute_definition_clause; the expression of such a clause shall be static, and its value shall be 2 or 10. A value of 2 implies a binary base range; a value of 10 implies a decimal base range. 1/5

Ramification: In the absence of a Machine_Radix clause, the choice of 2 versus 10 for S'Machine_Radix is not specified. 1.a

Aspect Description for Machine_Radix: Radix (2 or 10) that is used to represent a decimal fixed point type. 1.b/3

Implementation Advice

2 Packed decimal should be used as the internal representation for objects of subtype S when S'Machine_Radix = 10.

2.a/2 **Implementation Advice:** Packed decimal should be used as the internal representation for objects of subtype *S* when *S*'Machine_Radix = 10.

2.b/3 **Discussion:** {*AI05-0229-1*} The intent of a decimal Machine_Radix attribute definition clause is to allow the programmer to declare an Ada decimal data object whose representation matches a particular COBOL implementation's representation of packed decimal items. The Ada object may then be passed to an interfaced COBOL program that takes a packed decimal data item as a parameter, assuming that convention COBOL has been specified for the Ada object's type with an aspect Convention.

2.c Additionally, the Ada compiler may choose to generate arithmetic instructions that exploit the packed decimal representation.

Examples

3 *Example of Machine_Radix attribute definition clause:*

4
```
type Money is delta 0.01 digits 15;
for Money'Machine_Radix use 10;
```

Wording Changes from Ada 2012

4.a/5 {*AI12-0272-1*} Clarified that Machine_Radix is a representation aspect.

F.2 The Package Decimal

Static Semantics

1 The library package Decimal has the following declaration:

2/5
```
{AI12-0414-1} package Ada.Decimal
   with Pure is

3     Max_Scale : constant := implementation-defined;
      Min_Scale : constant := implementation-defined;

4     Min_Delta : constant := 10.0**(-Max_Scale);
      Max_Delta : constant := 10.0**(-Min_Scale);

5     Max_Decimal_Digits : constant := implementation-defined;

6/3 {AI05-0229-1}    generic
         type Dividend_Type  is delta <> digits <>;
         type Divisor_Type   is delta <> digits <>;
         type Quotient_Type  is delta <> digits <>;
         type Remainder_Type is delta <> digits <>;
      procedure Divide (Dividend  : in Dividend_Type;
                        Divisor   : in Divisor_Type;
                        Quotient  : out Quotient_Type;
                        Remainder : out Remainder_Type)
         with Convention => Intrinsic;

7  end Ada.Decimal;
```

7.a **Implementation defined:** The values of named numbers in the package Decimal.

8 Max_Scale is the largest N such that 10.0**(–N) is allowed as a decimal type's delta. Its type is *universal_integer*.

9 Min_Scale is the smallest N such that 10.0**(–N) is allowed as a decimal type's delta. Its type is *universal_integer*.

10 Min_Delta is the smallest value allowed for *delta* in a decimal_fixed_point_definition. Its type is *universal_real*.

Max_Delta is the largest value allowed for *delta* in a decimal_fixed_point_definition. Its type is *universal_real*. 11

Max_Decimal_Digits is the largest value allowed for *digits* in a decimal_fixed_point_definition. Its type is *universal_integer*. 12

Reason: The name is Max_Decimal_Digits versus Max_Digits, in order to avoid confusion with the named number System.Max_Digits relevant to floating point. 12.a

Static Semantics

The effect of Divide is as follows. The value of Quotient is Quotient_Type(Dividend/Divisor). The value of Remainder is Remainder_Type(Intermediate), where Intermediate is the difference between Dividend and the product of Divisor and Quotient; this result is computed exactly. 13

Implementation Requirements

Decimal.Max_Decimal_Digits shall be at least 18. 14

Decimal.Max_Scale shall be at least 18. 15

Decimal.Min_Scale shall be at most 0. 16

NOTE The effect of division yielding a quotient with control over rounding versus truncation is obtained by applying either the function attribute Quotient_Type'Round or the conversion Quotient_Type to the expression Dividend/Divisor. 17

F.3 Edited Output for Decimal Types

{*AI95-00285-01*} The child packages Text_IO.Editing, Wide_Text_IO.Editing, and Wide_Wide_Text_IO.Editing provide localizable formatted text output, known as *edited output*, for decimal types. An edited output string is a function of a numeric value, program-specifiable locale elements, and a format control value. The numeric value is of some decimal type. The locale elements are: 1/2

- the currency string; 2
- the digits group separator character; 3
- the radix mark character; and 4
- the fill character that replaces leading zeros of the numeric value. 5

{*AI95-00285-01*} For Text_IO.Editing the edited output and currency strings are of type String, and the locale characters are of type Character. For Wide_Text_IO.Editing their types are Wide_String and Wide_Character, respectively. For Wide_Wide_Text_IO.Editing their types are Wide_Wide_String and Wide_Wide_Character, respectively. 6/2

Each of the locale elements has a default value that can be replaced or explicitly overridden. 7

A format-control value is of the private type Picture; it determines the composition of the edited output string and controls the form and placement of the sign, the position of the locale elements and the decimal digits, the presence or absence of a radix mark, suppression of leading zeros, and insertion of particular character values. 8

A Picture object is composed from a String value, known as a *picture String*, that serves as a template for the edited output string, and a Boolean value that controls whether a string of all space characters is produced when the number's value is zero. A picture String comprises a sequence of one- or two-Character symbols, each serving as a placeholder for a character or string at a corresponding position in the edited output string. The picture String symbols fall into several categories based on their effect on the edited output string: 9

10

Decimal Digit:	'9'					
Radix Control:	'.'	'V'				
Sign Control:	'+'	'–'	'<'	'>'	"CR"	"DB"
Currency Control:	'$'	'#'				
Zero Suppression:	'Z'	'*'				
Simple Insertion:	'_'	'B'	'0'	'/'		

11 The entries are not case-sensitive. Mixed- or lower-case forms for "CR" and "DB", and lower-case forms for 'V', 'Z', and 'B', have the same effect as the upper-case symbols shown.

12 An occurrence of a '9' Character in the picture String represents a decimal digit position in the edited output string.

13 A radix control Character in the picture String indicates the position of the radix mark in the edited output string: an actual character position for '.', or an assumed position for 'V'.

14 A sign control Character in the picture String affects the form of the sign in the edited output string. The '<' and '>' Character values indicate parentheses for negative values. A Character '+', '–', or '<' appears either singly, signifying a fixed-position sign in the edited output, or repeated, signifying a floating-position sign that is preceded by zero or more space characters and that replaces a leading 0.

15 A currency control Character in the picture String indicates an occurrence of the currency string in the edited output string. The '$' Character represents the complete currency string; the '#' Character represents one character of the currency string. A '$' Character appears either singly, indicating a fixed-position currency string in the edited output, or repeated, indicating a floating-position currency string that occurs in place of a leading 0. A sequence of '#' Character values indicates either a fixed- or floating-position currency string, depending on context.

16 A zero suppression Character in the picture String allows a leading zero to be replaced by either the space character (for 'Z') or the fill character (for '*').

17 A simple insertion Character in the picture String represents, in general, either itself (if '/' or '0'), the space character (if 'B'), or the digits group separator character (if '_'). In some contexts it is treated as part of a floating sign, floating currency, or zero suppression string.

18/2 {*AI95-00434-01*} An example of a picture String is "<###Z_ZZ9.99>". If the currency string is "kr", the separator character is ',', and the radix mark is '.' then the edited output string values for the decimal values 32.10 and –5432.10 are "bbkrbbb32.10b" and "(bkr5,432.10)", respectively, where 'b' indicates the space character.

19/2 {*AI95-00285-01*} The generic packages Text_IO.Decimal_IO, Wide_Text_IO.Decimal_IO, and Wide_-Wide_Text_IO.Decimal_IO (see A.10.9, “Input-Output for Real Types”) provide text input and nonedited text output for decimal types.

20/2 NOTE {*AI95-00285-01*} A picture String is of type Standard.String, for all of Text_IO.Editing, Wide_Text_IO.Editing, and Wide_Wide_Text_IO.Editing.

Wording Changes from Ada 95

20.a/2 {*AI95-00285-01*} Added descriptions of Wide_Wide_Text_IO.Editing; see F.3.5.

F.3.1 Picture String Formation

1/3 {*AI05-0299-1*} A *well-formed picture String*, or simply *picture String*, is a String value that conforms to the syntactic rules, composition constraints, and character replication conventions specified in this subclause.

Dynamic Semantics

all_zero_suppression_aft_char ::= zero_suppression_char | context_sensitive_insertion

zero_suppression_char ::= Z | * 38

The following composition constraints apply to a picture String: 39

- A floating_LHS_sign does not have occurrences of different LHS_Sign Character values. 40
- If a picture String has '<' as fixed_LHS_sign, then it has '>' as RHS_sign. 41
- If a picture String has '<' in a floating_LHS_sign or in an all_sign_number, then it has an occurrence of '>'. 42
- {*8652/0088*} {*AI95-00153*} If a picture String has '+' or '–' as fixed_LHS_sign, in a floating_LHS_sign, or in an all_sign_number, then it has no RHS_sign or '>' character. 43/1
- An instance of all_sign_number does not have occurrences of different sign_char Character values. 44

45 • An instance of all_currency_number does not have occurrences of different currency_char Character values.

46 • An instance of all_zero_suppression_number does not have occurrences of different zero_-suppression_char Character values, except for possible case differences between 'Z' and 'z'.

47 A *replicable Character* is a Character that, by the above rules, can occur in two consecutive positions in a picture String.

48 A *Character replication* is a String

49 *char* & '(' & *spaces* & *count_string* & ')'

50 where *char* is a replicable Character, *spaces* is a String (possibly empty) comprising only space Character values, and *count_string* is a String of one or more decimal digit Character values. A Character replication in a picture String has the same effect as (and is said to be *equivalent to*) a String comprising *n* consecutive occurrences of *char*, where *n*=Integer'Value(*count_string*).

51 An *expanded picture String* is a picture String containing no Character replications.

51.a **Discussion:** Since 'B' is not allowed after a RHS sign, there is no need for a special rule to disallow "9.99DB(2)" as an abbreviation for "9.99DBB"

52 NOTE Although a sign to the left of the number can float, a sign to the right of the number is in a fixed position.

Wording Changes from Ada 95

52.a/2 {*8652/0088*} {*AI95-00153-01*} **Corrigendum:** The picture string rules for numbers were tightened.

F.3.2 Edited Output Generation

Dynamic Semantics

1 The contents of an edited output string are based on:

2 • A value, Item, of some decimal type Num,

3 • An expanded picture String Pic_String,

4 • A Boolean value, Blank_When_Zero,

5 • A Currency string,

6 • A Fill character,

7 • A Separator character, and

8 • A Radix_Mark character.

9 The combination of a True value for Blank_When_Zero and a '*' character in Pic_String is inconsistent; no edited output string is defined.

9.a/2 **Reason:** {*AI95-00114-01*} Such a Pic_String is invalid, and any attempt to use such a string will raise Picture_Error.

10 A layout error is identified in the rules below if leading nonzero digits of Item, character values of the Currency string, or a negative sign would be truncated; in such cases no edited output string is defined.

11 The edited output string has lower bound 1 and upper bound N where N = Pic_String'Length + Currency_Length_Adjustment – Radix_Adjustment, and

12 • Currency_Length_Adjustment = Currency'Length – 1 if there is some occurrence of '$' in Pic_String, and 0 otherwise.

13 • Radix_Adjustment = 1 if there is an occurrence of 'V' or 'v' in Pic_Str, and 0 otherwise.

Let the magnitude of Item be expressed as a base-10 number $I_p \cdots I_1.F_1 \cdots F_q$, called the *displayed magnitude* of Item, where: 14

- q = Min(Max(Num'Scale, 0), n) where n is 0 if Pic_String has no radix and is otherwise the number of digit positions following radix in Pic_String, where a digit position corresponds to an occurrence of '9', a zero_suppression_char (for an all_zero_suppression_number), a currency_char (for an all_currency_number), or a sign_char (for an all_sign_number). 15
- I_p /= 0 if p>0. 16

If n < Num'Scale, then the above number is the result of rounding (away from 0 if exactly midway between values). 17

If Blank_When_Zero = True and the displayed magnitude of Item is zero, then the edited output string comprises all space character values. Otherwise, the picture String is treated as a sequence of instances of syntactic categories based on the rules in F.3.1, and the edited output string is the concatenation of string values derived from these categories according to the following mapping rules. 18

{*AI12-0451-1*} Table F.1 shows the mapping from a sign control symbol to a corresponding character or string in the edited output. In the columns showing the edited output, a lower-case 'b' represents the space character. If there is no sign control symbol but the value of Item is negative, a layout error occurs and no edited output string is produced. 19/5

Table F.1: Edited Output for Sign Control Symbols

Sign Control Symbol	Edited Output for Nonnegative Number	Edited Output for Negative Number
'+'	'+'	'–'
'–'	'b'	'–'
'<'	'b'	'('
'>'	'b'	')'
"CR"	"bb"	"CR"
"DB"	"bb"	"DB"

{*AI12-0451-1*} An instance of fixed_LHS_sign maps to a character as shown in Table F.1. 20/5

An instance of fixed_$_char maps to Currency. 21

An instance of direct_insertion maps to Separator if direct_insertion = '_', and to the direct_insertion Character otherwise. 22

An instance of number maps to a string *integer_part* & *radix_part* & *fraction_part* where: 23

- The string for *integer_part* is obtained as follows: 24
  1. Occurrences of '9' in fore_digits of number are replaced from right to left with the decimal digit character values for I_1, ..., I_p, respectively. 25
  2. Each occurrence of '9' in fore_digits to the left of the leftmost '9' replaced according to rule 1 is replaced with '0'. 26
  3. If p exceeds the number of occurrences of '9' in fore_digits of number, then the excess leftmost digits are eligible for use in the mapping of an instance of zero_suppression, 27

floating_LHS_sign, floating_$_currency, or floating_#_currency to the left of number; if there is no such instance, then a layout error occurs and no edited output string is produced.

- The *radix_part* is:
  - "" if number does not include a radix, if radix = 'V', or if radix = 'v'
  - Radix_Mark if number includes '.' as radix
- The string for *fraction_part* is obtained as follows:
  1. Occurrences of '9' in aft_digits of number are replaced from left to right with the decimal digit character values for F_1, ... F_q.
  2. Each occurrence of '9' in aft_digits to the right of the rightmost '9' replaced according to rule 1 is replaced by '0'.

An instance of zero_suppression maps to the string obtained as follows:

1. The rightmost 'Z', 'z', or '*' Character values are replaced with the excess digits (if any) from the *integer_part* of the mapping of the number to the right of the zero_suppression instance,
2. A context_sensitive_insertion Character is replaced as though it were a direct_insertion Character, if it occurs to the right of some 'Z', 'z', or '*' in zero_suppression that has been mapped to an excess digit,
3. Each Character to the left of the leftmost Character replaced according to rule 1 above is replaced by:
   - the space character if the zero suppression Character is 'Z' or 'z', or
   - the Fill character if the zero suppression Character is '*'.
4. A layout error occurs if some excess digits remain after all 'Z', 'z', and '*' Character values in zero_suppression have been replaced via rule 1; no edited output string is produced.

{*AI12-0451-1*} An instance of RHS_sign maps to a character or string as shown in Table F.1.

An instance of floating_LHS_sign maps to the string obtained as follows.

1. Up to all but one of the rightmost LHS_Sign Character values are replaced by the excess digits (if any) from the *integer_part* of the mapping of the number to the right of the floating_LHS_sign instance.
2. {*AI12-0451-1*} The next Character to the left is replaced with the character given by the entry in Table F.1 corresponding to the LHS_Sign Character.
3. A context_sensitive_insertion Character is replaced as though it were a direct_insertion Character, if it occurs to the right of the leftmost LHS_Sign character replaced according to rule 1.
4. Any other Character is replaced by the space character.
5. A layout error occurs if some excess digits remain after replacement via rule 1; no edited output string is produced.

An instance of fixed_#_currency maps to the Currency string with n space character values concatenated on the left (if the instance does not follow a radix) or on the right (if the instance does follow a radix), where n is the difference between the length of the fixed_#_currency instance and Currency'Length. A layout error occurs if Currency'Length exceeds the length of the fixed_#_currency instance; no edited output string is produced.

An instance of floating_$_currency maps to the string obtained as follows:

1. Up to all but one of the rightmost '$' Character values are replaced with the excess digits (if any) from the *integer_part* of the mapping of the number to the right of the floating_$_currency instance. 50
2. The next Character to the left is replaced by the Currency string. 51
3. A context_sensitive_insertion Character is replaced as though it were a direct_insertion Character, if it occurs to the right of the leftmost '$' Character replaced via rule 1. 52
4. Each other Character is replaced by the space character. 53
5. A layout error occurs if some excess digits remain after replacement by rule 1; no edited output string is produced. 54

An instance of floating_#_currency maps to the string obtained as follows: 55

1. Up to all but one of the rightmost '#' Character values are replaced with the excess digits (if any) from the *integer_part* of the mapping of the number to the right of the floating_#_currency instance. 56
2. The substring whose last Character occurs at the position immediately preceding the leftmost Character replaced via rule 1, and whose length is Currency'Length, is replaced by the Currency string. 57
3. A context_sensitive_insertion Character is replaced as though it were a direct_insertion Character, if it occurs to the right of the leftmost '#' replaced via rule 1. 58
4. Any other Character is replaced by the space character. 59
5. A layout error occurs if some excess digits remain after replacement rule 1, or if there is no substring with the required length for replacement rule 2; no edited output string is produced. 60

An instance of all_zero_suppression_number maps to: 61

- a string of all spaces if the displayed magnitude of Item is zero, the zero_suppression_char is 'Z' or 'z', and the instance of all_zero_suppression_number does not have a radix at its last character position; 62
- a string containing the Fill character in each position except for the character (if any) corresponding to radix, if zero_suppression_char = '*' and the displayed magnitude of Item is zero; 63
- otherwise, the same result as if each zero_suppression_char in all_zero_suppression_aft were '9', interpreting the instance of all_zero_suppression_number as either zero_suppression number (if a radix and all_zero_suppression_aft are present), or as zero_suppression otherwise. 64

An instance of all_sign_number maps to: 65

- a string of all spaces if the displayed magnitude of Item is zero and the instance of all_sign_number does not have a radix at its last character position; 66
- otherwise, the same result as if each sign_char in all_sign_number_aft were '9', interpreting the instance of all_sign_number as either floating_LHS_sign number (if a radix and all_sign_number_aft are present), or as floating_LHS_sign otherwise. 67

An instance of all_currency_number maps to: 68

- a string of all spaces if the displayed magnitude of Item is zero and the instance of all_currency_number does not have a radix at its last character position; 69
- otherwise, the same result as if each currency_char in all_currency_number_aft were '9', interpreting the instance of all_currency_number as floating_$_currency number or 70

floating_#_currency number (if a radix and all_currency_number_aft are present), or as floating_$_currency or floating_#_currency otherwise.

Examples

71/5 {*AI12-0429-1*} *Examples of use of edited output; in the result string values shown below, 'b' represents the space character:*

```
72      Item:          Picture and Result Strings:
73/3    {AI05-0248-1} 123456.78     Picture:  "-###**_***_**9.99"
                      Result:   "bbb$***123,456.78"
                                "bbFF***123.456,78" (currency = "FF",
                                                     separator = '.',
                                                     radix mark = ',')
74/1    {8652/0089} {AI95-00070} 123456.78     Picture:  "-$**_***_**9.99"
                      Result:   "b$***123,456.78"
                               "bFF***123.456,78" (currency = "FF",
                                                   separator = '.',
                                                   radix mark = ',')
75      0.0           Picture: "-$$$$$$.$$"
                      Result:  "bbbbbbbbbb"
76      0.20          Picture: "-$$$$$$.$$"
                      Result:  "bbbbbb$.20"
77      -1234.565     Picture: "<<<<_<<<.<<###>"
                      Result:  "bb(1,234.57DMb)"  (currency = "DM")
78      12345.67      Picture: "###_###_##9.99"
                      Result:  "bbCHF12,345.67"   (currency = "CHF")
```

Wording Changes from Ada 95

78.a/2 {*8652/0089*} {*AI95-00070-01*} **Corrigendum:** Corrected the picture string example.

F.3.3 The Package Text_IO.Editing

1 The package Text_IO.Editing provides a private type Picture with associated operations, and a generic package Decimal_Output. An object of type Picture is composed from a well-formed picture String (see F.3.1) and a Boolean item indicating whether a zero numeric value will result in an edited output string of all space characters. The package Decimal_Output contains edited output subprograms implementing the effects defined in F.3.2.

Static Semantics

2 The library package Text_IO.Editing has the following declaration:

```
3/5     {AI12-0241-1} {AI12-0302-1} package Ada.Text_IO.Editing
           with Nonblocking, Global => in out synchronized is
4          type Picture is private;
5          function Valid (Pic_String      : in String;
                           Blank_When_Zero : in Boolean := False) return Boolean;
6          function To_Picture (Pic_String      : in String;
                                Blank_When_Zero : in Boolean := False)
              return Picture;
7          function Pic_String      (Pic : in Picture) return String;
           function Blank_When_Zero (Pic : in Picture) return Boolean;
8          Max_Picture_Length  : constant := implementation_defined;
9          Picture_Error       : exception;
```

```
   Default_Currency    : constant String    := "$";                                    10
   Default_Fill        : constant Character := '*';
   Default_Separator   : constant Character := ',';
   Default_Radix_Mark  : constant Character := '.';

   generic                                                                             11
      type Num is delta <> digits <>;
      Default_Currency   : in String    := Text_IO.Editing.Default_Currency;
      Default_Fill       : in Character := Text_IO.Editing.Default_Fill;
      Default_Separator  : in Character :=
                              Text_IO.Editing.Default_Separator;
      Default_Radix_Mark : in Character :=
                              Text_IO.Editing.Default_Radix_Mark;
   package Decimal_Output is
      function Length (Pic      : in Picture;
                       Currency : in String := Default_Currency)
         return Natural;

      function Valid (Item     : in Num;                                             12
                      Pic      : in Picture;
                      Currency : in String := Default_Currency)
         return Boolean;

      function Image (Item       : in Num;                                           13
                      Pic        : in Picture;
                      Currency   : in String    := Default_Currency;
                      Fill       : in Character := Default_Fill;
                      Separator  : in Character := Default_Separator;
                      Radix_Mark : in Character := Default_Radix_Mark)
         return String;

{AI12-0241-1}       procedure Put (File       : in File_Type;                       14/5
                       Item       : in Num;
                       Pic        : in Picture;
                       Currency   : in String    := Default_Currency;
                       Fill       : in Character := Default_Fill;
                       Separator  : in Character := Default_Separator;
                       Radix_Mark : in Character := Default_Radix_Mark)
         with Nonblocking => False;

{AI12-0241-1}       procedure Put (Item       : in Num;                             15/5
                       Pic        : in Picture;
                       Currency   : in String    := Default_Currency;
                       Fill       : in Character := Default_Fill;
                       Separator  : in Character := Default_Separator;
                       Radix_Mark : in Character := Default_Radix_Mark)
         with Nonblocking => False;

      procedure Put (To         : out String;                                        16
                     Item       : in Num;
                     Pic        : in Picture;
                     Currency   : in String    := Default_Currency;
                     Fill       : in Character := Default_Fill;
                     Separator  : in Character := Default_Separator;
                     Radix_Mark : in Character := Default_Radix_Mark);
   end Decimal_Output;
private
   ... -- not specified by the language
end Ada.Text_IO.Editing;
```

Implementation defined: The value of Max_Picture_Length in the package Text_IO.Editing 16.a

The exception Constraint_Error is raised if the Image function or any of the Put procedures is invoked with a null string for Currency. 17

```
function Valid (Pic_String      : in String;
                Blank_When_Zero : in Boolean := False) return Boolean;
```

Valid returns True if Pic_String is a well-formed picture String (see F.3.1) the length of whose expansion does not exceed Max_Picture_Length, and if either Blank_When_Zero is False or Pic_String contains no '*'.

```
function To_Picture (Pic_String      : in String;
                     Blank_When_Zero : in Boolean := False)
   return Picture;
```

To_Picture returns a result Picture such that the application of the function Pic_String to this result yields an expanded picture String equivalent to Pic_String, and such that Blank_When_Zero applied to the result Picture is the same value as the parameter Blank_When_Zero. Picture_Error is raised if not Valid(Pic_String, Blank_When_Zero).

```
function Pic_String      (Pic : in Picture) return String;

function Blank_When_Zero (Pic : in Picture) return Boolean;
```

If Pic is To_Picture(String_Item, Boolean_Item) for some String_Item and Boolean_Item, then:

- Pic_String(Pic) returns an expanded picture String equivalent to String_Item and with any lower-case letter replaced with its corresponding upper-case form, and
- Blank_When_Zero(Pic) returns Boolean_Item.

If Pic_1 and Pic_2 are objects of type Picture, then "="(Pic_1, Pic_2) is True when

- Pic_String(Pic_1) = Pic_String(Pic_2), and
- Blank_When_Zero(Pic_1) = Blank_When_Zero(Pic_2).

```
function Length (Pic      : in Picture;
                 Currency : in String := Default_Currency)
   return Natural;
```

Length returns Pic_String(Pic)'Length + Currency_Length_Adjustment – Radix_Adjustment where

- Currency_Length_Adjustment =
  - Currency'Length – 1 if there is some occurrence of '$' in Pic_String(Pic), and
  - 0 otherwise.
- Radix_Adjustment =
  - 1 if there is an occurrence of 'V' or 'v' in Pic_Str(Pic), and
  - 0 otherwise.

```
function Valid (Item     : in Num;
                Pic      : in Picture;
                Currency : in String := Default_Currency)
   return Boolean;
```

Valid returns True if Image(Item, Pic, Currency) does not raise Layout_Error, and returns False otherwise.

```
function Image (Item       : in Num;
                Pic        : in Picture;
                Currency   : in String    := Default_Currency;
                Fill       : in Character := Default_Fill;
                Separator  : in Character := Default_Separator;
                Radix_Mark : in Character := Default_Radix_Mark)
   return String;
```

Image returns the edited output String as defined in F.3.2 for Item, Pic_String(Pic), Blank_When_Zero(Pic), Currency, Fill, Separator, and Radix_Mark. If these rules identify a layout error, then Image raises the exception Layout_Error. 40

```
procedure Put (File       : in File_Type;                                    41
               Item       : in Num;
               Pic        : in Picture;
               Currency   : in String    := Default_Currency;
               Fill       : in Character := Default_Fill;
               Separator  : in Character := Default_Separator;
               Radix_Mark : in Character := Default_Radix_Mark);

procedure Put (Item       : in Num;
               Pic        : in Picture;
               Currency   : in String    := Default_Currency;
               Fill       : in Character := Default_Fill;
               Separator  : in Character := Default_Separator;
               Radix_Mark : in Character := Default_Radix_Mark);
```

Each of these Put procedures outputs Image(Item, Pic, Currency, Fill, Separator, Radix_Mark) consistent with the conventions for Put for other real types in case of bounded line length (see A.10.6, “Get and Put Procedures”). 42

```
procedure Put (To         : out String;                                      43
               Item       : in Num;
               Pic        : in Picture;
               Currency   : in String    := Default_Currency;
               Fill       : in Character := Default_Fill;
               Separator  : in Character := Default_Separator;
               Radix_Mark : in Character := Default_Radix_Mark);
```

{*AI05-0264-1*} Put copies Image(Item, Pic, Currency, Fill, Separator, Radix_Mark) to the given string, right justified. Otherwise, unassigned Character values in To are assigned the space character. If To'Length is less than the length of the string resulting from Image, then Layout_Error is raised. 44/3

Implementation Requirements

Max_Picture_Length shall be at least 30. The implementation shall support currency strings of length up to at least 10, both for Default_Currency in an instantiation of Decimal_Output, and for Currency in an invocation of Image or any of the Put procedures. 45

Discussion: This implies that a picture string with character replications need not be supported (i.e., To_Picture will raise Picture_Error) if its expanded form exceeds 30 characters. 45.a

Discussion: {*AI12-0450-1*} The rules for edited output were based on the 1985 version of COBOL (ANSI X3.23:1985, endorsed by ISO as ISO 1989-1985), with the following differences: 52.a/5

- The COBOL provisions for picture string localization and for 'P' format are absent from Ada. 52.b/5
- The following Ada facilities are not in the 1985 version of COBOL: 52.c/5
  - currency symbol placement after the number; 52.d/5
  - localization of edited output string for multi-character currency string values, including support for both length-preserving and length-expanding currency symbols in picture strings; 52.e/5
  - localization of the radix mark, digits separator, and fill character; and 52.f/5
  - parenthesization of negative values. 52.g/5

{*AI12-0450-1*} The value of 30 for Max_Picture_Length is the same limit as in COBOL. 52.h/5

Reason: There are several reasons we have not adopted the COBOL-style permission to provide a single-character replacement in the picture string for the `$' as currency symbol, or to interchange the roles of `.' and `,' in picture strings 52.i

- It would have introduced considerable complexity into Ada, as well as confusion between run-time and compile-time character interpretation, since picture Strings are dynamically computable in Ada, in contrast with COBOL 52.j

52.k
- Ada's rules for real literals provide a natural interpretation of `_' as digits separator and `.' for radix mark; it is not essential to allow these to be localized in picture strings, since Ada does not allow them to be localized in real literals.

52.l
- The COBOL restriction for the currency symbol in a picture string to be replaced by a single character currency symbol is a compromise solution. For general international usage a mechanism is needed to localize the edited output to be a multi-character currency string. Allowing a single-Character localization for the picture Character, and a multiple-character localization for the currency string, would be an unnecessary complication.

F.3.4 The Package Wide_Text_IO.Editing

Static Semantics

1 The child package Wide_Text_IO.Editing has the same contents as Text_IO.Editing, except that:

2
- each occurrence of Character is replaced by Wide_Character,

3
- each occurrence of Text_IO is replaced by Wide_Text_IO,

4
- the subtype of Default_Currency is Wide_String rather than String, and

5
- each occurrence of String in the generic package Decimal_Output is replaced by Wide_String.

5.a **Implementation defined:** The value of Max_Picture_Length in the package Wide_Text_IO.Editing

6 NOTE Each of the functions Wide_Text_IO.Editing.Valid, To_Picture, and Pic_String has String (versus Wide_String) as its parameter or result subtype, since a picture String is not localizable.

F.3.5 The Package Wide_Wide_Text_IO.Editing

Static Semantics

1/2 {*AI95-00285-01*} The child package Wide_Wide_Text_IO.Editing has the same contents as Text_IO.Editing, except that:

2/2
- each occurrence of Character is replaced by Wide_Wide_Character,

3/2
- each occurrence of Text_IO is replaced by Wide_Wide_Text_IO,

4/2
- the subtype of Default_Currency is Wide_Wide_String rather than String, and

5/2
- each occurrence of String in the generic package Decimal_Output is replaced by Wide_Wide_String.

5.a/2 **Implementation defined:** The value of Max_Picture_Length in the package Wide_Wide_Text_IO.Editing

6/2 NOTE {*AI95-00285-01*} Each of the functions Wide_Wide_Text_IO.Editing.Valid, To_Picture, and Pic_String has String (versus Wide_Wide_String) as its parameter or result subtype, since a picture String is not localizable.

Extensions to Ada 95

6.a/2 {*AI95-00285-01*} Package Wide_Wide_Text_IO.Editing is new; it supports 32-bit character strings. (Shouldn't it have been “Widest_Text_IO.Editing”? :-)

Annex G
(normative)
Numerics

The Numerics Annex specifies 1

- features for complex arithmetic, including complex I/O; 2
- a mode ("strict mode"), in which the predefined arithmetic operations of floating point and fixed point types and the functions and operations of various predefined packages have to provide guaranteed accuracy or conform to other numeric performance requirements, which the Numerics Annex also specifies; 3
- {*AI12-0445-1*} a mode ("relaxed mode"), in which there are no accuracy or other numeric performance requirements to be satisfied, as for implementations not conforming to the Numerics Annex; 4/5
- {*AI95-00296-01*} models of floating point and fixed point arithmetic on which the accuracy requirements of strict mode are based; 5/2
- {*AI95-00296-01*} the definitions of the model-oriented attributes of floating point types that apply in the strict mode; and 6/2
- {*AI95-00296-01*} features for the manipulation of real and complex vectors and matrices. 6.1/2

Implementation Advice

{*AI05-0229-1*} If Fortran (respectively, C) is widely supported in the target environment, implementations supporting the Numerics Annex should provide the child package Interfaces.Fortran (respectively, Interfaces.C) specified in Annex B and should support a *convention*_identifier of Fortran (respectively, C) for the Convention aspect (see Annex B), thus allowing Ada programs to interface with programs written in that language. 7/3

Implementation Advice: If Fortran (respectively, C) is supported in the target environment, then interfacing to Fortran (respectively, C) should be supported as specified in Annex B. 7.a.1/2

Extensions to Ada 83

This Annex is new to Ada 95. 7.a

G.1 Complex Arithmetic

Types and arithmetic operations for complex arithmetic are provided in Generic_Complex_Types, which is defined in G.1.1. Implementation-defined approximations to the complex analogs of the mathematical functions known as the "elementary functions" are provided by the subprograms in Generic_Complex_-Elementary_Functions, which is defined in G.1.2. Both of these library units are generic children of the predefined package Numerics (see A.5). Nongeneric equivalents of these generic packages for each of the predefined floating point types are also provided as children of Numerics. 1

Implementation defined: The accuracy actually achieved by the complex elementary functions and by other complex arithmetic operations. 1.a

Discussion: Complex arithmetic is defined in the Numerics Annex, rather than in the core, because it is considered to be a specialized need of (some) numeric applications. 1.b

G.1.1 Complex Types

Static Semantics

1 The generic library package Numerics.Generic_Complex_Types has the following declaration:

2/5
```
{8652/0020} {AI95-00126-01} {AI12-0241-1} generic
   type Real is digits <>;
package Ada.Numerics.Generic_Complex_Types
   with Pure, Nonblocking is
```

3
```
   type Complex is
      record
         Re, Im : Real'Base;
      end record;
```

4/5
```
{AI95-00161-01} {AI95-0399-1}    type Imaginary is private
      with Preelaborable_Initialization;
```

5
```
   i : constant Imaginary;
   j : constant Imaginary;
```

6
```
   function Re (X : Complex)   return Real'Base;
   function Im (X : Complex)   return Real'Base;
   function Im (X : Imaginary) return Real'Base;
```

7
```
   procedure Set_Re (X  : in out Complex;
                     Re : in     Real'Base);
   procedure Set_Im (X  : in out Complex;
                     Im : in     Real'Base);
   procedure Set_Im (X  :    out Imaginary;
                     Im : in     Real'Base);
```

8
```
   function Compose_From_Cartesian (Re, Im : Real'Base) return Complex;
   function Compose_From_Cartesian (Re     : Real'Base) return Complex;
   function Compose_From_Cartesian (Im     : Imaginary) return Complex;
```

9
```
   function Modulus (X     : Complex) return Real'Base;

   function "/" (Left : Imaginary; Right : Real'Base) return Imaginary;
   function "/" (Left : Real'Base; Right : Imaginary) return Imaginary;

private                                                                                       22

   type Imaginary is new Real'Base;                                                           23
   i : constant Imaginary := 1.0;
   j : constant Imaginary := 1.0;

end Ada.Numerics.Generic_Complex_Types;                                                       24
```

{*8652/0020*} {*AI95-00126-01*} The library package Numerics.Complex_Types is declared pure and defines the same types, constants, and subprograms as Numerics.Generic_Complex_Types, except that the predefined type Float is systematically substituted for Real'Base throughout. Nongeneric equivalents of Numerics.Generic_Complex_Types for each of the other predefined floating point types are defined similarly, with the names Numerics.Short_Complex_Types, Numerics.Long_Complex_Types, etc. 25/1

Reason: The nongeneric equivalents are provided to allow the programmer to construct simple mathematical applications without being required to understand and use generics. 25.a

Reason: The nongeneric equivalents all export the types Complex and Imaginary and the constants i and j (rather than uniquely named types and constants, such as Short_Complex, Long_Complex, etc.) to preserve their equivalence to actual instantiations of the generic package and to allow the programmer to change the precision of an application globally by changing a single context clause. 25.b

Ramification: {*AI12-0241-1*} A pure unit is always nonblocking, so we don't need to talk about the Nonblocking aspect of these packages. Similarly, a pure unit always has the Global aspect set to **null**, so we don't need to talk about that, either. 25.c/5

{*AI95-00434-01*} [Complex is a visible type with Cartesian components.] 26/2

Reason: The Cartesian representation is far more common than the polar representation, in practice. The accuracy of the results of the complex arithmetic operations and of the complex elementary functions is dependent on the representation; thus, implementers need to know that representation. The type is visible so that complex “literals” can be written in aggregate notation, if desired. 26.a

[Imaginary is a private type; its full type is derived from Real'Base.] 27

Reason: The Imaginary type and the constants i and j are provided for two reasons: 27.a

- They allow complex “literals” to be written in the alternate form of *a* + *b**i (or *a* + *b**j), if desired. Of course, in some contexts the sum will need to be parenthesized. 27.b

27.c/5 • {*AI12-0437-1*} {*AI12-0453-1*} When an Ada binding to ISO/IEC 60559:2020 that provides (signed) infinities as the result of operations that overflow becomes available, it will be important to allow arithmetic between pure-imaginary and complex operands without requiring the former to be represented as (or promoted to) complex values with a real component of zero. For example, the multiplication of *a* + *b**i by *d**i should yield –*b*· *d* + *a*· *d**i, but if one cannot avoid representing the pure-imaginary value *d**i as the complex value 0.0 + *d**i, then a NaN ("Not-a-Number") could be produced as the result of multiplying *a* by 0.0 (for example, when *a* is infinite); the NaN could later trigger an exception. Providing the Imaginary type and overloadings of the arithmetic operators for mixtures of Imaginary and Complex operands gives the programmer the same control over avoiding premature coercion of pure-imaginary values to complex as is already provided for pure-real values.

27.d **Reason:** The Imaginary type is private, rather than being visibly derived from Real'Base, for two reasons:

27.e • to preclude implicit conversions of real literals to the Imaginary type (such implicit conversions would make many common arithmetic expressions ambiguous); and

27.f • to suppress the implicit derivation of the multiplication, division, and absolute value operators with Imaginary operands and an Imaginary result (the result type would be incorrect).

27.g/5 **Reason:** {*AI12-0453-1*} The base subtype Real'Base is used for the component type of Complex, the parent type of Imaginary, and the parameter and result types of some of the subprograms to maximize the chances of being able to pass meaningful values into the subprograms and receive meaningful results back. The generic formal parameter Real therefore plays only one role, that of providing the precision to be maintained in complex arithmetic calculations. Thus, the subprograms in Numerics.Generic_Complex_Types share with those in Numerics.Generic_Elementary_Functions, and indeed even with the predefined arithmetic operations (see 4.5), the property of being free of range checks on input and output, that is, of being able to exploit the base range of the relevant floating point type fully. As a result, the user loses the ability to impose application-oriented bounds on the range of values that the components of a complex variable can acquire; however, it can be argued that few, if any, applications have a naturally square domain (as opposed to a circular domain) anyway.

28 The arithmetic operations and the Re, Im, Modulus, Argument, and Conjugate functions have their usual mathematical meanings. When applied to a parameter of pure-imaginary type, the “imaginary-part” function Im yields the value of its parameter, as the corresponding real value. The remaining subprograms have the following meanings:

28.a **Reason:** The middle case can be understood by considering the parameter of pure-imaginary type to represent a complex value with a zero real part.

29 • The Set_Re and Set_Im procedures replace the designated component of a complex parameter with the given real value; applied to a parameter of pure-imaginary type, the Set_Im procedure replaces the value of that parameter with the imaginary value corresponding to the given real value.

30 • The Compose_From_Cartesian function constructs a complex value from the given real and imaginary components. If only one component is given, the other component is implicitly zero.

31 • The Compose_From_Polar function constructs a complex value from the given modulus (radius) and argument (angle). When the value of the parameter Modulus is positive (resp., negative), the result is the complex value represented by the point in the complex plane lying at a distance from the origin given by the absolute value of Modulus and forming an angle measured counterclockwise from the positive (resp., negative) real axis given by the value of the parameter Argument.

32 When the Cycle parameter is specified, the result of the Argument function and the parameter Argument of the Compose_From_Polar function are measured in units such that a full cycle of revolution has the given value; otherwise, they are measured in radians.

33 The computed results of the mathematically multivalued functions are rendered single-valued by the following conventions, which are meant to imply the principal branch:

34 • The result of the Modulus function is nonnegative.

35 • The result of the Argument function is in the quadrant containing the point in the complex plane represented by the parameter X. This may be any quadrant (I through IV); thus, the range of the Argument function is approximately –π to π (–Cycle/2.0 to Cycle/2.0, if the parameter Cycle is

specified). When the point represented by the parameter X lies on the negative real axis, the result approximates

- π (resp., –π) when the sign of the imaginary component of X is positive (resp., negative), if Real'Signed_Zeros is True; 36
- π, if Real'Signed_Zeros is False. 37

- Because a result lying on or near one of the axes may not be exactly representable, the approximation inherent in computing the result may place it in an adjacent quadrant, close to but on the wrong side of the axis. 38

Dynamic Semantics

The exception Numerics.Argument_Error is raised by the Argument and Compose_From_Polar functions with specified cycle, signaling a parameter value outside the domain of the corresponding mathematical function, when the value of the parameter Cycle is zero or negative. 39

The exception Constraint_Error is raised by the division operator when the value of the right operand is zero, and by the exponentiation operator when the value of the left operand is zero and the value of the exponent is negative, provided that Real'Machine_Overflows is True; when Real'Machine_Overflows is False, the result is unspecified. [Constraint_Error can also be raised when a finite result overflows (see G.2.6).] 40

Discussion: {*AI12-0437-1*} It is anticipated that an Ada binding to ISO/IEC 60559:2020 will be developed in the future. As part of such a binding, the Machine_Overflows attribute of a conformant floating point type will be specified to yield False, which will permit implementations of the complex arithmetic operations to deliver results with an infinite component (and set the overflow flag defined by the binding) instead of raising Constraint_Error in overflow situations, when traps are disabled. Similarly, it is appropriate for the complex arithmetic operations to deliver results with infinite components (and set the zero-divide flag defined by the binding) instead of raising Constraint_Error in the situations defined above, when traps are disabled. Finally, such a binding should also specify the behavior of the complex arithmetic operations, when sensible, given operands with infinite components. 40.a/5

Implementation Requirements

In the implementation of Numerics.Generic_Complex_Types, the range of intermediate values allowed during the calculation of a final result shall not be affected by any range constraint of the subtype Real. 41

Implementation Note: Implementations of Numerics.Generic_Complex_Types written in Ada should therefore avoid declaring local variables of subtype Real; the subtype Real'Base should be used instead. 41.a

In the following cases, evaluation of a complex arithmetic operation shall yield the *prescribed result*, provided that the preceding rules do not call for an exception to be raised: 42

- The results of the Re, Im, and Compose_From_Cartesian functions are exact. 43
- The real (resp., imaginary) component of the result of a binary addition operator that yields a result of complex type is exact when either of its operands is of pure-imaginary (resp., real) type. 44

Ramification: The result of the addition operator is exact when one of its operands is of real type and the other is of pure-imaginary type. In this particular case, the operator is analogous to the Compose_From_Cartesian function; it performs no arithmetic. 44.a

- The real (resp., imaginary) component of the result of a binary subtraction operator that yields a result of complex type is exact when its right operand is of pure-imaginary (resp., real) type. 45
- The real component of the result of the Conjugate function for the complex type is exact. 46
- When the point in the complex plane represented by the parameter X lies on the nonnegative real axis, the Argument function yields a result of zero. 47

Discussion: Argument(X + i*Y) is analogous to *EF*.Arctan(Y, X), where *EF* is an appropriate instance of Numerics.Generic_Elementary_Functions, except when X and Y are both zero, in which case the former yields the value zero while the latter raises Numerics.Argument_Error. 47.a

48 • When the value of the parameter Modulus is zero, the Compose_From_Polar function yields a result of zero.

49 • When the value of the parameter Argument is equal to a multiple of the quarter cycle, the result of the Compose_From_Polar function with specified cycle lies on one of the axes. In this case, one of its components is zero, and the other has the magnitude of the parameter Modulus.

50 • Exponentiation by a zero exponent yields the value one. Exponentiation by a unit exponent yields the value of the left operand. Exponentiation of the value one yields the value one. Exponentiation of the value zero yields the value zero, provided that the exponent is nonzero. When the left operand is of pure-imaginary type, one component of the result of the exponentiation operator is zero.

51 When the result, or a result component, of any operator of Numerics.Generic_Complex_Types has a mathematical definition in terms of a single arithmetic or relational operation, that result or result component exhibits the accuracy of the corresponding operation of the type Real.

52 Other accuracy requirements for the Modulus, Argument, and Compose_From_Polar functions, and accuracy requirements for the multiplication of a pair of complex operands or for division by a complex operand, all of which apply only in the strict mode, are given in G.2.6.

53 The sign of a zero result or zero result component yielded by a complex arithmetic operation or function is implementation defined when Real'Signed_Zeros is True.

53.a **Implementation defined:** The sign of a zero result (or a component thereof) from any operator or function in Numerics.Generic_Complex_Types, when Real'Signed_Zeros is True.

Implementation Permissions

54/5 {*AI12-0444-1*} The nongeneric equivalent packages can be actual instantiations of the generic package for the appropriate predefined type, though that is not required.

55/2 {*8652/0091*} {*AI95-00434-01*} Implementations may obtain the result of exponentiation of a complex or pure-imaginary operand by repeated complex multiplication, with arbitrary association of the factors and with a possible final complex reciprocation (when the exponent is negative). Implementations are also permitted to obtain the result of exponentiation of a complex operand, but not of a pure-imaginary operand, by converting the left operand to a polar representation; exponentiating the modulus by the given exponent; multiplying the argument by the given exponent; and reconverting to a Cartesian representation. Because of this implementation freedom, no accuracy requirement is imposed on complex exponentiation (except for the prescribed results given above, which apply regardless of the implementation method chosen).

Implementation Advice

56/5 {*AI12-0437-1*} Because the usual mathematical meaning of multiplication of a complex operand and a real operand is that of the scaling of both components of the former by the latter, an implementation should not perform this operation by first promoting the real operand to complex type and then performing a full complex multiplication. In systems that, in the future, support an Ada binding to ISO/IEC 60559:2020, the latter technique will not generate the required result when one of the components of the complex operand is infinite. (Explicit multiplication of the infinite component by the zero component obtained during promotion yields a NaN that propagates into the final result.) Analogous advice applies in the case of multiplication of a complex operand and a pure-imaginary operand, and in the case of division of a complex operand by a real or pure-imaginary operand.

56.a/2 **Implementation Advice:** Mixed real and complex operations (as well as pure-imaginary and complex operations) should not be performed by converting the real (resp. pure-imaginary) operand to complex.

{*AI12-0437-1*} Likewise, because the usual mathematical meaning of addition of a complex operand and a real operand is that the imaginary operand remains unchanged, an implementation should not perform this operation by first promoting the real operand to complex type and then performing a full complex addition. In implementations in which the Signed_Zeros attribute of the component type is True (and which therefore conform to ISO/IEC 60559:2020 in regard to the handling of the sign of zero in predefined arithmetic operations), the latter technique will not generate the required result when the imaginary component of the complex operand is a negatively signed zero. (Explicit addition of the negative zero to the zero obtained during promotion yields a positive zero.) Analogous advice applies in the case of addition of a complex operand and a pure-imaginary operand, and in the case of subtraction of a complex operand and a real or pure-imaginary operand. 57/5

Implementations in which Real'Signed_Zeros is True should attempt to provide a rational treatment of the signs of zero results and result components. As one example, the result of the Argument function should have the sign of the imaginary component of the parameter X when the point represented by that parameter lies on the positive real axis; as another, the sign of the imaginary component of the Compose_From_Polar function should be the same as (resp., the opposite of) that of the Argument parameter when that parameter has a value of zero and the Modulus parameter has a nonnegative (resp., negative) value. 58

Implementation Advice: If Real'Signed_Zeros is True for Numerics.Generic_Complex_Types, a rational treatment of the signs of zero results and result components should be provided. 58.a.1/3

Wording Changes from Ada 83

The semantics of Numerics.Generic_Complex_Types differs from Generic_Complex_Types as defined in ISO/IEC CD 13813 (for Ada 83) in the following ways: 58.a

- The generic package is a child of the package defining the Argument_Error exception. 58.b
- The nongeneric equivalents export types and constants with the same names as those exported by the generic package, rather than with names unique to the package. 58.c
- Implementations are not allowed to impose an optional restriction that the generic actual parameter associated with Real be unconstrained. (In view of the ability to declare variables of subtype Real'Base in implementations of Numerics.Generic_Complex_Types, this flexibility is no longer needed.) 58.d
- The dependence of the Argument function on the sign of a zero parameter component is tied to the value of Real'Signed_Zeros. 58.e
- Conformance to accuracy requirements is conditional. 58.f

Extensions to Ada 95

{*AI95-00161-01*} **Amendment Correction:** Added a pragma Preelaborable_Initialization to type Imaginary, so that it can be used in preelaborated units. 58.g/2

Wording Changes from Ada 95

{*8652/0020*} {*AI95-00126-01*} **Corrigendum:** Explicitly stated that the nongeneric equivalents of Generic_Complex_Types are pure. 58.h/2

G.1.2 Complex Elementary Functions

Static Semantics

The generic library package Numerics.Generic_Complex_Elementary_Functions has the following declaration: 1

2/5
```
{AI95-00434-01} {AI12-0241-1} with Ada.Numerics.Generic_Complex_Types;
generic
   with package Complex_Types is
         new Ada.Numerics.Generic_Complex_Types (<>);
   use Complex_Types;
package Ada.Numerics.Generic_Complex_Elementary_Functions
   with Pure, Nonblocking is
```

3
```
   function Sqrt (X : Complex)   return Complex;
   function Log  (X : Complex)   return Complex;
   function Exp  (X : Complex)   return Complex;
   function Exp  (X : Imaginary) return Complex;
   function "**" (Left : Complex;   Right : Complex)   return Complex;
   function "**" (Left : Complex;   Right : Real'Base) return Complex;
   function "**" (Left : Real'Base; Right : Complex)   return Complex;
```

4
```
   function Sin (X : Complex) return Complex;
   function Cos (X : Complex) return Complex;
   function Tan (X : Complex) return Complex;
   function Cot (X : Complex) return Complex;
```

5
```
   function Arcsin (X : Complex) return Complex;
   function Arccos (X : Complex) return Complex;
   function Arctan (X : Complex) return Complex;
   function Arccot (X : Complex) return Complex;
```

6
```
   function Sinh (X : Complex) return Complex;
   function Cosh (X : Complex) return Complex;
   function Tanh (X : Complex) return Complex;
   function Coth (X : Complex) return Complex;
```

7
```
   function Arcsinh (X : Complex) return Complex;
   function Arccosh (X : Complex) return Complex;
   function Arctanh (X : Complex) return Complex;
   function Arccoth (X : Complex) return Complex;
```

8
```
end Ada.Numerics.Generic_Complex_Elementary_Functions;
```

9/1 {*8652/0020*} {*AI95-00126-01*} The library package Numerics.Complex_Elementary_Functions is declared pure and defines the same subprograms as Numerics.Generic_Complex_Elementary_Functions, except that the predefined type Float is systematically substituted for Real'Base, and the Complex and Imaginary types exported by Numerics.Complex_Types are systematically substituted for Complex and Imaginary, throughout. Nongeneric equivalents of Numerics.Generic_Complex_Elementary_Functions corresponding to each of the other predefined floating point types are defined similarly, with the names Numerics.Short_Complex_Elementary_Functions, Numerics.Long_Complex_Elementary_Functions, etc.

9.a **Reason:** The nongeneric equivalents are provided to allow the programmer to construct simple mathematical applications without being required to understand and use generics.

10 The overloading of the Exp function for the pure-imaginary type is provided to give the user an alternate way to compose a complex value from a given modulus and argument. In addition to Compose_From_Polar(Rho, Theta) (see G.1.1), the programmer may write Rho * Exp(i * Theta).

11 The imaginary (resp., real) component of the parameter X of the forward hyperbolic (resp., trigonometric) functions and of the Exp function (and the parameter X, itself, in the case of the overloading of the Exp function for the pure-imaginary type) represents an angle measured in radians, as does the imaginary (resp., real) component of the result of the Log and inverse hyperbolic (resp., trigonometric) functions.

12 The functions have their usual mathematical meanings. However, the arbitrariness inherent in the placement of branch cuts, across which some of the complex elementary functions exhibit discontinuities, is eliminated by the following conventions:

13 • The imaginary component of the result of the Sqrt and Log functions is discontinuous as the parameter X crosses the negative real axis.

- The result of the exponentiation operator when the left operand is of complex type is discontinuous as that operand crosses the negative real axis. 14
- {*AI95-00185-01*} The imaginary component of the result of the Arcsin, Arccos, and Arctanh functions is discontinuous as the parameter X crosses the real axis to the left of –1.0 or the right of 1.0. 15/2
- {*AI95-00185-01*} The real component of the result of the Arctan and Arcsinh functions is discontinuous as the parameter X crosses the imaginary axis below –*i* or above *i*. 16/2
- {*AI95-00185-01*} The real component of the result of the Arccot function is discontinuous as the parameter X crosses the imaginary axis below –*i* or above *i*. 17/2
- The imaginary component of the Arccosh function is discontinuous as the parameter X crosses the real axis to the left of 1.0. 18
- The imaginary component of the result of the Arccoth function is discontinuous as the parameter X crosses the real axis between –1.0 and 1.0. 19

Discussion: {*AI95-00185-01*} The branch cuts come from the fact that the functions in question are really multi-valued in the complex domain, and that we have to pick one *principal value* to be the result of the function. Evidently we have much freedom in choosing where the branch cuts lie. However, we are adhering to the following principles which seem to lead to the more *natural* definitions: 19.a/2

- A branch cut should not intersect the real axis at a place where the corresponding real function is well-defined (in other words, the complex function should be an extension of the corresponding real function). 19.b/2
- Because all the functions in question are analytic, to ensure power series validity for the principal value, the branch cuts should be invariant by complex conjugation. 19.c/2
- For odd functions, to ensure that the principal value remains an odd function, the branch cuts should be invariant by reflection in the origin. 19.d/2

{*AI95-00185-01*} The computed results of the mathematically multivalued functions are rendered single-valued by the following conventions, which are meant to imply that the principal branch is an analytic continuation of the corresponding real-valued function in Numerics.Generic_Elementary_Functions. (For Arctan and Arccot, the single-argument function in question is that obtained from the two-argument version by fixing the second argument to be its default value.) 20/2

- The real component of the result of the Sqrt and Arccosh functions is nonnegative. 21
- The same convention applies to the imaginary component of the result of the Log function as applies to the result of the natural-cycle version of the Argument function of Numerics.Generic_Complex_Types (see G.1.1). 22
- The range of the real (resp., imaginary) component of the result of the Arcsin and Arctan (resp., Arcsinh and Arctanh) functions is approximately –π/2.0 to π/2.0. 23
- The real (resp., imaginary) component of the result of the Arccos and Arccot (resp., Arccoth) functions ranges from 0.0 to approximately π. 24
- The range of the imaginary component of the result of the Arccosh function is approximately –π to π. 25

In addition, the exponentiation operator inherits the single-valuedness of the Log function. 26

Dynamic Semantics

The exception Numerics.Argument_Error is raised by the exponentiation operator, signaling a parameter value outside the domain of the corresponding mathematical function, when the value of the left operand is zero and the real component of the exponent (or the exponent itself, when it is of real type) is zero. 27

The exception Constraint_Error is raised, signaling a pole of the mathematical function (analogous to dividing by zero), in the following cases, provided that Complex_Types.Real'Machine_Overflows is True: 28

29 • by the Log, Cot, and Coth functions, when the value of the parameter X is zero;

30 • by the exponentiation operator, when the value of the left operand is zero and the real component of the exponent (or the exponent itself, when it is of real type) is negative;

31 • by the Arctan and Arccot functions, when the value of the parameter X is ± *i*;

32 • by the Arctanh and Arccoth functions, when the value of the parameter X is ± 1.0.

33 [Constraint_Error can also be raised when a finite result overflows (see G.2.6); this may occur for parameter values sufficiently *near* poles, and, in the case of some of the functions, for parameter values having components of sufficiently large magnitude.] When Complex_Types.Real'Machine_Overflows is False, the result at poles is unspecified.

33.a **Reason:** The purpose of raising Constraint_Error (rather than Numerics.Argument_Error) at the poles of a function, when Float_Type'Machine_Overflows is True, is to provide continuous behavior as the actual parameters of the function approach the pole and finally reach it.

33.b/5 **Discussion:** {*AI12-0437-1*} It is anticipated that an Ada binding to ISO/IEC 60559:2020 will be developed in the future. As part of such a binding, the Machine_Overflows attribute of a conformant floating point type will be specified to yield False, which will permit implementations of the complex elementary functions to deliver results with an infinite component (and set the overflow flag defined by the binding) instead of raising Constraint_Error in overflow situations, when traps are disabled. Similarly, it is appropriate for the complex elementary functions to deliver results with an infinite component (and set the zero-divide flag defined by the binding) instead of raising Constraint_Error at poles, when traps are disabled. Finally, such a binding should also specify the behavior of the complex elementary functions, when sensible, given parameters with infinite components.

Implementation Requirements

34 In the implementation of Numerics.Generic_Complex_Elementary_Functions, the range of intermediate values allowed during the calculation of a final result shall not be affected by any range constraint of the subtype Complex_Types.Real.

34.a **Implementation Note:** Implementations of Numerics.Generic_Complex_Elementary_Functions written in Ada should therefore avoid declaring local variables of subtype Complex_Types.Real; the subtype Complex_Types.Real'Base should be used instead.

35 In the following cases, evaluation of a complex elementary function shall yield the *prescribed result* (or a result having the prescribed component), provided that the preceding rules do not call for an exception to be raised:

36 • When the parameter X has the value zero, the Sqrt, Sin, Arcsin, Tan, Arctan, Sinh, Arcsinh, Tanh, and Arctanh functions yield a result of zero; the Exp, Cos, and Cosh functions yield a result of one; the Arccos and Arccot functions yield a real result; and the Arccoth function yields an imaginary result.

37 • When the parameter X has the value one, the Sqrt function yields a result of one; the Log, Arccos, and Arccosh functions yield a result of zero; and the Arcsin function yields a real result.

38 • When the parameter X has the value –1.0, the Sqrt function yields the result

39 – *i* (resp., –*i*), when the sign of the imaginary component of X is positive (resp., negative), if Complex_Types.Real'Signed_Zeros is True;

40 – *i*, if Complex_Types.Real'Signed_Zeros is False;

41/2 • {*AI95-00434-01*} When the parameter X has the value –1.0, the Log function yields an imaginary result; and the Arcsin and Arccos functions yield a real result.

42 • When the parameter X has the value ± *i*, the Log function yields an imaginary result.

43 • Exponentiation by a zero exponent yields the value one. Exponentiation by a unit exponent yields the value of the left operand (as a complex value). Exponentiation of the value one yields the value one. Exponentiation of the value zero yields the value zero.

Discussion: It is possible to give many other prescribed results restricting the result to the real or imaginary axis when the parameter X is appropriately restricted to easily testable portions of the domain. We follow the proposed ISO/IEC standard for Generic_Complex_Elementary_Functions (for Ada 83), CD 13813, in not doing so, however. 43.a

Other accuracy requirements for the complex elementary functions, which apply only in the strict mode, are given in G.2.6. 44

The sign of a zero result or zero result component yielded by a complex elementary function is implementation defined when Complex_Types.Real'Signed_Zeros is True. 45

Implementation defined: The sign of a zero result (or a component thereof) from any operator or function in Numerics.Generic_Complex_Elementary_Functions, when Complex_Types.Real'Signed_Zeros is True. 45.a

Implementation Permissions

{*AI12-0444-1*} The nongeneric equivalent packages can be actual instantiations of the generic package with the appropriate predefined nongeneric equivalent of Numerics.Generic_Complex_Types, though that is not required; if they are, then the latter shall have been obtained by actual instantiation of Numerics.Generic_Complex_Types. 46/5

The exponentiation operator may be implemented in terms of the Exp and Log functions. Because this implementation yields poor accuracy in some parts of the domain, no accuracy requirement is imposed on complex exponentiation. 47

The implementation of the Exp function of a complex parameter X is allowed to raise the exception Constraint_Error, signaling overflow, when the real component of X exceeds an unspecified threshold that is approximately log(Complex_Types.Real'Safe_Last). This permission recognizes the impracticality of avoiding overflow in the marginal case that the exponential of the real component of X exceeds the safe range of Complex_Types.Real but both components of the final result do not. Similarly, the Sin and Cos (resp., Sinh and Cosh) functions are allowed to raise the exception Constraint_Error, signaling overflow, when the absolute value of the imaginary (resp., real) component of the parameter X exceeds an unspecified threshold that is approximately log(Complex_Types.Real'Safe_Last) + log(2.0). This permission recognizes the impracticality of avoiding overflow in the marginal case that the hyperbolic sine or cosine of the imaginary (resp., real) component of X exceeds the safe range of Complex_Types.Real but both components of the final result do not. 48

Implementation Advice

Implementations in which Complex_Types.Real'Signed_Zeros is True should attempt to provide a rational treatment of the signs of zero results and result components. For example, many of the complex elementary functions have components that are odd functions of one of the parameter components; in these cases, the result component should have the sign of the parameter component at the origin. Other complex elementary functions have zero components whose sign is opposite that of a parameter component at the origin, or is always positive or always negative. 49

Implementation Advice: If Complex_Types.Real'Signed_Zeros is True for Numerics.Generic_Complex_Elementary_Functions, a rational treatment of the signs of zero results and result components should be provided. 49.a.1/3

Wording Changes from Ada 83

The semantics of Numerics.Generic_Complex_Elementary_Functions differs from Generic_Complex_Elementary_Functions as defined in ISO/IEC CD 13814 (for Ada 83) in the following ways: 49.a

- The generic package is a child unit of the package defining the Argument_Error exception. 49.b
- The proposed Generic_Complex_Elementary_Functions standard (for Ada 83) specified names for the nongeneric equivalents, if provided. Here, those nongeneric equivalents are required. 49.c
- The generic package imports an instance of Numerics.Generic_Complex_Types rather than a long list of individual types and operations exported by such an instance. 49.d

49.e
- The dependence of the imaginary component of the Sqrt and Log functions on the sign of a zero parameter component is tied to the value of Complex_Types.Real'Signed_Zeros.

49.f
- Conformance to accuracy requirements is conditional.

Wording Changes from Ada 95

49.g/2 {*8652/0020*} {*AI95-00126-01*} **Corrigendum:** Explicitly stated that the nongeneric equivalents of Generic_Complex_Elementary_Functions are pure.

49.h/2 {*AI95-00185-01*} Corrected various inconsistencies in the definition of the branch cuts.

G.1.3 Complex Input-Output

1 The generic package Text_IO.Complex_IO defines procedures for the formatted input and output of complex values. The generic actual parameter in an instantiation of Text_IO.Complex_IO is an instance of Numerics.Generic_Complex_Types for some floating point subtype. Exceptional conditions are reported by raising the appropriate exception defined in Text_IO.

1.a **Implementation Note:** An implementation of Text_IO.Complex_IO can be built around an instance of Text_IO.Float_IO for the base subtype of Complex_Types.Real, where Complex_Types is the generic formal package parameter of Text_IO.Complex_IO. There is no need for an implementation of Text_IO.Complex_IO to parse real values.

Static Semantics

2 The generic library package Text_IO.Complex_IO has the following declaration:

2.a **Ramification:** Because this is a child of Text_IO, the declarations of the visible part of Text_IO are directly visible within it.

3/5
```
{AI12-0302-1} with Ada.Numerics.Generic_Complex_Types;
generic
   with package Complex_Types is
         new Ada.Numerics.Generic_Complex_Types (<>);
package Ada.Text_IO.Complex_IO
   with Global => in out synchronized is
```

4
```
   use Complex_Types;
```

5
```
   Default_Fore : Field := 2;
   Default_Aft  : Field := Real'Digits - 1;
   Default_Exp  : Field := 3;
```

6
```
   procedure Get (File  : in  File_Type;
                  Item  : out Complex;
                  Width : in  Field := 0);
   procedure Get (Item  : out Complex;
                  Width : in  Field := 0);
```

7
```
   procedure Put (File : in File_Type;
                  Item : in Complex;
                  Fore : in Field := Default_Fore;
                  Aft  : in Field := Default_Aft;
                  Exp  : in Field := Default_Exp);
   procedure Put (Item : in Complex;
                  Fore : in Field := Default_Fore;
                  Aft  : in Field := Default_Aft;
                  Exp  : in Field := Default_Exp);
```

8/5
```
{AI12-0241-1}    procedure Get (From : in  String;
                  Item : out Complex;
                  Last : out Positive)
      with Nonblocking;
   procedure Put (To   : out String;
                  Item : in  Complex;
                  Aft  : in  Field := Default_Aft;
                  Exp  : in  Field := Default_Exp)
      with Nonblocking;
```

```
end Ada.Text_IO.Complex_IO;
```

9

{*AI95-00328-01*} The library package Complex_Text_IO defines the same subprograms as Text_IO.Complex_IO, except that the predefined type Float is systematically substituted for Real, and the type Numerics.Complex_Types.Complex is systematically substituted for Complex throughout. Nongeneric equivalents of Text_IO.Complex_IO corresponding to each of the other predefined floating point types are defined similarly, with the names Short_Complex_Text_IO, Long_Complex_Text_IO, etc.

9.1/2

Reason: The nongeneric equivalents are provided to allow the programmer to construct simple mathematical applications without being required to understand and use generics.

9.a/2

The semantics of the Get and Put procedures are as follows:

10

```
procedure Get (File  : in  File_Type;
               Item  : out Complex;
               Width : in  Field := 0);
procedure Get (Item  : out Complex;
               Width : in  Field := 0);
```

11

{*8652/0092*} {*AI95-00029-01*} The input sequence is a pair of optionally signed real literals representing the real and imaginary components of a complex value. These components have the format defined for the corresponding Get procedure of an instance of Text_IO.Float_IO (see A.10.9) for the base subtype of Complex_Types.Real. The pair of components may be separated by a comma or surrounded by a pair of parentheses or both. Blanks are freely allowed before each of the components and before the parentheses and comma, if either is used. If the value of the parameter Width is zero, then

12/1

- line and page terminators are also allowed in these places;

13

- the components shall be separated by at least one blank or line terminator if the comma is omitted; and

14

- reading stops when the right parenthesis has been read, if the input sequence includes a left parenthesis, or when the imaginary component has been read, otherwise.

15

If a nonzero value of Width is supplied, then

15.1

- the components shall be separated by at least one blank if the comma is omitted; and

16

- exactly Width characters are read, or the characters (possibly none) up to a line terminator, whichever comes first (blanks are included in the count).

17

Reason: The parenthesized and comma-separated form is the form produced by Put on output (see below), and also by list-directed output in Fortran. The other allowed forms match several common styles of edit-directed output in Fortran, allowing most preexisting Fortran data files containing complex data to be read easily. When such files contain complex values with no separation between the real and imaginary components, the user will have to read those components separately, using an instance of Text_IO.Float_IO.

17.a

Returns, in the parameter Item, the value of type Complex that corresponds to the input sequence.

18

The exception Text_IO.Data_Error is raised if the input sequence does not have the required syntax or if the components of the complex value obtained are not of the base subtype of Complex_Types.Real.

19

```
procedure Put (File : in File_Type;
               Item : in Complex;
               Fore : in Field := Default_Fore;
               Aft  : in Field := Default_Aft;
               Exp  : in Field := Default_Exp);
procedure Put (Item : in Complex;
               Fore : in Field := Default_Fore;
               Aft  : in Field := Default_Aft;
               Exp  : in Field := Default_Exp);
```

20

21 Outputs the value of the parameter Item as a pair of decimal literals representing the real and imaginary components of the complex value, using the syntax of an aggregate. More specifically,

22 • outputs a left parenthesis;

23 • outputs the value of the real component of the parameter Item with the format defined by the corresponding Put procedure of an instance of Text_IO.Float_IO for the base subtype of Complex_Types.Real, using the given values of Fore, Aft, and Exp;

24 • outputs a comma;

25 • outputs the value of the imaginary component of the parameter Item with the format defined by the corresponding Put procedure of an instance of Text_IO.Float_IO for the base subtype of Complex_Types.Real, using the given values of Fore, Aft, and Exp;

26 • outputs a right parenthesis.

26.a **Discussion:** If the file has a bounded line length, a line terminator may be output implicitly before any element of the sequence itemized above.

26.b **Discussion:** The option of outputting the complex value as a pair of reals without additional punctuation is not provided, since it can be accomplished by outputting the real and imaginary components of the complex value separately.

27
```
procedure Get (From : in  String;
               Item : out Complex;
               Last : out Positive);
```

28/2 {*AI95-00434-01*} Reads a complex value from the beginning of the given string, following the same rule as the Get procedure that reads a complex value from a file, but treating the end of the string as a file terminator. Returns, in the parameter Item, the value of type Complex that corresponds to the input sequence. Returns in Last the index value such that From(Last) is the last character read.

29 The exception Text_IO.Data_Error is raised if the input sequence does not have the required syntax or if the components of the complex value obtained are not of the base subtype of Complex_Types.Real.

30
```
procedure Put (To   : out String;
               Item : in  Complex;
               Aft  : in  Field := Default_Aft;
               Exp  : in  Field := Default_Exp);
```

31 Outputs the value of the parameter Item to the given string as a pair of decimal literals representing the real and imaginary components of the complex value, using the syntax of an aggregate. More specifically,

32 • a left parenthesis, the real component, and a comma are left justified in the given string, with the real component having the format defined by the Put procedure (for output to a file) of an instance of Text_IO.Float_IO for the base subtype of Complex_Types.Real, using a value of zero for Fore and the given values of Aft and Exp;

33 • the imaginary component and a right parenthesis are right justified in the given string, with the imaginary component having the format defined by the Put procedure (for output to a file) of an instance of Text_IO.Float_IO for the base subtype of Complex_Types.Real, using a value for Fore that completely fills the remainder of the string, together with the given values of Aft and Exp.

33.a **Reason:** This rule is the one proposed in LSN-1051. Other rules were considered, including one that would have read "Outputs the value of the parameter Item to the given string, following the same rule as for output to a file, using a value for Fore such that the sequence of characters output exactly fills, or comes closest to filling, the string; in the latter case, the string is filled by inserting one extra blank immediately after the comma." While this latter rule might be considered the closest analogue to the rule for output to a string in Text_IO.Float_IO, it requires a more difficult and

inefficient implementation involving special cases when the integer part of one component is substantially longer than that of the other and the string is too short to allow both to be preceded by blanks. Unless such a special case applies, the latter rule might produce better columnar output if several such strings are ultimately output to a file, but very nearly the same output can be produced by outputting to the file directly, with the appropriate value of Fore; in any case, it might validly be assumed that output to a string is intended for further computation rather than for display, so that the precise formatting of the string to achieve a particular appearance is not the major concern.

The exception Text_IO.Layout_Error is raised if the given string is too short to hold the formatted output. 34

Implementation Permissions

Other exceptions declared (by renaming) in Text_IO may be raised by the preceding procedures in the appropriate circumstances, as for the corresponding procedures of Text_IO.Float_IO. 35

Extensions to Ada 95

{*AI95-00328-01*} Nongeneric equivalents for Text_IO.Complex_IO are added, to be consistent with all other language-defined Numerics generic packages. 35.a/2

Wording Changes from Ada 95

{*8652/0092*} {*AI95-00029-01*} **Corrigendum:** Clarified that the syntax of values read by Complex_IO is the same as that read by Text_IO.Float_IO. 35.b/2

G.1.4 The Package Wide_Text_IO.Complex_IO

Static Semantics

Implementations shall also provide the generic library package Wide_Text_IO.Complex_IO. Its declaration is obtained from that of Text_IO.Complex_IO by systematically replacing Text_IO by Wide_Text_IO and String by Wide_String; the description of its behavior is obtained by additionally replacing references to particular characters (commas, parentheses, etc.) by those for the corresponding wide characters. 1

G.1.5 The Package Wide_Wide_Text_IO.Complex_IO

Static Semantics

{*AI95-00285-01*} Implementations shall also provide the generic library package Wide_Wide_Text_IO.Complex_IO. Its declaration is obtained from that of Text_IO.Complex_IO by systematically replacing Text_IO by Wide_Wide_Text_IO and String by Wide_Wide_String; the description of its behavior is obtained by additionally replacing references to particular characters (commas, parentheses, etc.) by those for the corresponding wide wide characters. 1/2

Extensions to Ada 95

{*AI95-00285-01*} Package Wide_Wide_Text_IO.Complex_IO is new. (At least it wasn't called Incredibly_Wide_Text_IO.Complex_IO; maybe next time.) 1.a/2

G.2 Numeric Performance Requirements

Implementation Requirements

Implementations shall provide a user-selectable mode in which the accuracy and other numeric performance requirements detailed in the following subclauses are observed. This mode, referred to as the *strict mode*, may or may not be the default mode; it directly affects the results of the predefined arithmetic operations of real types and the results of the subprograms in children of the Numerics package, and 1

indirectly affects the operations in other language defined packages. Implementations shall also provide the opposing mode, which is known as the *relaxed mode*.

1.a **Reason:** On the assumption that the users of an implementation that does not support the Numerics Annex have no particular need for numerical performance, such an implementation has no obligation to meet any particular requirements in this area. On the other hand, users of an implementation that does support the Numerics Annex are provided with a way of ensuring that their programs achieve a known level of numerical performance and that the performance is portable to other such implementations. The relaxed mode is provided to allow implementers to offer an efficient but not fully accurate alternative in the case that the strict mode entails a time overhead that some users may find excessive. In some of its areas of impact, the relaxed mode may be fully equivalent to the strict mode.

1.b **Implementation Note:** The relaxed mode may, for example, be used to exploit the implementation of (some of) the elementary functions in hardware, when available. Such implementations often do not meet the accuracy requirements of the strict mode, or do not meet them over the specified range of parameter values, but compensate in other ways that may be important to the user, such as their extreme speed.

1.c **Ramification:** For implementations supporting the Numerics Annex, the choice of mode has no effect on the selection of a representation for a real type or on the values of attributes of a real type.

Implementation Permissions

2 Either mode may be the default mode.

2.a **Implementation defined:** Whether the strict mode or the relaxed mode is the default.

3/5 {*AI12-0444-1*} The two modes can be one and the same.

Extensions to Ada 83

3.a The choice between strict and relaxed numeric performance was not available in Ada 83.

G.2.1 Model of Floating Point Arithmetic

1 In the strict mode, the predefined operations of a floating point type shall satisfy the accuracy requirements specified here and shall avoid or signal overflow in the situations described. This behavior is presented in terms of a model of floating point arithmetic that builds on the concept of the canonical form (see A.5.3).

Static Semantics

2 Associated with each floating point type is an infinite set of model numbers. The model numbers of a type are used to define the accuracy requirements that have to be satisfied by certain predefined operations of the type; through certain attributes of the model numbers, they are also used to explain the meaning of a user-declared floating point type declaration. The model numbers of a derived type are those of the parent type; the model numbers of a subtype are those of its type.

3 The *model numbers* of a floating point type T are zero and all the values expressible in the canonical form (for the type T), in which *mantissa* has T'Model_Mantissa digits and *exponent* has a value greater than or equal to T'Model_Emin. (These attributes are defined in G.2.2.)

3.a **Discussion:** The model is capable of describing the behavior of most existing hardware that has a mantissa-exponent representation. As applied to a type T, it is parameterized by the values of T'Machine_Radix, T'Model_Mantissa, T'Model_Emin, T'Safe_First, and T'Safe_Last. The values of these attributes are determined by how, and how well, the hardware behaves. They in turn determine the set of model numbers and the safe range of the type, which figure in the accuracy and range (overflow avoidance) requirements.

3.b/5 {*AI12-0453-1*} In hardware that is free of arithmetic anomalies, T'Model_Mantissa, T'Model_Emin, T'Safe_First, and T'Safe_Last will yield the same values as T'Machine_Mantissa, T'Machine_Emin, T'Base'First, and T'Base'Last, respectively, and the model numbers in the safe range of the type T will coincide with the machine numbers of the type T. In less perfect hardware, it is not possible for the model-oriented attributes to have these optimal values, since the hardware, by definition, and therefore the implementation, cannot conform to the stringencies of the resulting model; in this case, the values yielded by the model-oriented parameters have to be made more conservative (that is, have to be penalized), with the result that the model numbers are more widely separated than the machine numbers, and the

safe range is a subrange of the base range. The implementation will then be able to conform to the requirements of the weaker model defined by the sparser set of model numbers and the smaller safe range.

A *model interval* of a floating point type is any interval whose bounds are model numbers of the type. The *model interval* of a type T *associated with a value v* is the smallest model interval of T that includes *v*. (The model interval associated with a model number of a type consists of that number only.) 4

Implementation Requirements

The accuracy requirements for the evaluation of certain predefined operations of floating point types are as follows. 5

Discussion: This subclause does not cover the accuracy of an operation of a static expression; such operations have to be evaluated exactly (see 4.9). It also does not cover the accuracy of the predefined attributes of a floating point subtype that yield a value of the type; such operations also yield exact results (see 3.5.8 and A.5.3). 5.a

An *operand interval* is the model interval, of the type specified for the operand of an operation, associated with the value of the operand. 6

For any predefined arithmetic operation that yields a result of a floating point type T, the required bounds on the result are given by a model interval of T (called the *result interval*) defined in terms of the operand values as follows: 7

- The result interval is the smallest model interval of T that includes the minimum and the maximum of all the values obtained by applying the (exact) mathematical operation to values arbitrarily selected from the respective operand intervals. 8

The result interval of an exponentiation is obtained by applying the above rule to the sequence of multiplications defined by the exponent, assuming arbitrary association of the factors, and to the final division in the case of a negative exponent. 9

The result interval of a conversion of a numeric value to a floating point type T is the model interval of T associated with the operand value, except when the source expression is of a fixed point type with a *small* that is not a power of T'Machine_Radix or is a fixed point multiplication or division either of whose operands has a *small* that is not a power of T'Machine_Radix; in these cases, the result interval is implementation defined. 10

Implementation defined: The result interval in certain cases of fixed-to-float conversion. 10.a

For any of the foregoing operations, the implementation shall deliver a value that belongs to the result interval when both bounds of the result interval are in the safe range of the result type T, as determined by the values of T'Safe_First and T'Safe_Last; otherwise, 11

- if T'Machine_Overflows is True, the implementation shall either deliver a value that belongs to the result interval or raise Constraint_Error; 12
- if T'Machine_Overflows is False, the result is implementation defined. 13

Implementation defined: The result of a floating point arithmetic operation in overflow situations, when the Machine_Overflows attribute of the result type is False. 13.a

{*AI12-0453-1*} For any predefined relation on operands of a floating point type T, the implementation may deliver any value (that is, either True or False) obtained by applying the (exact) mathematical comparison to values arbitrarily chosen from the respective operand intervals. 14/5

The result of a membership test is defined in terms of comparisons of the operand value with the lower and upper bounds of the given range or type mark (the usual rules apply to these comparisons). 15

Implementation Permissions

If the underlying floating point hardware implements division as multiplication by a reciprocal, the result interval for division (and exponentiation by a negative exponent) is implementation defined. 16

16.a **Implementation defined:** The result interval for division (or exponentiation by a negative exponent), when the floating point hardware implements division as multiplication by a reciprocal.

Wording Changes from Ada 83

16.b The Ada 95 model numbers of a floating point type that are in the safe range of the type are comparable to the Ada 83 safe numbers of the type. There is no analog of the Ada 83 model numbers. The Ada 95 model numbers, when not restricted to the safe range, are an infinite set.

Inconsistencies With Ada 83

16.c Giving the model numbers the hardware radix, instead of always a radix of two, allows (in conjunction with other changes) some borderline declared types to be represented with less precision than in Ada 83 (that is, with single precision, whereas Ada 83 would have used double precision). Because the lower precision satisfies the requirements of the model (and did so in Ada 83 as well), this change is viewed as a desirable correction of an anomaly, rather than a worrisome inconsistency. (Of course, the wider representation chosen in Ada 83 also remains eligible for selection in Ada 95.)

16.d/5 {*AI12-0453-1*} As an example of this phenomenon, assume that Float is represented in single precision and that a double precision type is also available. Also assume hexadecimal hardware with clean properties, for example certain IBM hardware. Then,

16.e
```
type T is digits Float'Digits range -Float'Last .. Float'Last;
```

16.f results in T being represented in double precision in Ada 83 and in single precision in Ada 95. The latter is intuitively correct; the former is counterintuitive. The reason why the double precision type is used in Ada 83 is that Float has model and safe numbers (in Ada 83) with 21 binary digits in their mantissas, as is required to model the hypothesized hexadecimal hardware using a binary radix; thus Float'Last, which is not a model number, is slightly outside the range of safe numbers of the single precision type, making that type ineligible for selection as the representation of T even though it provides adequate precision. In Ada 95, Float'Last (the same value as before) is a model number and is in the safe range of Float on the hypothesized hardware, making Float eligible for the representation of T.

Extensions to Ada 83

16.g Giving the model numbers the hardware radix allows for practical implementations on decimal hardware.

Wording Changes from Ada 83

16.h The wording of the model of floating point arithmetic has been simplified to a large extent.

G.2.2 Model-Oriented Attributes of Floating Point Types

1 In implementations that support the Numerics Annex, the model-oriented attributes of floating point types shall yield the values defined here, in both the strict and the relaxed modes. These definitions add conditions to those in A.5.3.

Static Semantics

2 For every subtype S of a floating point type *T*:

3/2 {*AI95-00256-01*} S'Model_Mantissa

Yields the number of digits in the mantissa of the canonical form of the model numbers of *T* (see A.5.3). The value of this attribute shall be greater than or equal to

3.1/2 $\lceil d \cdot \log(10) / \log(T\text{'Machine\_Radix}) \rceil + g$

3.2/2 where *d* is the requested decimal precision of *T*, and *g* is 0 if *T*'Machine_Radix is a positive power of 10 and 1 otherwise. In addition, *T*'Model_Mantissa shall be less than or equal to the value of *T*'Machine_Mantissa. This attribute yields a value of the type *universal_integer*.

3.a **Ramification:** S'Model_Epsilon, which is defined in terms of S'Model_Mantissa (see A.5.3), yields the absolute value of the difference between one and the next model number of the type *T* above one. It is equal to or larger than the absolute value of the difference between one and the next machine number of the type *T* above one.

S'Model_Emin 4

Yields the minimum exponent of the canonical form of the model numbers of *T* (see A.5.3). The value of this attribute shall be greater than or equal to the value of *T*'Machine_Emin. This attribute yields a value of the type *universal_integer*.

Ramification: S'Model_Small, which is defined in terms of S'Model_Emin (see A.5.3), yields the smallest positive (nonzero) model number of the type *T*. 4.a

S'Safe_First 5

Yields the lower bound of the safe range of *T*. The value of this attribute shall be a model number of *T* and greater than or equal to the lower bound of the base range of *T*. In addition, if *T* is declared by a floating_point_definition or is derived from such a type, and the floating_point_definition includes a real_range_specification specifying a lower bound of *lb*, then the value of this attribute shall be less than or equal to *lb*; otherwise, it shall be less than or equal to $-10.0^{4 \cdot d}$, where *d* is the requested decimal precision of *T*. This attribute yields a value of the type *universal_real*.

S'Safe_Last 6

Yields the upper bound of the safe range of *T*. The value of this attribute shall be a model number of *T* and less than or equal to the upper bound of the base range of *T*. In addition, if *T* is declared by a floating_point_definition or is derived from such a type, and the floating_point_definition includes a real_range_specification specifying an upper bound of *ub*, then the value of this attribute shall be greater than or equal to *ub*; otherwise, it shall be greater than or equal to $10.0^{4 \cdot d}$, where d is the requested decimal precision of *T*. This attribute yields a value of the type *universal_real*.

S'Model Denotes a function (of a parameter *X*) whose specification is given in A.5.3. If *X* is a model number of *T*, the function yields *X*; otherwise, it yields the value obtained by rounding or truncating *X* to either one of the adjacent model numbers of *T*. Constraint_Error is raised if the resulting model number is outside the safe range of S. A zero result has the sign of *X* when S'Signed_Zeros is True. 7

Subject to the constraints given above, the values of S'Model_Mantissa and S'Safe_Last are to be maximized, and the values of S'Model_Emin and S'Safe_First minimized, by the implementation as follows: 8

- First, S'Model_Mantissa is set to the largest value for which values of S'Model_Emin, S'Safe_First, and S'Safe_Last can be chosen so that the implementation satisfies the strict-mode requirements of G.2.1 in terms of the model numbers and safe range induced by these attributes. 9
- Next, S'Model_Emin is set to the smallest value for which values of S'Safe_First and S'Safe_Last can be chosen so that the implementation satisfies the strict-mode requirements of G.2.1 in terms of the model numbers and safe range induced by these attributes and the previously determined value of S'Model_Mantissa. 10
- {*AI05-0092-1*} Finally, S'Safe_First and S'Safe_Last are set (in either order) to the smallest and largest values, respectively, for which the implementation satisfies the strict-mode requirements of G.2.1 in terms of the model numbers and safe range induced by these attributes and the previously determined values of S'Model_Mantissa and S'Model_Emin. 11/3

Ramification: {*AI12-0437-1*} The following table shows appropriate attribute values for IEEE basic single and double precision types (ANSI/IEEE Std 754-1985, ISO/IEC 60559:2020). Here, we use the names IEEE_Float_32 and IEEE_Float_64, the names that would typically be declared in package Interfaces, in an implementation that supports IEEE arithmetic. In such an implementation, the attributes would typically be the same for Standard.Float and Long_Float, respectively. 11.a/5

Attribute	IEEE_Float_32	IEEE_Float_64	11.b

11.c

'Machine_Radix	2	2
'Machine_Mantissa	24	53
'Machine_Emin	-125	-1021
'Machine_Emax	128	1024
'Denorm	True	True
'Machine_Rounds	True	True
'Machine_Overflows	True/False	True/False
'Signed_Zeros	should be True	should be True

11.d

'Model_Mantissa	(same as 'Machine_Mantissa)	(same as 'Machine_Mantissa)
'Model_Emin	(same as 'Machine_Emin)	(same as 'Machine_Emin)
'Model_Epsilon	2.0**(-23)	2.0**(-52)
'Model_Small	2.0**(-126)	2.0**(-1022)
'Safe_First	-2.0**128*(1.0-2.0**(-24))	-2.0**1024*(1.0-2.0**(-53))
'Safe_Last	2.0**128*(1.0-2.0**(-24))	2.0**1024*(1.0-2.0**(-53))

11.e

'Digits	6	15
'Base'Digits	(same as 'Digits)	(same as 'Digits)

11.f

'First	(same as 'Safe_First)	(same as 'Safe_First)
'Last	(same as 'Safe_Last)	(same as 'Safe_Last)
'Size	32	64

11.g Note: 'Machine_Overflows can be True or False, depending on whether the Ada implementation raises Constraint_Error or delivers a signed infinity in overflow and zerodivide situations (and at poles of the elementary functions).

Wording Changes from Ada 95

11.h/2 {*AI95-00256-01*} Corrected the definition of Model_Mantissa to match that given in 3.5.8.

G.2.3 Model of Fixed Point Arithmetic

1 In the strict mode, the predefined arithmetic operations of a fixed point type shall satisfy the accuracy requirements specified here and shall avoid or signal overflow in the situations described.

Implementation Requirements

2 The accuracy requirements for the predefined fixed point arithmetic operations and conversions, and the results of relations on fixed point operands, are given below.

2.a **Discussion:** This subclause does not cover the accuracy of an operation of a static expression; such operations have to be evaluated exactly (see 4.9).

3 The operands of the fixed point adding operators, absolute value, and comparisons have the same type. These operations are required to yield exact results, unless they overflow.

4 Multiplications and divisions are allowed between operands of any two fixed point types; the result has to be (implicitly or explicitly) converted to some other numeric type. For purposes of defining the accuracy rules, the multiplication or division and the conversion are treated as a single operation whose accuracy depends on three types (those of the operands and the result). For decimal fixed point types, the attribute T'Round may be used to imply explicit conversion with rounding (see 3.5.10).

5 When the result type is a floating point type, the accuracy is as given in G.2.1. For some combinations of the operand and result types in the remaining cases, the result is required to belong to a small set of values called the *perfect result set*; for other combinations, it is required merely to belong to a generally larger and implementation-defined set of values called the *close result set*. When the result type is a decimal fixed point type, the perfect result set contains a single value; thus, operations on decimal types are always fully specified.

5.a **Implementation defined:** The definition of *close result set*, which determines the accuracy of certain fixed point multiplications and divisions.

6/5 {*AI12-0453-1*} When one operand of a fixed-fixed multiplication or division is of type *universal_real*, that operand is not implicitly converted in the usual sense, since the context does not determine a unique target type, but the accuracy of the result of the multiplication or division (that is, whether the result has

to belong to the perfect result set or merely the close result set) depends on the value of the operand of type *universal_real* and on the types of the other operand and of the result.

Discussion: {*AI12-0453-1*} We need not consider here the multiplication or division of two such operands, since in that case either the operation is evaluated exactly (that is, it is an operation of a static expression all of whose operators are of a root numeric type) or it is considered to be an operation of a floating point type. 6.a/5

For a fixed point multiplication or division whose (exact) mathematical result is *v*, and for the conversion of a value *v* to a fixed point type, the perfect result set and close result set are defined as follows: 7

- If the result type is an ordinary fixed point type with a *small* of *s*, 8
  - if *v* is an integer multiple of *s*, then the perfect result set contains only the value *v*; 9
  - otherwise, it contains the integer multiple of *s* just below *v* and the integer multiple of *s* just above *v*. 10

  The close result set is an implementation-defined set of consecutive integer multiples of *s* containing the perfect result set as a subset. 11
- If the result type is a decimal type with a *small* of *s*, 12
  - if *v* is an integer multiple of *s*, then the perfect result set contains only the value *v*; 13
  - {*AI05-0264-1*} otherwise, if truncation applies, then it contains only the integer multiple of *s* in the direction toward zero, whereas if rounding applies, then it contains only the nearest integer multiple of *s* (with ties broken by rounding away from zero). 14/3

  The close result set is an implementation-defined set of consecutive integer multiples of *s* containing the perfect result set as a subset. 15

  Ramification: As a consequence of subsequent rules, this case does not arise when the operand types are also decimal types. 15.a
- If the result type is an integer type, 16
  - if *v* is an integer, then the perfect result set contains only the value *v*; 17
  - otherwise, it contains the integer nearest to the value *v* (if *v* lies equally distant from two consecutive integers, the perfect result set contains the one that is further from zero). 18

  The close result set is an implementation-defined set of consecutive integers containing the perfect result set as a subset. 19

{*AI12-0453-1*} The result of a fixed point multiplication or division shall belong either to the perfect result set or to the close result set, as described below, if overflow does not occur. In the following cases, if the result type is a fixed point type, let *s* be its *small*; otherwise, that is when the result type is an integer type, let *s* be 1.0. 20/5

- {*AI12-0453-1*} For a multiplication or division neither of whose operands is of type *universal_real*, let *l* and *r* be the *smalls* of the left and right operands. For a multiplication, if $(l \cdot r) / s$ is an integer or the reciprocal of an integer (the *smalls* are said to be "compatible" in this case), the result shall belong to the perfect result set; otherwise, it belongs to the close result set. For a division, if $l / (r \cdot s)$ is an integer or the reciprocal of an integer (that is, the *smalls* are compatible), the result shall belong to the perfect result set; otherwise, it belongs to the close result set. 21/5

  Ramification: When the operand and result types are all decimal types, their *smalls* are necessarily compatible; the same is true when they are all ordinary fixed point types with binary *smalls*. 21.a
- For a multiplication or division having one *universal_real* operand with a value of *v*, note that it is always possible to factor *v* as an integer multiple of a "compatible" *small*, but the integer multiple may be "too big". If there exists a factorization in which that multiple is less than some implementation-defined limit, the result shall belong to the perfect result set; otherwise, it belongs to the close result set. 22

22.a **Implementation defined:** Conditions on a *universal_real* operand of a fixed point multiplication or division for which the result shall be in the *perfect result set*.

23/5 {*AI12-0300-1*} A multiplication P * Q of an operand of a fixed point type F by an operand of type Integer, or vice versa, and a division P / Q of an operand of a fixed point type F by an operand of type Integer, are also allowed. In these cases, the result has the type of F; explicit conversion of the result is never required. The accuracy required in these cases is the same as that required for a multiplication F(P * Q) or a division F(P / Q) obtained by interpreting the operand of the integer type to have a fixed point type with a *small* of 1.0.

24 The accuracy of the result of a conversion from an integer or fixed point type to a fixed point type, or from a fixed point type to an integer type, is the same as that of a fixed point multiplication of the source value by a fixed point operand having a *small* of 1.0 and a value of 1.0, as given by the foregoing rules. The result of a conversion from a floating point type to a fixed point type shall belong to the close result set. The result of a conversion of a *universal_real* operand to a fixed point type shall belong to the perfect result set.

25 The possibility of overflow in the result of a predefined arithmetic operation or conversion yielding a result of a fixed point type T is analogous to that for floating point types, except for being related to the base range instead of the safe range. If all of the permitted results belong to the base range of T, then the implementation shall deliver one of the permitted results; otherwise,

26 • if T'Machine_Overflows is True, the implementation shall either deliver one of the permitted results or raise Constraint_Error;

27 • if T'Machine_Overflows is False, the result is implementation defined.

27.a **Implementation defined:** The result of a fixed point arithmetic operation in overflow situations, when the Machine_Overflows attribute of the result type is False.

Inconsistencies With Ada 83

27.b Since the values of a fixed point type are now just the integer multiples of its *small*, the possibility of using extra bits available in the chosen representation for extra accuracy rather than for increasing the base range would appear to be removed, raising the possibility that some fixed point expressions will yield less accurate results than in Ada 83. However, this is partially offset by the ability of an implementation to choose a smaller default *small* than before. Of course, if it does so for a type T then T'Small will have a different value than it previously had.

27.c The accuracy requirements in the case of incompatible *smalls* are relaxed to foster wider support for nonbinary *smalls*. If this relaxation is exploited for a type that was previously supported, lower accuracy could result; however, there is no particular incentive to exploit the relaxation in such a case.

Wording Changes from Ada 83

27.d The fixed point accuracy requirements are now expressed without reference to model or safe numbers, largely because the full generality of the former model was never exploited in the case of fixed point types (particularly in regard to operand perturbation). Although the new formulation in terms of perfect result sets and close result sets is still verbose, it can be seen to distill down to two cases:

27.e • a case where the result must be the exact result, if the exact result is representable, or, if not, then either one of the adjacent values of the type (in some subcases only one of those adjacent values is allowed);

27.f • a case where the accuracy is not specified by the language.

Wording Changes from Ada 2012

27.g/5 {*AI12-0300-1*} **Correction:** Reworded the fixed*integer accuracy requirements to clarify that the only allowed integer type in such operations is Standard.Integer. We make this correction as readers of the Reference Manual have been confused on this point.

G.2.4 Accuracy Requirements for the Elementary Functions

In the strict mode, the performance of Numerics.Generic_Elementary_Functions shall be as specified here. 1

Implementation Requirements

When an exception is not raised, the result of evaluating a function in an instance *EF* of Numerics.Generic_Elementary_Functions belongs to a *result interval*, defined as the smallest model interval of *EF*.Float_Type that contains all the values of the form $f \cdot (1.0 + d)$, where f is the exact value of the corresponding mathematical function at the given parameter values, d is a real number, and $|d|$ is less than or equal to the function's *maximum relative error*. The function delivers a value that belongs to the result interval when both of its bounds belong to the safe range of *EF*.Float_Type; otherwise, 2

- if *EF*.Float_Type'Machine_Overflows is True, the function either delivers a value that belongs to the result interval or raises Constraint_Error, signaling overflow; 3
- if *EF*.Float_Type'Machine_Overflows is False, the result is implementation defined. 4

  Implementation defined: The result of an elementary function reference in overflow situations, when the Machine_Overflows attribute of the result type is False. 4.a

The maximum relative error exhibited by each function is as follows: 5

- $2.0 \cdot$ *EF*.Float_Type'Model_Epsilon, in the case of the Sqrt, Sin, and Cos functions; 6
- $4.0 \cdot$ *EF*.Float_Type'Model_Epsilon, in the case of the Log, Exp, Tan, Cot, and inverse trigonometric functions; and 7
- $8.0 \cdot$ *EF*.Float_Type'Model_Epsilon, in the case of the forward and inverse hyperbolic functions. 8

The maximum relative error exhibited by the exponentiation operator, which depends on the values of the operands, is $(4.0 + |\text{Right} \cdot \log(\text{Left})| / 32.0) \cdot$ *EF*.Float_Type'Model_Epsilon. 9

The maximum relative error given above applies throughout the domain of the forward trigonometric functions when the Cycle parameter is specified. When the Cycle parameter is omitted, the maximum relative error given above applies only when the absolute value of the angle parameter X is less than or equal to some implementation-defined *angle threshold*, which shall be at least *EF*.Float_Type'Machine_Radix $^{\lfloor EF.\text{Float\_Type'Machine\_Mantissa}/2 \rfloor}$. Beyond the angle threshold, the accuracy of the forward trigonometric functions is implementation defined. 10

Implementation defined: The value of the *angle threshold*, within which certain elementary functions, complex arithmetic operations, and complex elementary functions yield results conforming to a maximum relative error bound. 10.a

Implementation defined: The accuracy of certain elementary functions for parameters beyond the angle threshold. 10.b

Implementation Note: The angle threshold indirectly determines the amount of precision that the implementation has to maintain during argument reduction. 10.c

{*AI95-00434-01*} {*AI12-0451-1*} The prescribed results specified in A.5.1 for certain functions at particular parameter values take precedence over the maximum relative error bounds; effectively, they narrow to a single value the result interval allowed by the maximum relative error bounds. Additional rules with a similar effect are given by Table G.1 for the inverse trigonometric functions, at particular parameter values for which the mathematical result is possibly not a model number of *EF*.Float_Type (or is, indeed, even transcendental). In each table entry, the values of the parameters are such that the result lies on the axis between two quadrants; the corresponding accuracy rule, which takes precedence over the maximum relative error bounds, is that the result interval is the model interval of *EF*.Float_Type associated with the exact mathematical result given in the table. 11/5

This paragraph was deleted. 12/1

13 The last line of the table is meant to apply when *EF*.Float_Type'Signed_Zeros is False; the two lines just above it, when *EF*.Float_Type'Signed_Zeros is True and the parameter Y has a zero value with the indicated sign.

Table G.1: Tightly Approximated Elementary Function Results

Function	Value of X	Value of Y	Exact Result when Cycle Specified	Exact Result when Cycle Omitted
Arcsin	1.0	n.a.	Cycle/4.0	π/2.0
Arcsin	–1.0	n.a.	–Cycle/4.0	–π/2.0
Arccos	0.0	n.a.	Cycle/4.0	π/2.0
Arccos	–1.0	n.a.	Cycle/2.0	π
Arctan and Arccot	0.0	positive	Cycle/4.0	π/2.0
Arctan and Arccot	0.0	negative	–Cycle/4.0	–π/2.0
Arctan and Arccot	negative	+0.0	Cycle/2.0	π
Arctan and Arccot	negative	–0.0	–Cycle/2.0	–π
Arctan and Arccot	negative	0.0	Cycle/2.0	π

14 The amount by which the result of an inverse trigonometric function is allowed to spill over into a quadrant adjacent to the one corresponding to the principal branch, as given in A.5.1, is limited. The rule is that the result belongs to the smallest model interval of *EF*.Float_Type that contains both boundaries of the quadrant corresponding to the principal branch. This rule also takes precedence over the maximum relative error bounds, effectively narrowing the result interval allowed by them.

15 Finally, the following specifications also take precedence over the maximum relative error bounds:

16 • The absolute value of the result of the Sin, Cos, and Tanh functions never exceeds one.

17 • The absolute value of the result of the Coth function is never less than one.

18 • The result of the Cosh function is never less than one.

Implementation Advice

19 The versions of the forward trigonometric functions without a Cycle parameter should not be implemented by calling the corresponding version with a Cycle parameter of 2.0*Numerics.Pi, since this will not provide the required accuracy in some portions of the domain. For the same reason, the version of Log without a Base parameter should not be implemented by calling the corresponding version with a Base parameter of Numerics.e.

19.a.1/2 **Implementation Advice:** For elementary functions, the forward trigonometric functions without a Cycle parameter should not be implemented by calling the corresponding version with a Cycle parameter. Log without a Base parameter should not be implemented by calling Log with a Base parameter.

Wording Changes from Ada 83

19.a The semantics of Numerics.Generic_Elementary_Functions differs from Generic_Elementary_Functions as defined in ISO/IEC DIS 11430 (for Ada 83) in the following ways related to the accuracy specified for strict mode:

19.b • The maximum relative error bounds use the Model_Epsilon attribute instead of the Base'Epsilon attribute.

- The accuracy requirements are expressed in terms of result intervals that are model intervals. On the one hand, this facilitates the description of the required results in the presence of underflow; on the other hand, it slightly relaxes the requirements expressed in ISO/IEC DIS 11430. 19.c

G.2.5 Performance Requirements for Random Number Generation

In the strict mode, the performance of Numerics.Float_Random and Numerics.Discrete_Random shall be as specified here. 1

Implementation Requirements

Two different calls to the time-dependent Reset procedure shall reset the generator to different states, provided that the calls are separated in time by at least one second and not more than fifty years. 2

The implementation's representations of generator states and its algorithms for generating random numbers shall yield a period of at least $2^{31}-2$; much longer periods are desirable but not required. 3

{*AI12-0453-1*} The implementations of Numerics.Float_Random.Random and Numerics.Discrete_Random.Random shall pass at least 85% of the individual trials in a suite of statistical tests. For Numerics.Float_Random, the tests are applied directly to the floating point values generated (that is, they are not converted to integers first), while for Numerics.Discrete_Random they are applied to the generated values of various discrete types. Each test suite performs 6 different tests, with each test repeated 10 times, yielding a total of 60 individual trials. An individual trial is deemed to pass if the chi-square value (or other statistic) calculated for the observed counts or distribution falls within the range of values corresponding to the 2.5 and 97.5 percentage points for the relevant degrees of freedom (that is, it shall be neither too high nor too low). For the purpose of determining the degrees of freedom, measurement categories are combined whenever the expected counts are fewer than 5. 4/5

Implementation Note: In the floating point random number test suite, the generator is reset to a time-dependent state at the beginning of the run. The test suite incorporates the following tests, adapted from D. E. Knuth, *The Art of Computer Programming, vol. 2: Seminumerical Algorithms.* In the descriptions below, the given number of degrees of freedom is the number before reduction due to any necessary combination of measurement categories with small expected counts; it is one less than the number of measurement categories. 4.a

- Proportional Distribution Test (a variant of the Equidistribution Test). The interval 0.0 .. 1.0 is partitioned into K subintervals. K is chosen randomly between 4 and 25 for each repetition of the test, along with the boundaries of the subintervals (subject to the constraint that at least 2 of the subintervals have a width of 0.001 or more). 5000 random floating point numbers are generated. The counts of random numbers falling into each subinterval are tallied and compared with the expected counts, which are proportional to the widths of the subintervals. The number of degrees of freedom for the chi-square test is K–1. 4.b
- Gap Test. The bounds of a range A .. B, with $0.0 \le A < B \le 1.0$, are chosen randomly for each repetition of the test, subject to the constraint that $0.2 \le B-A \le 0.6$. Random floating point numbers are generated until 5000 falling into the range A .. B have been encountered. Each of these 5000 is preceded by a "gap" (of length greater than or equal to 0) of consecutive random numbers not falling into the range A .. B. The counts of gaps of each length from 0 to 15, and of all lengths greater than 15 lumped together, are tallied and compared with the expected counts. Let $P = B-A$. The probability that a gap has a length of L is $(1-P)^{L} \cdot P$ for $L \le 15$, while the probability that a gap has a length of 16 or more is $(1-P)^{16}$. The number of degrees of freedom for the chi-square test is 16. 4.c
- Permutation Test. 5000 tuples of 4 different random floating point numbers are generated. (An entire 4-tuple is discarded in the unlikely event that it contains any two exactly equal components.) The counts of each of the 4! = 24 possible relative orderings of the components of the 4-tuples are tallied and compared with the expected counts. Each of the possible relative orderings has an equal probability. The number of degrees of freedom for the chi-square test is 23. 4.d
- Increasing-Runs Test. Random floating point numbers are generated until 5000 increasing runs have been observed. An "increasing run" is a sequence of random numbers in strictly increasing order; it is followed by a random number that is strictly smaller than the preceding random number. (A run under construction is entirely discarded in the unlikely event that one random number is followed immediately by an exactly equal random number.) The decreasing random number that follows an increasing run is discarded and not included with the next increasing run. The counts of increasing runs of each length from 1 to 4, and of all lengths greater than 4 lumped together, are tallied and compared with the expected counts. The probability 4.e

that an increasing run has a length of L is $1/L! - 1/(L+1)!$ for $L \leq 4$, while the probability that an increasing run has a length of 5 or more is 1/5!. The number of degrees of freedom for the chi-square test is 4.

4.f
- Decreasing-Runs Test. The test is similar to the Increasing Runs Test, but with decreasing runs.

4.g
- Maximum-of-t Test (with $t = 5$). 5000 tuples of 5 random floating point numbers are generated. The maximum of the components of each 5-tuple is determined and raised to the 5th power. The uniformity of the resulting values over the range 0.0 .. 1.0 is tested as in the Proportional Distribution Test.

4.h
Implementation Note: In the discrete random number test suite, Numerics.Discrete_Random is instantiated as described below. The generator is reset to a time-dependent state after each instantiation. The test suite incorporates the following tests, adapted from D. E. Knuth (*op. cit.*) and other sources. The given number of degrees of freedom for the chi-square test is reduced by any necessary combination of measurement categories with small expected counts, as described above.

4.i
- Equidistribution Test. In each repetition of the test, a number R between 2 and 30 is chosen randomly, and Numerics.Discrete_Random is instantiated with an integer subtype whose range is 1 .. R. 5000 integers are generated randomly from this range. The counts of occurrences of each integer in the range are tallied and compared with the expected counts, which have equal probabilities. The number of degrees of freedom for the chi-square test is R–1.

4.j
- Simplified Poker Test. Numerics.Discrete_Random is instantiated once with an enumeration subtype representing the 13 denominations (Two through Ten, Jack, Queen, King, and Ace) of an infinite deck of playing cards. 2000 “poker” hands (5-tuples of values of this subtype) are generated randomly. The counts of hands containing exactly K different denominations ($1 \leq K \leq 5$) are tallied and compared with the expected counts. The probability that a hand contains exactly K different denominations is given by a formula in Knuth. The number of degrees of freedom for the chi-square test is 4.

4.k
- Coupon Collector's Test. Numerics.Discrete_Random is instantiated in each repetition of the test with an integer subtype whose range is 1 .. R, where R varies systematically from 2 to 11. Integers are generated randomly from this range until each value in the range has occurred, and the number K of integers generated is recorded. This constitutes a “coupon collector's segment” of length K. 2000 such segments are generated. The counts of segments of each length from R to R+29, and of all lengths greater than R+29 lumped together, are tallied and compared with the expected counts. The probability that a segment has any given length is given by formulas in Knuth. The number of degrees of freedom for the chi-square test is 30.

4.l
- Craps Test (Lengths of Games). Numerics.Discrete_Random is instantiated once with an integer subtype whose range is 1 .. 6 (representing the six numbers on a die). 5000 craps games are played, and their lengths are recorded. (The length of a craps game is the number of rolls of the pair of dice required to produce a win or a loss. A game is won on the first roll if the dice show 7 or 11; it is lost if they show 2, 3, or 12. If the dice show some other sum on the first roll, it is called the *point*, and the game is won if and only if the point is rolled again before a 7 is rolled.) The counts of games of each length from 1 to 18, and of all lengths greater than 18 lumped together, are tallied and compared with the expected counts. For $2 \leq S \leq 12$, let D_S be the probability that a roll of a pair of dice shows the sum S, and let $Q_S(L) = D_S \cdot (1 - (D_S + D_7))^{L-2} \cdot (D_S + D_7)$. Then, the probability that a game has a length of 1 is $D_7 + D_{11} + D_2 + D_3 + D_{12}$ and, for $L > 1$, the probability that a game has a length of L is $Q_4(L) + Q_5(L) + Q_6(L) + Q_8(L) + Q_9(L) + Q_{10}(L)$. The number of degrees of freedom for the chi-square test is 18.

4.m
- Craps Test (Lengths of Passes). This test is similar to the last, but enough craps games are played for 3000 losses to occur. A string of wins followed by a loss is called a *pass*, and its length is the number of wins preceding the loss. The counts of passes of each length from 0 to 7, and of all lengths greater than 7 lumped together, are tallied and compared with the expected counts. For $L \geq 0$, the probability that a pass has a length of L is $W^L \cdot (1-W)$, where W, the probability that a game ends in a win, is 244.0/495.0. The number of degrees of freedom for the chi-square test is 8.

4.n
- Collision Test. Numerics.Discrete_Random is instantiated once with an integer or enumeration type representing binary bits. 15 successive calls on the Random function are used to obtain the bits of a 15-bit binary integer between 0 and 32767. 3000 such integers are generated, and the number of collisions (integers previously generated) is counted and compared with the expected count. A chi-square test is not used to assess the number of collisions; rather, the limits on the number of collisions, corresponding to the 2.5 and 97.5 percentage points, are (from formulas in Knuth) 112 and 154. The test passes if and only if the number of collisions is in this range.

G.2.6 Accuracy Requirements for Complex Arithmetic

1 In the strict mode, the performance of Numerics.Generic_Complex_Types and Numerics.Generic_-Complex_Elementary_Functions shall be as specified here.

Implementation Requirements

{*AI12-0453-1*} When an exception is not raised, the result of evaluating a real function of an instance *CT* of Numerics.Generic_Complex_Types (that is, a function that yields a value of subtype *CT*.Real'Base or *CT*.Imaginary) belongs to a result interval defined as for a real elementary function (see G.2.4). 2/5

{*AI12-0453-1*} When an exception is not raised, each component of the result of evaluating a complex function of such an instance, or of an instance of Numerics.Generic_Complex_Elementary_Functions obtained by instantiating the latter with *CT* (that is, a function that yields a value of subtype *CT*.Complex), also belongs to a *result interval*. The result intervals for the components of the result are either defined by a *maximum relative error* bound or by a *maximum box error* bound. When the result interval for the real (resp., imaginary) component is defined by maximum relative error, it is defined as for that of a real function, relative to the exact value of the real (resp., imaginary) part of the result of the corresponding mathematical function. When defined by maximum box error, the result interval for a component of the result is the smallest model interval of *CT*.Real that contains all the values of the corresponding part of $f \cdot (1.0 + d)$, where f is the exact complex value of the corresponding mathematical function at the given parameter values, d is complex, and $|d|$ is less than or equal to the given maximum box error. The function delivers a value that belongs to the result interval (or a value both of whose components belong to their respective result intervals) when both bounds of the result interval(s) belong to the safe range of *CT*.Real; otherwise, 3/5

Discussion: The maximum relative error could be specified separately for each component, but we do not take advantage of that freedom here. 3.a

Discussion: Note that $f \cdot (1.0 + d)$ defines a small circular region of the complex plane centered at f, and the result intervals for the real and imaginary components of the result define a small rectangular box containing that circle. 3.b

Reason: Box error is used when the computation of the result risks loss of significance in a component due to cancellation. 3.c

Ramification: The components of a complex function that exhibits bounded relative error in each component have to have the correct sign. In contrast, one of the components of a complex function that exhibits bounded box error may have the wrong sign, since the dimensions of the box containing the result are proportional to the modulus of the mathematical result and not to either component of the mathematical result individually. Thus, for example, the box containing the computed result of a complex function whose mathematical result has a large modulus but lies very close to the imaginary axis might well straddle that axis, allowing the real component of the computed result to have the wrong sign. In this case, the distance between the computed result and the mathematical result is, nevertheless, a small fraction of the modulus of the mathematical result. 3.d

- if *CT*.Real'Machine_Overflows is True, the function either delivers a value that belongs to the result interval (or a value both of whose components belong to their respective result intervals) or raises Constraint_Error, signaling overflow; 4
- if *CT*.Real'Machine_Overflows is False, the result is implementation defined. 5

Implementation defined: The result of a complex arithmetic operation or complex elementary function reference in overflow situations, when the Machine_Overflows attribute of the corresponding real type is False. 5.a

{*AI95-00434-01*} The error bounds for particular complex functions are tabulated in Table G.2. In the table, the error bound is given as the coefficient of *CT*.Real'Model_Epsilon. 6/2

This paragraph was deleted. 7/1

Table G.2: Error Bounds for Particular Complex Functions

Function or Operator	Nature of Result	Nature of Bound	Error Bound
Modulus	real	max. rel. error	3.0
Argument	real	max. rel. error	4.0

Compose_From_Polar	complex	max. rel. error	3.0
"*" (both operands complex)	complex	max. box error	5.0
"/" (right operand complex)	complex	max. box error	13.0
Sqrt	complex	max. rel. error	6.0
Log	complex	max. box error	13.0
Exp (complex parameter)	complex	max. rel. error	7.0
Exp (imaginary parameter)	complex	max. rel. error	2.0
Sin, Cos, Sinh, and Cosh	complex	max. rel. error	11.0
Tan, Cot, Tanh, and Coth	complex	max. rel. error	35.0
inverse trigonometric	complex	max. rel. error	14.0
inverse hyperbolic	complex	max. rel. error	14.0

8 The maximum relative error given above applies throughout the domain of the Compose_From_Polar function when the Cycle parameter is specified. When the Cycle parameter is omitted, the maximum relative error applies only when the absolute value of the parameter Argument is less than or equal to the angle threshold (see G.2.4). For the Exp function, and for the forward hyperbolic (resp., trigonometric) functions, the maximum relative error given above likewise applies only when the absolute value of the imaginary (resp., real) component of the parameter X (or the absolute value of the parameter itself, in the case of the Exp function with a parameter of pure-imaginary type) is less than or equal to the angle threshold. For larger angles, the accuracy is implementation defined.

8.a **Implementation defined:** The accuracy of certain complex arithmetic operations and certain complex elementary functions for parameters (or components thereof) beyond the angle threshold.

9 The prescribed results specified in G.1.2 for certain functions at particular parameter values take precedence over the error bounds; effectively, they narrow to a single value the result interval allowed by the error bounds for a component of the result. Additional rules with a similar effect are given below for certain inverse trigonometric and inverse hyperbolic functions, at particular parameter values for which a component of the mathematical result is transcendental. In each case, the accuracy rule, which takes precedence over the error bounds, is that the result interval for the stated result component is the model interval of *CT*.Real associated with the component's exact mathematical value. The cases in question are as follows:

10 • When the parameter X has the value zero, the real (resp., imaginary) component of the result of the Arccot (resp., Arccoth) function is in the model interval of *CT*.Real associated with the value π/2.0.

11 • When the parameter X has the value one, the real component of the result of the Arcsin function is in the model interval of *CT*.Real associated with the value π/2.0.

12 • When the parameter X has the value –1.0, the real component of the result of the Arcsin (resp., Arccos) function is in the model interval of *CT*.Real associated with the value –π/2.0 (resp., π).

12.a **Discussion:** It is possible to give many other prescribed results in which a component of the parameter is restricted to a similar model interval when the parameter X is appropriately restricted to an easily testable portion of the domain. We follow the proposed ISO/IEC standard for Generic_Complex_Elementary_Functions (for Ada 83) in not doing so, however.

13/2 {*AI95-00434-01*} The amount by which a component of the result of an inverse trigonometric or inverse hyperbolic function is allowed to spill over into a quadrant adjacent to the one corresponding to the principal branch, as given in G.1.2, is limited. The rule is that the result belongs to the smallest model

interval of *CT*.Real that contains both boundaries of the quadrant corresponding to the principal branch. This rule also takes precedence over the maximum error bounds, effectively narrowing the result interval allowed by them.

Finally, the results allowed by the error bounds are narrowed by one further rule: The absolute value of each component of the result of the Exp function, for a pure-imaginary parameter, never exceeds one. 14

Implementation Advice

The version of the Compose_From_Polar function without a Cycle parameter should not be implemented by calling the corresponding version with a Cycle parameter of 2.0*Numerics.Pi, since this will not provide the required accuracy in some portions of the domain. 15

Implementation Advice: For complex arithmetic, the Compose_From_Polar function without a Cycle parameter should not be implemented by calling Compose_From_Polar with a Cycle parameter. 15.a.1/2

Wording Changes from Ada 83

The semantics of Numerics.Generic_Complex_Types and Numerics.Generic_Complex_Elementary_Functions differs from Generic_Complex_Types and Generic_Complex_Elementary_Functions as defined in ISO/IEC CDs 13813 and 13814 (for Ada 83) in ways analogous to those identified for the elementary functions in G.2.4. In addition, we do not generally specify the signs of zero results (or result components), although those proposed standards do. 15.a

G.3 Vector and Matrix Manipulation

{*AI95-00296-01*} Types and operations for the manipulation of real vectors and matrices are provided in Generic_Real_Arrays, which is defined in G.3.1. Types and operations for the manipulation of complex vectors and matrices are provided in Generic_Complex_Arrays, which is defined in G.3.2. Both of these library units are generic children of the predefined package Numerics (see A.5). Nongeneric equivalents of these packages for each of the predefined floating point types are also provided as children of Numerics. 1/2

Discussion: Vector and matrix manipulation is defined in the Numerics Annex, rather than in the core, because it is considered to be a specialized need of (some) numeric applications. 1.a/2

These packages provide facilities that are similar to and replace those found in ISO/IEC 13813:1998 *Information technology — Programming languages — Generic packages of real and complex type declarations and basic operations for Ada (including vector and matrix types)*. (The other facilities provided by that Standard were already provided in Ada 95.) In addition to the main facilities of that Standard, these packages also include subprograms for the solution of linear equations, matrix inversion, determinants, and the determination of the eigenvalues and eigenvectors of real symmetric matrices and Hermitian matrices. 1.b/2

Extensions to Ada 95

{*AI95-00296-01*} {*AI05-0299-1*} This subclause It just provides an introduction to the following subclauses. 1.c/3

G.3.1 Real Vectors and Matrices

Static Semantics

{*AI95-00296-01*} {*AI95-00418-01*} The generic library package Numerics.Generic_Real_Arrays has the following declaration: 1/2

```
{AI12-0241-1} generic                                                    2/5

```

```
end Ada.Numerics.Generic_Real_Arrays;
```

30/2

{*AI95-00296-01*} The library package Numerics.Real_Arrays is declared pure and defines the same types and subprograms as Numerics.Generic_Real_Arrays, except that the predefined type Float is systematically substituted for Real'Base throughout. Nongeneric equivalents for each of the other predefined floating point types are defined similarly, with the names Numerics.Short_Real_Arrays, Numerics.Long_Real_Arrays, etc.

31/2

Reason: The nongeneric equivalents are provided to allow the programmer to construct simple mathematical applications without being required to understand and use generics, and to be consistent with other Numerics packages.

31.a/2

{*AI95-00296-01*} Two types are defined and exported by Numerics.Generic_Real_Arrays. The composite type Real_Vector is provided to represent a vector with components of type Real; it is defined as an unconstrained, one-dimensional array with an index of type Integer. The composite type Real_Matrix is provided to represent a matrix with components of type Real; it is defined as an unconstrained, two-dimensional array with indices of type Integer.

32/2

{*AI95-00296-01*} The effect of the various subprograms is as described below. In most cases the subprograms are described in terms of corresponding scalar operations of the type Real; any exception raised by those operations is propagated by the array operation. Moreover, the accuracy of the result for each individual component is as defined for the scalar operation unless stated otherwise.

33/2

{*AI95-00296-01*} In the case of those operations which are defined to *involve an inner product*, Constraint_Error may be raised if an intermediate result is outside the range of Real'Base even though the mathematical final result would not be.

34/2

```
function "+"   (Right : Real_Vector) return Real_Vector;
function "-"   (Right : Real_Vector) return Real_Vector;
function "abs" (Right : Real_Vector) return Real_Vector;
```

35/2

{*AI95-00296-01*} Each operation returns the result of applying the corresponding operation of the type Real to each component of Right. The index range of the result is Right'Range.

36/2

```
function "+" (Left, Right : Real_Vector) return Real_Vector;
function "-" (Left, Right : Real_Vector) return Real_Vector;
```

37/2

{*AI95-00296-01*} Each operation returns the result of applying the corresponding operation of the type Real to each component of Left and the matching component of Right. The index range of the result is Left'Range. Constraint_Error is raised if Left'Length is not equal to Right'Length.

38/2

```
function "*" (Left, Right : Real_Vector) return Real'Base;
```

39/2

{*AI95-00296-01*} This operation returns the inner product of Left and Right. Constraint_Error is raised if Left'Length is not equal to Right'Length. This operation involves an inner product.

40/2

```
function "abs" (Right : Real_Vector) return Real'Base;
```

41/2

{*AI95-00418-01*} This operation returns the L2-norm of Right (the square root of the inner product of the vector with itself).

42/2

Discussion: Normalization of vectors is a frequent enough operation that it is useful to provide the norm as a basic operation. Furthermore, implementing the norm is not entirely straightforward, because the inner product might overflow while the final norm does not. An implementation cannot merely return Sqrt (X * X), it has to cope with a possible overflow of the inner product.

42.a/2

Implementation Note: While the definition is given in terms of an inner product, the norm doesn't "involve an inner product" in the technical sense. The reason is that it has accuracy requirements substantially different from those applicable to inner products; and that cancellations cannot occur, because all the terms are positive, so there is no possibility of intermediate overflow.

42.b/2

```
function "*" (Left : Real'Base; Right : Real_Vector) return Real_Vector;
```

43/2

{*AI95-00296-01*} This operation returns the result of multiplying each component of Right by the scalar Left using the "*" operation of the type Real. The index range of the result is Right'Range.

44/2

45/2
```
function "*" (Left : Real_Vector; Right : Real'Base) return Real_Vector;
function "/" (Left : Real_Vector; Right : Real'Base) return Real_Vector;
```

46/2 {*AI95-00296-01*} Each operation returns the result of applying the corresponding operation of the type Real to each component of Left and to the scalar Right. The index range of the result is Left'Range.

47/2
```
function Unit_Vector (Index : Integer;
                      Order : Positive;
                      First : Integer := 1) return Real_Vector;
```

48/2 {*AI95-00296-01*} This function returns a *unit vector* with Order components and a lower bound of First. All components are set to 0.0 except for the Index component which is set to 1.0. Constraint_Error is raised if Index < First, Index > First + Order – 1 or if First + Order – 1 > Integer'Last.

49/2
```
function "+"   (Right : Real_Matrix) return Real_Matrix;
function "-"   (Right : Real_Matrix) return Real_Matrix;
function "abs" (Right : Real_Matrix) return Real_Matrix;
```

50/2 {*AI95-00296-01*} Each operation returns the result of applying the corresponding operation of the type Real to each component of Right. The index ranges of the result are those of Right.

51/2
```
function Transpose (X : Real_Matrix) return Real_Matrix;
```

52/2 {*AI95-00296-01*} This function returns the transpose of a matrix X. The first and second index ranges of the result are X'Range(2) and X'Range(1) respectively.

53/2
```
function "+" (Left, Right : Real_Matrix) return Real_Matrix;
function "-" (Left, Right : Real_Matrix) return Real_Matrix;
```

54/2 {*AI95-00296-01*} Each operation returns the result of applying the corresponding operation of the type Real to each component of Left and the matching component of Right. The index ranges of the result are those of Left. Constraint_Error is raised if Left'Length(1) is not equal to Right'Length(1) or Left'Length(2) is not equal to Right'Length(2).

55/2
```
function "*" (Left, Right : Real_Matrix) return Real_Matrix;
```

56/2 {*AI95-00296-01*} This operation provides the standard mathematical operation for matrix multiplication. The first and second index ranges of the result are Left'Range(1) and Right'Range(2) respectively. Constraint_Error is raised if Left'Length(2) is not equal to Right'Length(1). This operation involves inner products.

57/2
```
function "*" (Left, Right : Real_Vector) return Real_Matrix;
```

58/2 {*AI95-00296-01*} This operation returns the outer product of a (column) vector Left by a (row) vector Right using the operation "*" of the type Real for computing the individual components. The first and second index ranges of the result are Left'Range and Right'Range respectively.

59/2
```
function "*" (Left : Real_Vector; Right : Real_Matrix) return Real_Vector;
```

60/2 {*AI95-00296-01*} This operation provides the standard mathematical operation for multiplication of a (row) vector Left by a matrix Right. The index range of the (row) vector result is Right'Range(2). Constraint_Error is raised if Left'Length is not equal to Right'Length(1). This operation involves inner products.

61/2
```
function "*" (Left : Real_Matrix; Right : Real_Vector) return Real_Vector;
```

62/2 {*AI95-00296-01*} This operation provides the standard mathematical operation for multiplication of a matrix Left by a (column) vector Right. The index range of the (column) vector result is Left'Range(1). Constraint_Error is raised if Left'Length(2) is not equal to Right'Length. This operation involves inner products.

```
function "*" (Left : Real'Base; Right : Real_Matrix) return Real_Matrix;
```
63/2

{*AI95-00296-01*} This operation returns the result of multiplying each component of Right by the scalar Left using the "*" operation of the type Real. The index ranges of the result are those of Right.
64/2

```
function "*" (Left : Real_Matrix; Right : Real'Base) return Real_Matrix;
function "/" (Left : Real_Matrix; Right : Real'Base) return Real_Matrix;
```
65/2

{*AI95-00296-01*} Each operation returns the result of applying the corresponding operation of the type Real to each component of Left and to the scalar Right. The index ranges of the result are those of Left.
66/2

```
function Solve (A : Real_Matrix; X : Real_Vector) return Real_Vector;
```
67/2

{*AI95-00296-01*} This function returns a vector Y such that X is (nearly) equal to A * Y. This is the standard mathematical operation for solving a single set of linear equations. The index range of the result is A'Range(2). Constraint_Error is raised if A'Length(1), A'Length(2), and X'Length are not equal. Constraint_Error is raised if the matrix A is ill-conditioned.
68/2

Discussion: The text says that Y is such that “X is (nearly) equal to A * Y” rather than “X is equal to A * Y” because rounding errors may mean that there is no value of Y such that X is exactly equal to A * Y. On the other hand it does not mean that any old rough value will do. The algorithm given under Implementation Advice should be followed.
68.a/2

The requirement to raise Constraint_Error if the matrix is ill-conditioned is really a reflection of what will happen if the matrix is ill-conditioned. See Implementation Advice. We do not make any attempt to define ill-conditioned formally.
68.b/2

These remarks apply to all versions of Solve and Inverse.
68.c/2

```
function Solve (A, X : Real_Matrix) return Real_Matrix;
```
69/2

{*AI95-00296-01*} This function returns a matrix Y such that X is (nearly) equal to A * Y. This is the standard mathematical operation for solving several sets of linear equations. The index ranges of the result are A'Range(2) and X'Range(2). Constraint_Error is raised if A'Length(1), A'Length(2), and X'Length(1) are not equal. Constraint_Error is raised if the matrix A is ill-conditioned.
70/2

```
function Inverse (A : Real_Matrix) return Real_Matrix;
```
71/2

{*AI95-00296-01*} This function returns a matrix B such that A * B is (nearly) equal to the unit matrix. The index ranges of the result are A'Range(2) and A'Range(1). Constraint_Error is raised if A'Length(1) is not equal to A'Length(2). Constraint_Error is raised if the matrix A is ill-conditioned.
72/2

```
function Determinant (A : Real_Matrix) return Real'Base;
```
73/2

{*AI95-00296-01*} This function returns the determinant of the matrix A. Constraint_Error is raised if A'Length(1) is not equal to A'Length(2).
74/2

```
function Eigenvalues(A : Real_Matrix) return Real_Vector;
```
75/2

{*AI95-00296-01*} This function returns the eigenvalues of the symmetric matrix A as a vector sorted into order with the largest first. Constraint_Error is raised if A'Length(1) is not equal to A'Length(2). The index range of the result is A'Range(1). Argument_Error is raised if the matrix A is not symmetric.
76/2

```
procedure Eigensystem(A       : in  Real_Matrix;
                      Values  : out Real_Vector;
                      Vectors : out Real_Matrix);
```
77/2

{*AI95-00296-01*} {*AI05-0047-1*} This procedure computes both the eigenvalues and eigenvectors of the symmetric matrix A. The out parameter Values is the same as that obtained by calling the function Eigenvalues. The out parameter Vectors is a matrix whose columns are the eigenvectors of the matrix A. The order of the columns corresponds to the order of the eigenvalues. The
78/3

eigenvectors are normalized and mutually orthogonal (they are orthonormal), including when there are repeated eigenvalues. Constraint_Error is raised if A'Length(1) is not equal to A'Length(2), or if Values'Range is not equal to A'Range(1), or if the index ranges of the parameter Vectors are not equal to those of A. Argument_Error is raised if the matrix A is not symmetric. Constraint_Error is also raised in implementation-defined circumstances if the algorithm used does not converge quickly enough.

78.a/3 **Ramification:** {*AI05-0047-1*} There is no requirement on the absolute direction of the returned eigenvectors. Thus they might be multiplied by -1. It is only the ratios of the components that matter. This is standard practice.

79/2
```
function Unit_Matrix (Order            : Positive;
                      First_1, First_2 : Integer := 1) return Real_Matrix;
```

80/2 {*AI95-00296-01*} This function returns a square *unit matrix* with Order**2 components and lower bounds of First_1 and First_2 (for the first and second index ranges respectively). All components are set to 0.0 except for the main diagonal, whose components are set to 1.0. Constraint_Error is raised if First_1 + Order – 1 > Integer'Last or First_2 + Order – 1 > Integer'Last.

Implementation Requirements

81/2 {*AI95-00296-01*} Accuracy requirements for the subprograms Solve, Inverse, Determinant, Eigenvalues and Eigensystem are implementation defined.

81.a/2 **Implementation defined:** The accuracy requirements for the subprograms Solve, Inverse, Determinant, Eigenvalues and Eigensystem for type Real_Matrix.

82/2 For operations not involving an inner product, the accuracy requirements are those of the corresponding operations of the type Real in both the strict mode and the relaxed mode (see G.2).

83/2 For operations involving an inner product, no requirements are specified in the relaxed mode. In the strict mode the modulus of the absolute error of the inner product *X***Y* shall not exceed *g***abs*(*X*)***abs*(*Y*) where *g* is defined as

84/2 *g* = *X*'Length * Real'Machine_Radix**(1 – Real'Model_Mantissa)

85/2 {*AI95-00418-01*} For the L2-norm, no accuracy requirements are specified in the relaxed mode. In the strict mode the relative error on the norm shall not exceed *g* / 2.0 + 3.0 * Real'Model_Epsilon where *g* is defined as above.

85.a/2 **Reason:** This is simply the combination of the error on the inner product with the error on Sqrt. A first order computation would lead to 2.0 * Real'Model_Epsilon above, but we are adding an extra Real'Model_Epsilon to account for higher order effects.

Documentation Requirements

86/2 {*AI95-00296-01*} Implementations shall document any techniques used to reduce cancellation errors such as extended precision arithmetic.

86.a/2 **Documentation Requirement:** Any techniques used to reduce cancellation errors in Numerics.Generic_Real_Arrays shall be documented.

86.b/2 **Implementation Note:** The above accuracy requirement is met by the canonical implementation of the inner product by multiplication and addition using the corresponding operations of type Real'Base and performing the cumulative addition using ascending indices. Note however, that some hardware provides special operations for the computation of the inner product and although these may be fast they may not meet the accuracy requirement specified. See Accuracy and Stability of Numerical Algorithms By N J Higham (ISBN 0-89871-355-2), Section 3.1.

86.c/3 {*AI05-0047-1*} Note moreover that the componentwise accuracy requirements are not met by subcubic methods for matrix multiplication such as that devised by Strassen. These methods, which are typically used for the fast multiplication of very large matrices (that is, order more than a few thousands), have normwise accuracy properties. If it is desired to use such methods, then distinct subprograms should be provided (perhaps in a child package). See Section 22.2.2 in the above reference.

Implementation Permissions

{*AI95-00296-01*} {*AI12-0444-1*} The nongeneric equivalent packages can be actual instantiations of the generic package for the appropriate predefined type, though that is not required. 87/5

Implementation Advice

{*AI95-00296-01*} {*AI05-0264-1*} Implementations should implement the Solve and Inverse functions using established techniques such as LU decomposition with row interchanges followed by back and forward substitution. Implementations are recommended to refine the result by performing an iteration on the residuals; if this is done, then it should be documented. 88/3

Implementation Advice: Solve and Inverse for Numerics.Generic_Real_Arrays should be implemented using established techniques such as LU decomposition and the result should be refined by an iteration on the residuals. 88.a/2

It is not the intention that any special provision should be made to determine whether a matrix is ill-conditioned or not. The naturally occurring overflow (including division by zero) which will result from executing these functions with an ill-conditioned matrix and thus raise Constraint_Error is sufficient. 89/2

Discussion: There isn't any advice for the implementation to document with this paragraph. 89.a/2

The test that a matrix is symmetric should be performed by using the equality operator to compare the relevant components. 90/2

Implementation Advice: The equality operator should be used to test that a matrix in Numerics.Generic_Real_Arrays is symmetric. 90.a/2

{*AI05-0047-1*} An implementation should minimize the circumstances under which the algorithm used for Eigenvalues and Eigensystem fails to converge. 91/3

Implementation Advice: An implementation should minimize the circumstances under which the algorithm used for Numerics.Generic_Real_Arrays.Eigenvalues and Numerics.Generic_Real_Arrays.Eigensystem fails to converge. 91.a.1/3

Implementation Note: J. H. Wilkinson is the acknowledged expert in this area. See for example Wilkinson, J. H., and Reinsch, C. , Linear Algebra , vol II of Handbook for Automatic Computation, Springer-Verlag, or Wilkinson, J. H., The Algebraic Eigenvalue Problem, Oxford University Press. 91.a/3

Extensions to Ada 95

{*AI95-00296-01*} The package Numerics.Generic_Real_Arrays and its nongeneric equivalents are new. 91.b/2

Wording Changes from Ada 2005

{*AI05-0047-1*} **Correction:** Corrected various accuracy and definition issues. 91.c/3

G.3.2 Complex Vectors and Matrices

Static Semantics

{*AI95-00296-01*} The generic library package Numerics.Generic_Complex_Arrays has the following declaration: 1/2

```

                          Right : Real'Base)      return Complex_Matrix;
45/2        -- Complex_Matrix inversion and related operations
46/2        function Solve (A : Complex_Matrix; X : Complex_Vector)
               return Complex_Vector;
            function Solve (A, X : Complex_Matrix) return Complex_Matrix;
            function Inverse (A : Complex_Matrix) return Complex_Matrix;
            function Determinant (A : Complex_Matrix) return Complex;
47/2        -- Eigenvalues and vectors of a Hermitian matrix
48/2        function Eigenvalues(A : Complex_Matrix) return Real_Vector;
49/2        procedure Eigensystem(A       : in  Complex_Matrix;
                                  Values  : out Real_Vector;
                                  Vectors : out Complex_Matrix);
50/2        -- Other Complex_Matrix operations
51/2        function Unit_Matrix (Order            : Positive;
                                  First_1, First_2 : Integer := 1)
                                    return Complex_Matrix;
52/2    end Ada.Numerics.Generic_Complex_Arrays;
```

53/2 {*AI95-00296-01*} The library package Numerics.Complex_Arrays is declared pure and defines the same types and subprograms as Numerics.Generic_Complex_Arrays, except that the predefined type Float is systematically substituted for Real'Base, and the Real_Vector and Real_Matrix types exported by Numerics.Real_Arrays are systematically substituted for Real_Vector and Real_Matrix, and the Complex type exported by Numerics.Complex_Types is systematically substituted for Complex, throughout. Nongeneric equivalents for each of the other predefined floating point types are defined similarly, with the names Numerics.Short_Complex_Arrays, Numerics.Long_Complex_Arrays, etc.

54/2 {*AI95-00296-01*} Two types are defined and exported by Numerics.Generic_Complex_Arrays. The composite type Complex_Vector is provided to represent a vector with components of type Complex; it is defined as an unconstrained one-dimensional array with an index of type Integer. The composite type Complex_Matrix is provided to represent a matrix with components of type Complex; it is defined as an unconstrained, two-dimensional array with indices of type Integer.

55/2 {*AI95-00296-01*} The effect of the various subprograms is as described below. In many cases they are described in terms of corresponding scalar operations in Numerics.Generic_Complex_Types. Any

exception raised by those operations is propagated by the array subprogram. Moreover, any constraints on the parameters and the accuracy of the result for each individual component are as defined for the scalar operation.

{*AI95-00296-01*} In the case of those operations which are defined to *involve an inner product*, Constraint_Error may be raised if an intermediate result has a component outside the range of Real'Base even though the final mathematical result would not. 56/2

Discussion: {*AI05-0047-1*} An inner product never involves implicit complex conjugation. If the product of a vector with the conjugate of another (or the same) vector is required, then this has to be stated explicitly by writing for example X * Conjugate(Y). This mimics the usual mathematical notation. 56.a/3

```
function Re (X : Complex_Vector) return Real_Vector;
function Im (X : Complex_Vector) return Real_Vector;
```
57/2

{*AI95-00296-01*} Each function returns a vector of the specified Cartesian components of X. The index range of the result is X'Range. 58/2

```
procedure Set_Re (X  : in out Complex_Vector; Re : in Real_Vector);
procedure Set_Im (X  : in out Complex_Vector; Im : in Real_Vector);
```
59/2

{*AI95-00296-01*} Each procedure replaces the specified (Cartesian) component of each of the components of X by the value of the matching component of Re or Im; the other (Cartesian) component of each of the components is unchanged. Constraint_Error is raised if X'Length is not equal to Re'Length or Im'Length. 60/2

```
function Compose_From_Cartesian (Re     : Real_Vector)
   return Complex_Vector;
function Compose_From_Cartesian (Re, Im : Real_Vector)
   return Complex_Vector;
```
61/2

{*AI95-00296-01*} Each function constructs a vector of Complex results (in Cartesian representation) formed from given vectors of Cartesian components; when only the real components are given, imaginary components of zero are assumed. The index range of the result is Re'Range. Constraint_Error is raised if Re'Length is not equal to Im'Length. 62/2

```
function Modulus  (X     : Complex_Vector) return Real_Vector;
function "abs"    (Right : Complex_Vector) return Real_Vector
                                              renames Modulus;
function Argument (X     : Complex_Vector) return Real_Vector;
function Argument (X     : Complex_Vector;
                   Cycle : Real'Base)      return Real_Vector;
```
63/2

{*AI95-00296-01*} Each function calculates and returns a vector of the specified polar components of X or Right using the corresponding function in numerics.generic_complex_types. The index range of the result is X'Range or Right'Range. 64/2

```
function Compose_From_Polar (Modulus, Argument : Real_Vector)
   return Complex_Vector;
function Compose_From_Polar (Modulus, Argument : Real_Vector;
                             Cycle             : Real'Base)
   return Complex_Vector;
```
65/2

{*AI95-00296-01*} Each function constructs a vector of Complex results (in Cartesian representation) formed from given vectors of polar components using the corresponding function in numerics.generic_complex_types on matching components of Modulus and Argument. The index range of the result is Modulus'Range. Constraint_Error is raised if Modulus'Length is not equal to Argument'Length. 66/2

67/2
```
function "+" (Right : Complex_Vector) return Complex_Vector;
function "-" (Right : Complex_Vector) return Complex_Vector;
```

68/2 {*AI95-00296-01*} Each operation returns the result of applying the corresponding operation in numerics.generic_complex_types to each component of Right. The index range of the result is Right'Range.

69/2
```
function Conjugate (X : Complex_Vector) return Complex_Vector;
```

70/2 {*AI95-00296-01*} This function returns the result of applying the appropriate function Conjugate in numerics.generic_complex_types to each component of X. The index range of the result is X'Range.

71/2
```
function "+" (Left, Right : Complex_Vector) return Complex_Vector;
function "-" (Left, Right : Complex_Vector) return Complex_Vector;
```

72/2 {*AI95-00296-01*} Each operation returns the result of applying the corresponding operation in numerics.generic_complex_types to each component of Left and the matching component of Right. The index range of the result is Left'Range. Constraint_Error is raised if Left'Length is not equal to Right'Length.

73/2
```
function "*" (Left, Right : Complex_Vector) return Complex;
```

74/2 {*AI95-00296-01*} This operation returns the inner product of Left and Right. Constraint_Error is raised if Left'Length is not equal to Right'Length. This operation involves an inner product.

75/3
```
{AI05-0047-1} function "abs" (Right : Complex_Vector) return Real'Base;
```

76/2 {*AI95-00418-01*} This operation returns the Hermitian L2-norm of Right (the square root of the inner product of the vector with its conjugate).

76.a/2 **Implementation Note:** While the definition is given in terms of an inner product, the norm doesn't "involve an inner product" in the technical sense. The reason is that it has accuracy requirements substantially different from those applicable to inner products; and that cancellations cannot occur, because all the terms are positive, so there is no possibility of intermediate overflow.

77/2
```
function "+" (Left  : Real_Vector;
              Right : Complex_Vector) return Complex_Vector;
function "+" (Left  : Complex_Vector;
              Right : Real_Vector)    return Complex_Vector;
function "-" (Left  : Real_Vector;
              Right : Complex_Vector) return Complex_Vector;
function "-" (Left  : Complex_Vector;
              Right : Real_Vector)    return Complex_Vector;
```

78/2 {*AI95-00296-01*} Each operation returns the result of applying the corresponding operation in numerics.generic_complex_types to each component of Left and the matching component of Right. The index range of the result is Left'Range. Constraint_Error is raised if Left'Length is not equal to Right'Length.

79/2
```
function "*" (Left : Real_Vector;    Right : Complex_Vector) return Complex;
function "*" (Left : Complex_Vector; Right : Real_Vector)    return Complex;
```

80/2 {*AI95-00296-01*} Each operation returns the inner product of Left and Right. Constraint_Error is raised if Left'Length is not equal to Right'Length. These operations involve an inner product.

81/2
```
function "*" (Left : Complex; Right : Complex_Vector) return Complex_Vector;
```

82/2 {*AI95-00296-01*} This operation returns the result of multiplying each component of Right by the complex number Left using the appropriate operation "*" in numerics.generic_complex_types. The index range of the result is Right'Range.

```
function "*" (Left : Complex_Vector; Right : Complex) return Complex_Vector;
function "/" (Left : Complex_Vector; Right : Complex) return Complex_Vector;
```
83/2

{*AI95-00296-01*} Each operation returns the result of applying the corresponding operation in numerics.generic_complex_types to each component of the vector Left and the complex number Right. The index range of the result is Left'Range.
84/2

```
function "*" (Left : Real'Base;
              Right : Complex_Vector) return Complex_Vector;
```
85/2

{*AI95-00296-01*} This operation returns the result of multiplying each component of Right by the real number Left using the appropriate operation "*" in numerics.generic_complex_types. The index range of the result is Right'Range.
86/2

```
function "*" (Left : Complex_Vector;
              Right : Real'Base) return Complex_Vector;
function "/" (Left : Complex_Vector;
              Right : Real'Base) return Complex_Vector;
```
87/2

{*AI95-00296-01*} Each operation returns the result of applying the corresponding operation in numerics.generic_complex_types to each component of the vector Left and the real number Right. The index range of the result is Left'Range.
88/2

```
function Unit_Vector (Index : Integer;
                      Order : Positive;
                      First : Integer := 1) return Complex_Vector;
```
89/2

{*AI95-00296-01*} This function returns a *unit vector* with Order components and a lower bound of First. All components are set to (0.0, 0.0) except for the Index component which is set to (1.0, 0.0). Constraint_Error is raised if Index < First, Index > First + Order – 1, or if First + Order – 1 > Integer'Last.
90/2

```
function Re (X : Complex_Matrix) return Real_Matrix;
function Im (X : Complex_Matrix) return Real_Matrix;
```
91/2

{*AI95-00296-01*} Each function returns a matrix of the specified Cartesian components of X. The index ranges of the result are those of X.
92/2

```
procedure Set_Re (X : in out Complex_Matrix; Re : in Real_Matrix);
procedure Set_Im (X : in out Complex_Matrix; Im : in Real_Matrix);
```
93/2

{*AI95-00296-01*} Each procedure replaces the specified (Cartesian) component of each of the components of X by the value of the matching component of Re or Im; the other (Cartesian) component of each of the components is unchanged. Constraint_Error is raised if X'Length(1) is not equal to Re'Length(1) or Im'Length(1) or if X'Length(2) is not equal to Re'Length(2) or Im'Length(2).
94/2

```
function Compose_From_Cartesian (Re     : Real_Matrix)
   return Complex_Matrix;
function Compose_From_Cartesian (Re, Im : Real_Matrix)
   return Complex_Matrix;
```
95/2

{*AI95-00296-01*} Each function constructs a matrix of Complex results (in Cartesian representation) formed from given matrices of Cartesian components; when only the real components are given, imaginary components of zero are assumed. The index ranges of the result are those of Re. Constraint_Error is raised if Re'Length(1) is not equal to Im'Length(1) or Re'Length(2) is not equal to Im'Length(2).
96/2

97/2
```
function Modulus  (X     : Complex_Matrix) return Real_Matrix;
function "abs"    (Right : Complex_Matrix) return Real_Matrix
                                              renames Modulus;
function Argument (X     : Complex_Matrix) return Real_Matrix;
function Argument (X     : Complex_Matrix;
                   Cycle : Real'Base)      return Real_Matrix;
```

98/2 {*AI95-00296-01*} Each function calculates and returns a matrix of the specified polar components of X or Right using the corresponding function in numerics.generic_complex_types. The index ranges of the result are those of X or Right.

99/2
```
function Compose_From_Polar (Modulus, Argument : Real_Matrix)
   return Complex_Matrix;
function Compose_From_Polar (Modulus, Argument : Real_Matrix;
                             Cycle             : Real'Base)
   return Complex_Matrix;
```

100/2 {*AI95-00296-01*} Each function constructs a matrix of Complex results (in Cartesian representation) formed from given matrices of polar components using the corresponding function in numerics.generic_complex_types on matching components of Modulus and Argument. The index ranges of the result are those of Modulus. Constraint_Error is raised if Modulus'Length(1) is not equal to Argument'Length(1) or Modulus'Length(2) is not equal to Argument'Length(2).

101/2
```
function "+" (Right : Complex_Matrix) return Complex_Matrix;
function "-" (Right : Complex_Matrix) return Complex_Matrix;
```

102/2 {*AI95-00296-01*} Each operation returns the result of applying the corresponding operation in numerics.generic_complex_types to each component of Right. The index ranges of the result are those of Right.

103/2
```
function Conjugate (X : Complex_Matrix) return Complex_Matrix;
```

104/2 {*AI95-00296-01*} This function returns the result of applying the appropriate function Conjugate in numerics.generic_complex_types to each component of X. The index ranges of the result are those of X.

105/2
```
function Transpose (X : Complex_Matrix) return Complex_Matrix;
```

106/2 {*AI95-00296-01*} This function returns the transpose of a matrix X. The first and second index ranges of the result are X'Range(2) and X'Range(1) respectively.

107/2
```
function "+" (Left, Right : Complex_Matrix) return Complex_Matrix;
function "-" (Left, Right : Complex_Matrix) return Complex_Matrix;
```

108/2 {*AI95-00296-01*} Each operation returns the result of applying the corresponding operation in numerics.generic_complex_types to each component of Left and the matching component of Right. The index ranges of the result are those of Left. Constraint_Error is raised if Left'Length(1) is not equal to Right'Length(1) or Left'Length(2) is not equal to Right'Length(2).

109/2
```
function "*" (Left, Right : Complex_Matrix) return Complex_Matrix;
```

110/2 {*AI95-00296-01*} This operation provides the standard mathematical operation for matrix multiplication. The first and second index ranges of the result are Left'Range(1) and Right'Range(2) respectively. Constraint_Error is raised if Left'Length(2) is not equal to Right'Length(1). This operation involves inner products.

111/2
```
function "*" (Left, Right : Complex_Vector) return Complex_Matrix;
```

112/2 {*AI95-00296-01*} This operation returns the outer product of a (column) vector Left by a (row) vector Right using the appropriate operation "*" in numerics.generic_complex_types for computing the individual components. The first and second index ranges of the result are Left'Range and Right'Range respectively.

```
function "*" (Left  : Complex_Vector;
              Right : Complex_Matrix) return Complex_Vector;
```
113/2

{*AI95-00296-01*} This operation provides the standard mathematical operation for multiplication of a (row) vector Left by a matrix Right. The index range of the (row) vector result is Right'Range(2). Constraint_Error is raised if Left'Length is not equal to Right'Length(1). This operation involves inner products.
114/2

```
function "*" (Left  : Complex_Matrix;
              Right : Complex_Vector) return Complex_Vector;
```
115/2

{*AI95-00296-01*} This operation provides the standard mathematical operation for multiplication of a matrix Left by a (column) vector Right. The index range of the (column) vector result is Left'Range(1). Constraint_Error is raised if Left'Length(2) is not equal to Right'Length. This operation involves inner products.
116/2

```
function "+" (Left  : Real_Matrix;
              Right : Complex_Matrix) return Complex_Matrix;
function "+" (Left  : Complex_Matrix;
              Right : Real_Matrix)    return Complex_Matrix;
function "-" (Left  : Real_Matrix;
              Right : Complex_Matrix) return Complex_Matrix;
function "-" (Left  : Complex_Matrix;
              Right : Real_Matrix)    return Complex_Matrix;
```
117/2

{*AI95-00296-01*} Each operation returns the result of applying the corresponding operation in numerics.generic_complex_types to each component of Left and the matching component of Right. The index ranges of the result are those of Left. Constraint_Error is raised if Left'Length(1) is not equal to Right'Length(1) or Left'Length(2) is not equal to Right'Length(2).
118/2

```
function "*" (Left  : Real_Matrix;
              Right : Complex_Matrix) return Complex_Matrix;
function "*" (Left  : Complex_Matrix;
              Right : Real_Matrix)    return Complex_Matrix;
```
119/2

{*AI95-00296-01*} Each operation provides the standard mathematical operation for matrix multiplication. The first and second index ranges of the result are Left'Range(1) and Right'Range(2) respectively. Constraint_Error is raised if Left'Length(2) is not equal to Right'Length(1). These operations involve inner products.
120/2

```
function "*" (Left  : Real_Vector;
              Right : Complex_Vector) return Complex_Matrix;
function "*" (Left  : Complex_Vector;
              Right : Real_Vector)    return Complex_Matrix;
```
121/2

{*AI95-00296-01*} Each operation returns the outer product of a (column) vector Left by a (row) vector Right using the appropriate operation "*" in numerics.generic_complex_types for computing the individual components. The first and second index ranges of the result are Left'Range and Right'Range respectively.
122/2

```
function "*" (Left  : Real_Vector;
              Right : Complex_Matrix) return Complex_Vector;
function "*" (Left  : Complex_Vector;
              Right : Real_Matrix)    return Complex_Vector;
```
123/2

{*AI95-00296-01*} Each operation provides the standard mathematical operation for multiplication of a (row) vector Left by a matrix Right. The index range of the (row) vector result is Right'Range(2). Constraint_Error is raised if Left'Length is not equal to Right'Length(1). These operations involve inner products.
124/2

125/2
```
function "*" (Left  : Real_Matrix;
              Right : Complex_Vector) return Complex_Vector;
function "*" (Left  : Complex_Matrix;
              Right : Real_Vector)    return Complex_Vector;
```

126/2 {*AI95-00296-01*} Each operation provides the standard mathematical operation for multiplication of a matrix Left by a (column) vector Right. The index range of the (column) vector result is Left'Range(1). Constraint_Error is raised if Left'Length(2) is not equal to Right'Length. These operations involve inner products.

127/2
```
function "*" (Left : Complex; Right : Complex_Matrix) return Complex_Matrix;
```

128/2 {*AI95-00296-01*} This operation returns the result of multiplying each component of Right by the complex number Left using the appropriate operation "*" in numerics.generic_complex_types. The index ranges of the result are those of Right.

129/2
```
function "*" (Left : Complex_Matrix; Right : Complex) return Complex_Matrix;
function "/" (Left : Complex_Matrix; Right : Complex) return Complex_Matrix;
```

130/2 {*AI95-00296-01*} Each operation returns the result of applying the corresponding operation in numerics.generic_complex_types to each component of the matrix Left and the complex number Right. The index ranges of the result are those of Left.

131/2
```
function "*" (Left : Real'Base;
              Right : Complex_Matrix) return Complex_Matrix;
```

132/2 {*AI95-00296-01*} This operation returns the result of multiplying each component of Right by the real number Left using the appropriate operation "*" in numerics.generic_complex_types. The index ranges of the result are those of Right.

133/2
```
function "*" (Left : Complex_Matrix;
              Right : Real'Base) return Complex_Matrix;
function "/" (Left : Complex_Matrix;
              Right : Real'Base) return Complex_Matrix;
```

134/2 {*AI95-00296-01*} Each operation returns the result of applying the corresponding operation in numerics.generic_complex_types to each component of the matrix Left and the real number Right. The index ranges of the result are those of Left.

135/2
```
function Solve (A : Complex_Matrix; X : Complex_Vector) return Complex_Vector;
```

136/2 {*AI95-00296-01*} This function returns a vector Y such that X is (nearly) equal to A * Y. This is the standard mathematical operation for solving a single set of linear equations. The index range of the result is A'Range(2). Constraint_Error is raised if A'Length(1), A'Length(2), and X'Length are not equal. Constraint_Error is raised if the matrix A is ill-conditioned.

136.a/2 **Discussion:** The text says that Y is such that “X is (nearly) equal to A * Y” rather than “X is equal to A * Y” because rounding errors may mean that there is no value of Y such that X is exactly equal to A * Y. On the other hand it does not mean that any old rough value will do. The algorithm given under Implementation Advice should be followed.

136.b/2 The requirement to raise Constraint_Error if the matrix is ill-conditioned is really a reflection of what will happen if the matrix is ill-conditioned. See Implementation Advice. We do not make any attempt to define ill-conditioned formally.

136.c/2 These remarks apply to all versions of Solve and Inverse.

137/2
```
function Solve (A, X : Complex_Matrix) return Complex_Matrix;
```

138/2 {*AI95-00296-01*} This function returns a matrix Y such that X is (nearly) equal to A * Y. This is the standard mathematical operation for solving several sets of linear equations. The index ranges of the result are A'Range(2) and X'Range(2). Constraint_Error is raised if A'Length(1), A'Length(2), and X'Length(1) are not equal. Constraint_Error is raised if the matrix A is ill-conditioned.

```
function Inverse (A : Complex_Matrix) return Complex_Matrix;
```
139/2

{*AI95-00296-01*} This function returns a matrix B such that A * B is (nearly) equal to the unit matrix. The index ranges of the result are A'Range(2) and A'Range(1). Constraint_Error is raised if A'Length(1) is not equal to A'Length(2). Constraint_Error is raised if the matrix A is ill-conditioned.
140/2

```
function Determinant (A : Complex_Matrix) return Complex;
```
141/2

{*AI95-00296-01*} This function returns the determinant of the matrix A. Constraint_Error is raised if A'Length(1) is not equal to A'Length(2).
142/2

```
function Eigenvalues(A : Complex_Matrix) return Real_Vector;
```
143/2

{*AI95-00296-01*} This function returns the eigenvalues of the Hermitian matrix A as a vector sorted into order with the largest first. Constraint_Error is raised if A'Length(1) is not equal to A'Length(2). The index range of the result is A'Range(1). Argument_Error is raised if the matrix A is not Hermitian.
144/2

Discussion: A Hermitian matrix is one whose transpose is equal to its complex conjugate. The eigenvalues of a Hermitian matrix are always real. We only support this case because algorithms for solving the general case are inherently unstable.
144.a/2

```
procedure Eigensystem(A       : in  Complex_Matrix;
                      Values  :  out Real_Vector;
                      Vectors :  out Complex_Matrix);
```
145/2

{*AI95-00296-01*} {*AI05-0047-1*} This procedure computes both the eigenvalues and eigenvectors of the Hermitian matrix A. The out parameter Values is the same as that obtained by calling the function Eigenvalues. The out parameter Vectors is a matrix whose columns are the eigenvectors of the matrix A. The order of the columns corresponds to the order of the eigenvalues. The eigenvectors are mutually orthonormal, including when there are repeated eigenvalues. Constraint_Error is raised if A'Length(1) is not equal to A'Length(2), or if Values'Range is not equal to A'Range(1), or if the index ranges of the parameter Vectors are not equal to those of A. Argument_Error is raised if the matrix A is not Hermitian. Constraint_Error is also raised in implementation-defined circumstances if the algorithm used does not converge quickly enough.
146/3

Ramification: {*AI05-0047-1*} There is no requirement on the absolute direction of the returned eigenvectors. Thus they might be multiplied by any complex number whose modulus is 1. It is only the ratios of the components that matter. This is standard practice.
146.a/3

```
function Unit_Matrix (Order            : Positive;
                      First_1, First_2 : Integer := 1)
                                         return Complex_Matrix;
```
147/2

{*AI95-00296-01*} This function returns a square *unit matrix* with Order**2 components and lower bounds of First_1 and First_2 (for the first and second index ranges respectively). All components are set to (0.0, 0.0) except for the main diagonal, whose components are set to (1.0, 0.0). Constraint_Error is raised if First_1 + Order – 1 > Integer'Last or First_2 + Order – 1 > Integer'Last.
148/2

Implementation Requirements

{*AI95-00296-01*} Accuracy requirements for the subprograms Solve, Inverse, Determinant, Eigenvalues and Eigensystem are implementation defined.
149/2

Implementation defined: The accuracy requirements for the subprograms Solve, Inverse, Determinant, Eigenvalues and Eigensystem for type Complex_Matrix.
149.a/2

{*AI95-00296-01*} For operations not involving an inner product, the accuracy requirements are those of the corresponding operations of the type Real'Base and Complex in both the strict mode and the relaxed mode (see G.2).
150/2

151/2 {*AI95-00296-01*} For operations involving an inner product, no requirements are specified in the relaxed mode. In the strict mode the modulus of the absolute error of the inner product *X***Y* shall not exceed *g****abs**(*X*)***abs**(*Y*) where *g* is defined as

152/2 *g* = *X*'Length * Real'Machine_Radix**(1 – Real'Model_Mantissa)
for mixed complex and real operands

153/2 *g* = sqrt(2.0) * *X*'Length * Real'Machine_Radix**(1 – Real'Model_Mantissa)
for two complex operands

154/2 {*AI95-00418-01*} For the L2-norm, no accuracy requirements are specified in the relaxed mode. In the strict mode the relative error on the norm shall not exceed *g* / 2.0 + 3.0 * Real'Model_Epsilon where *g* has the definition appropriate for two complex operands.

Documentation Requirements

155/2 {*AI95-00296-01*} Implementations shall document any techniques used to reduce cancellation errors such as extended precision arithmetic.

155.a/2 **Documentation Requirement:** Any techniques used to reduce cancellation errors in Numerics.Generic_Complex_Arrays shall be documented.

155.b/2 **Implementation Note:** The above accuracy requirement is met by the canonical implementation of the inner product by multiplication and addition using the corresponding operations of type Complex and performing the cumulative addition using ascending indices. Note however, that some hardware provides special operations for the computation of the inner product and although these may be fast they may not meet the accuracy requirement specified. See Accuracy and Stability of Numerical Algorithms by N J Higham (ISBN 0-89871-355-2), Sections 3.1 and 3.6.

Implementation Permissions

156/5 {*AI95-00296-01*} {*AI12-0444-1*} The nongeneric equivalent packages can be actual instantiations of the generic package for the appropriate predefined type, though that is not required.

157/5 {*AI95-00296-01*} {*AI12-0444-1*} Although many operations are defined in terms of operations from Numerics.Generic_Complex_Types, they can be implemented by other operations that have the same effect.

Implementation Advice

158/3 {*AI95-00296-01*} {*AI05-0264-1*} Implementations should implement the Solve and Inverse functions using established techniques. Implementations are recommended to refine the result by performing an iteration on the residuals; if this is done, then it should be documented.

158.a/2 **Implementation Advice:** Solve and Inverse for Numerics.Generic_Complex_Arrays should be implemented using established techniques and the result should be refined by an iteration on the residuals.

159/2 {*AI95-00296-01*} It is not the intention that any special provision should be made to determine whether a matrix is ill-conditioned or not. The naturally occurring overflow (including division by zero) which will result from executing these functions with an ill-conditioned matrix and thus raise Constraint_Error is sufficient.

159.a/2 **Discussion:** There isn't any advice for the implementation to document with this paragraph.

160/2 {*AI95-00296-01*} The test that a matrix is Hermitian should use the equality operator to compare the real components and negation followed by equality to compare the imaginary components (see G.2.1).

160.a/2 **Implementation Advice:** The equality and negation operators should be used to test that a matrix is Hermitian.

160.1/3 An implementation should minimize the circumstances under which the algorithm used for Eigenvalues and Eigensystem fails to converge.

Implementation Advice: An implementation should minimize the circumstances under which the algorithm used for Numerics.Generic_Complex_Arrays.Eigenvalues and Numerics.Generic_Complex_Arrays.Eigensystem fails to converge. 160.a.1/3

Implementation Note: J. H. Wilkinson is the acknowledged expert in this area. See for example Wilkinson, J. H., and Reinsch, C. , Linear Algebra , vol II of Handbook for Automatic Computation, Springer-Verlag, or Wilkinson, J. H., The Algebraic Eigenvalue Problem, Oxford University Press. 160.b/3

{*AI95-00296-01*} Implementations should not perform operations on mixed complex and real operands by first converting the real operand to complex. See G.1.1. 161/2

Implementation Advice: Mixed real and complex operations should not be performed by converting the real operand to complex. 161.a/2

Extensions to Ada 95

{*AI95-00296-01*} The package Numerics.Generic_Complex_Arrays and its nongeneric equivalents are new. 161.b/2

Wording Changes from Ada 2005

{*AI05-0047-1*} **Correction:** Corrected various accuracy and definition issues. 161.c/3

Annex H
(normative)
High Integrity Systems

{*AI95-00347-01*} This Annex addresses requirements for high integrity systems (including safety-critical systems and security-critical systems). It provides facilities and specifies documentation requirements that relate to several needs: 1/2

- Understanding program execution; 2
- Reviewing object code; 3
- {*AI12-0439-1*} Restricting language constructs whose usage can complicate the demonstration of program correctness 4/5

Execution understandability is supported by pragma Normalize_Scalars, and also by requirements for the implementation to document the effect of a program in the presence of a bounded error or where the language rules leave the effect unspecified. 4.1

The pragmas Reviewable and Restrictions relate to the other requirements addressed by this Annex. 5

NOTE {*AI12-0440-1*} The Valid attribute (see 13.9.2) is also useful in addressing these needs, to avoid problems that can otherwise arise from scalars that have values outside their declared range constraints. 6/5

Discussion: The Annex tries to provide high assurance rather than language features. However, it is not possible, in general, to test for high assurance. For any specific language feature, it is possible to demonstrate its presence by a functional test, as in the ACVC. One can also check for the presence of some documentation requirements, but it is not easy to determine objectively that the documentation is “adequate”. 6.a

Extensions to Ada 83

This Annex is new to Ada 95. 6.b

Wording Changes from Ada 95

{*AI95-00347-01*} The title of this annex was changed to better reflect its purpose and scope. High integrity systems has become the standard way of identifying systems that have high reliability requirements; it subsumes terms such as safety and security. Moreover, the annex does not include any security specific features and as such the previous title is somewhat misleading. 6.c/2

H.1 Pragma Normalize_Scalars

This pragma ensures that an otherwise uninitialized scalar object is set to a predictable value, but out of range if possible. 1

Discussion: The goal of the pragma is to reduce the impact of a bounded error that results from a reference to an uninitialized scalar object, by having such a reference violate a range check and thus raise Constraint_Error. 1.a

Syntax

The form of a pragma Normalize_Scalars is as follows: 2

pragma Normalize_Scalars; 3

Post-Compilation Rules

Pragma Normalize_Scalars is a configuration pragma. It applies to all compilation_units included in a partition. 4

Documentation Requirements

5/2 {*AI95-00434-01*} If a pragma Normalize_Scalars applies, the implementation shall document the implicit initial values for scalar subtypes, and shall identify each case in which such a value is used and is not an invalid representation.

5.a/2 **Documentation Requirement:** If a pragma Normalize_Scalars applies, the implicit initial values of scalar subtypes shall be documented. Such a value should be an invalid representation when possible; any cases when is it not shall be documented.

5.b **To be honest:** It's slightly inaccurate to say that the value is a representation, but the point should be clear anyway.

5.c **Discussion:** By providing a type with a size specification so that spare bits are present, it is possible to force an implementation of Normalize_Scalars to use an out of range value. This can be tested for by ensuring that Constraint_Error is raised. Similarly, for an unconstrained integer type, in which no spare bit is surely present, one can check that the initialization takes place to the value specified in the documentation of the implementation. For a floating point type, spare bits might not be available, but a range constraint can provide the ability to use an out of range value.

5.d If it is difficult to document the general rule for the implicit initial value, the implementation might choose instead to record the value on the object code listing or similar output produced during compilation.

Implementation Advice

6/2 {*AI95-00434-01*} Whenever possible, the implicit initial values for a scalar subtype should be an invalid representation (see 13.9.1).

6.a **Discussion:** When an out of range value is used for the initialization, it is likely that constraint checks will detect it. In addition, it can be detected by the Valid attribute.

6.b/2 This rule is included in the documentation requirements, and thus does not need a separate summary item.

7 NOTE 1 The initialization requirement applies to uninitialized scalar objects that are subcomponents of composite objects, to allocated objects, and to stand-alone objects. It also applies to scalar **out** parameters. Scalar subcomponents of composite **out** parameters are initialized to the corresponding part of the actual, by virtue of 6.4.1.

8 NOTE 2 The initialization requirement does not apply to a scalar for which pragma Import has been specified, since initialization of an imported object is performed solely by the foreign language environment (see B.1).

9/5 NOTE 3 {*AI12-0440-1*} The use of pragma Normalize_Scalars in conjunction with Pragma Restrictions(No_Exceptions) can result in erroneous execution (see H.4).

9.a **Discussion:** Since the effect of an access to an out of range value will often be to raise Constraint_Error, it is clear that suppressing the exception mechanism could result in erroneous execution. In particular, the assignment to an array, with the array index out of range, will result in a write to an arbitrary store location, having unpredictable effects.

H.2 Documentation of Implementation Decisions

Documentation Requirements

1/5 {*AI12-0439-1*} The implementation shall document the range of effects for each situation that the language rules identify as either a bounded error or as having an unspecified effect. If the implementation can constrain the effects of erroneous execution for a given construct, then it shall document such constraints. [The documentation may be provided either independently of any compilation unit or partition, or as part of an annotated listing for a given unit or partition. See also 1.1.3, and 1.1.2.]

1.a/2 *This paragraph was deleted.*

1.b/2 **Documentation Requirement:** The range of effects for each bounded error and each unspecified effect. If the effects of a given erroneous construct are constrained, the constraints shall be documented.

2 NOTE Among the situations to be documented are the conventions chosen for parameter passing, the methods used for the management of run-time storage, and the method used to evaluate numeric expressions if this involves extended range or extra precision.

2.a **Discussion:** Look up “unspecified” and “erroneous execution” in the index for a list of the cases.

The management of run-time storage is particularly important. For safety applications, it is often necessary to show that a program cannot raise Storage_Error, and for security applications that information cannot leak via the run-time system. Users are likely to prefer a simple storage model that can be easily validated. 2.b

The documentation could helpfully take into account that users may well adopt a subset to avoid some forms of erroneous execution, for instance, not using the abort statement, so that the effects of a partly completed assignment_statement do not have to be considered in the validation of a program (see 9.8). For this reason documentation linked to an actual compilation may be most useful. Similarly, an implementation may be able to take into account use of the Restrictions pragma. 2.c

H.3 Reviewable Object Code

Object code review and validation are supported by pragmas Reviewable and Inspection_Point. 1

H.3.1 Pragma Reviewable

This pragma directs the implementation to provide information to facilitate analysis and review of a program's object code, in particular to allow determination of execution time and storage usage and to identify the correspondence between the source and object programs. 1

Discussion: Since the purpose of this pragma is to provide information to the user, it is hard to objectively test for conformity. In practice, users want the information in an easily understood and convenient form, but neither of these properties can be easily measured. 1.a

Syntax

The form of a pragma Reviewable is as follows: 2

pragma Reviewable; 3

Post-Compilation Rules

Pragma Reviewable is a configuration pragma. It applies to all compilation_units included in a partition. 4

Implementation Requirements

The implementation shall provide the following information for any compilation unit to which such a pragma applies: 5

Discussion: The list of requirements can be checked for, even if issues like intelligibility are not addressed. 5.a

- Where compiler-generated runtime checks remain; 6

  Discussion: A constraint check which is implemented via a check on the upper and lower bound should clearly be indicated. If a check is implicit in the form of machine instructions used (such an overflow checking), this should also be covered by the documentation. It is particularly important to cover those checks which are not obvious from the source code, such as that for stack overflow. 6.a

- An identification of any construct with a language-defined check that is recognized prior to run time as certain to fail if executed (even if the generation of runtime checks has been suppressed); 7

  Discussion: In this case, if the compiler determines that a check must fail, the user should be informed of this. However, since it is not in general possible to know what the compiler will detect, it is not easy to test for this. In practice, it is thought that compilers claiming conformity to this Annex will perform significant optimizations and therefore *will* detect such situations. Of course, such events could well indicate a programmer error. 7.a

- {*AI95-00209-01*} For each read of a scalar object, an identification of the read as either “known to be initialized”, or “possibly uninitialized”, independent of whether pragma Normalize_Scalars applies; 8/2

  Discussion: This issue again raises the question as to what the compiler has determined. A lazy implementation could clearly mark all scalars as “possibly uninitialized”, but this would be very unhelpful to the user. It should be possible to analyze a range of scalar uses and note the percentage in each class. Note that an access marked “known to be initialized” does not imply that the value is in range, since the initialization could be from an (erroneous) call of unchecked conversion, or by means external to the Ada program. 8.a

9 • Where run-time support routines are implicitly invoked;

9.a **Discussion:** Validators will need to know the calls invoked in order to check for the correct functionality. For instance, for some safety applications, it may be necessary to ensure that certain sections of code can execute in a particular time.

10 • An object code listing, including:

11 • Machine instructions, with relative offsets;

11.a **Discussion:** The machine instructions should be in a format that is easily understood, such as the symbolic format of the assembler. The relative offsets are needed in numeric format, to check any alignment restrictions that the architecture might impose.

12 • Where each data object is stored during its lifetime;

12.a **Discussion:** This requirement implies that if the optimizer assigns a variable to a register, this needs to be evident.

13 • Correspondence with the source program, including an identification of the code produced per declaration and per statement.

13.a **Discussion:** This correspondence will be quite complex when extensive optimization is performed. In particular, address calculation to access some data structures could be moved from the actual access. However, when all the machine code arising from a statement or declaration is in one basic block, this must be indicated by the implementation.

14 • An identification of each construct for which the implementation detects the possibility of erroneous execution;

14.a **Discussion:** This requirement is quite vague. In general, it is hard for compilers to detect erroneous execution and therefore the requirement will be rarely invoked. However, if the pragma Suppress is used and the compiler can show that a predefined exception will be raised, then such an identification would be useful.

15 • For each subprogram, block, task, or other construct implemented by reserving and subsequently freeing an area on a run-time stack, an identification of the length of the fixed-size portion of the area and an indication of whether the non-fixed size portion is reserved on the stack or in a dynamically-managed storage region.

15.a **Discussion:** This requirement is vital for those requiring to show that the storage available to a program is sufficient. This is crucial in those cases in which the internal checks for stack overflow are suppressed (perhaps by **pragma** Restrictions(No_Exceptions)).

16 The implementation shall provide the following information for any partition to which the pragma applies:

17 • An object code listing of the entire partition, including initialization and finalization code as well as run-time system components, and with an identification of those instructions and data that will be relocated at load time;

17.a **Discussion:** The object code listing should enable a validator to estimate upper bounds for the time taken by critical parts of a program. Similarly, by an analysis of the entire partition, it should be possible to ensure that the storage requirements are suitably bounded, assuming that the partition was written in an appropriate manner.

18 • A description of the run-time model relevant to the partition.

18.a **Discussion:** For example, a description of the storage model is vital, since the Ada language does not explicitly define such a model.

18.1 The implementation shall provide control- and data-flow information, both within each compilation unit and across the compilation units of the partition.

18.b **Discussion:** This requirement is quite vague, since it is unclear what control and data flow information the compiler has produced. It is really a plea not to throw away information that could be useful to the validator. Note that the data flow information is relevant to the detection of "possibly uninitialized" objects referred to above.

Implementation Advice

19 The implementation should provide the above information in both a human-readable and machine-readable form, and should document the latter so as to ease further processing by automated tools.

Implementation Advice: The information produced by pragma Reviewable should be provided in both a human-readable and machine-readable form, and the latter form should be documented. 19.a/2

Object code listings should be provided both in a symbolic format and also in an appropriate numeric format (such as hexadecimal or octal). 20

Implementation Advice: Object code listings should be provided both in a symbolic format and in a numeric format. 20.a/2

Reason: This is to enable other tools to perform any analysis that the user needed to aid validation. The format should be in some agreed form. 20.b

NOTE The order of elaboration of library units will be documented even in the absence of pragma Reviewable (see 10.2). 21

Discussion: There might be some interactions between pragma Reviewable and compiler optimizations. For example, an implementation may disable some optimizations when pragma Reviewable is in force if it would be overly complicated to provide the detailed information to allow review of the optimized object code. See also pragma Optimize (2.8). 21.a

Wording Changes from Ada 95

{*AI95-00209-01*} The wording was clarified that pragma Reviewable applies to each read of an object, as it makes no sense to talk about the state of an object that will immediately be overwritten. 21.b/2

H.3.2 Pragma Inspection_Point

An occurrence of a pragma Inspection_Point identifies a set of objects each of whose values is to be available at the point(s) during program execution corresponding to the position of the pragma in the compilation unit. The purpose of such a pragma is to facilitate code validation. 1

Discussion: Inspection points are a high level equivalent of break points used by debuggers. 1.a

Syntax

The form of a pragma Inspection_Point is as follows: 2

pragma Inspection_Point[(*object*_name {, *object*_name})]; 3

Legality Rules

A pragma Inspection_Point is allowed wherever a declarative_item or statement is allowed. Each *object*_name shall statically denote the declaration of an object. 4

Discussion: The static denotation is required, since no dynamic evaluation of a name is involved in this pragma. 4.a

Static Semantics

{*8652/0093*} {*AI95-00207-01*} {*AI95-00434-01*} An *inspection point* is a point in the object code corresponding to the occurrence of a pragma Inspection_Point in the compilation unit. An object is *inspectable* at an inspection point if the corresponding pragma Inspection_Point either has an argument denoting that object, or has no arguments and the declaration of the object is visible at the inspection point. 5/2

Ramification: If a pragma Inspection_Point is in an in-lined subprogram, there might be numerous inspection points in the object code corresponding to the single occurrence of the pragma in the source; similar considerations apply if such a pragma is in a generic, or in a loop that has been "unrolled" by an optimizer. 5.a

{*8652/0093*} {*AI95-00207-01*} The short form of the pragma is a convenient shorthand for listing all objects which could be explicitly made inspectable by the long form of the pragma; thus only visible objects are made inspectable by it. Objects that are not visible at the point of the pragma are not made inspectable by the short form pragma. This is necessary so that implementations need not keep information about (or prevent optimizations on) a unit simply because some other unit *might* contain a short form Inspection_Point pragma. 5.a.1/1

Discussion: {*8652/0093*} {*AI95-00207-01*} If the short form of the pragma is used, then all visible objects are inspectable. This implies that global objects from other compilation units are inspectable. A good interactive debugging system could provide information similar to a post-mortem dump at such inspection points. The annex does 5.b/1

not require that any inspection facility is provided, merely that the information is available to understand the state of the machine at those points.

Dynamic Semantics

6 Execution of a pragma Inspection_Point has no effect.

6.a/2 **Discussion:** {*AI95-00114-01*} Although an inspection point has no (semantic) effect, the removal or adding of a new point could change the machine code generated by the compiler.

Implementation Requirements

7 Reaching an inspection point is an external interaction with respect to the values of the inspectable objects at that point (see 1.1.3).

7.a **Ramification:** The compiler is inhibited from moving an assignment to an inspectable variable past an inspection point for that variable. On the other hand, the evaluation of an expression that might raise an exception may be moved past an inspection point (see 11.6).

Documentation Requirements

8 For each inspection point, the implementation shall identify a mapping between each inspectable object and the machine resources (such as memory locations or registers) from which the object's value can be obtained.

8.a/2 *This paragraph was deleted.*

8.b/2 **Documentation Requirement:** For each inspection point, a mapping between each inspectable object and the machine resources where the object's value can be obtained shall be provided.

9/5 NOTE 1 {*AI95-00209-01*} {*AI12-0447-1*} Because reaching an inspection point is considered an external interaction relative to the values of the inspectable variables, the implementation cannot perform “dead store elimination” on the last assignment to such a variable prior to an inspection point. Thus an inspection point has the effect of an implicit read of each of its inspectable objects.

10 NOTE 2 Inspection points are useful in maintaining a correspondence between the state of the program in source code terms, and the machine state during the program's execution. Assertions about the values of program objects can be tested in machine terms at inspection points. Object code between inspection points can be processed by automated tools to verify programs mechanically.

10.a **Discussion:** Although it is not a requirement of the annex, it would be useful if the state of the stack and heap could be interrogated. This would allow users to check that a program did not have a `storage leak'.

11/5 NOTE 3 {*AI12-0447-1*} The identification of the mapping from source program objects to machine resources can be in the form of an annotated object listing, in human-readable or tool-processable form.

11.a **Discussion:** In principle, it is easy to check an implementation for this pragma, since one merely needs to check the content of objects against those values known from the source listing. In practice, one needs a tool similar to an interactive debugger to perform the check.

Wording Changes from Ada 95

11.b/2 {*8652/0093*} {*AI95-00207-01*} **Corrigendum:** Corrected the definition of the Inspection_Point pragma to apply to only variables visible at the point of the pragma. Otherwise, the compiler would have to assume that some other code somewhere could have a pragma Inspection_Point, preventing many optimizations (such as unused object elimination).

H.4 High Integrity Restrictions

1/3 {*AI05-0299-1*} This subclause defines restrictions that can be used with pragma Restrictions (see 13.12); these facilitate the demonstration of program correctness by allowing tailored versions of the run-time system.

1.a/3 **Discussion:** {*AI05-0005-1*} Note that the restrictions are absolute. If a partition has 100 library units and just one needs Unchecked_Conversion, then the pragma cannot be used to ensure the other 99 units do not use Unchecked_Conversion. Note also that these are restrictions on all Ada code within a partition, and therefore it might not be evident from the specification of a package whether a restriction can be imposed.

Static Semantics

This paragraph was deleted.{*AI95-00347-01*} {*AI95-00394-01*} 2/2

{*AI95-00394-01*} The following *restriction_*identifiers are language defined: 3/2

Tasking-related restriction: 4

No_Protected_Types 5
There are no declarations of protected types or protected objects.

Memory-management related restrictions: 6

No_Allocators 7
There are no occurrences of an allocator.

{*8652/0042*} {*AI95-00130*} No_Local_Allocators 8/1
Allocators are prohibited in subprograms, generic subprograms, tasks, and entry bodies.

Ramification: Thus allocators are permitted only in expressions whose evaluation can only be performed before the main subprogram is invoked. 8.a

This paragraph was deleted.{*8652/0042*} {*AI95-00130*} 8.b/1

{*AI05-0152-1*} {*AI05-0262-1*} No_Anonymous_Allocators 8.1/3
There are no allocators of anonymous access types.

{*AI05-0190-1*} No_Coextensions 8.2/3
There are no coextensions. See 3.10.2.

{*AI05-0190-1*} No_Access_Parameter_Allocators 8.3/3
Allocators are not permitted as the actual parameter to an access parameter. See 6.1.

This paragraph was deleted.{*AI95-00394-01*} 9/2

Immediate_Reclamation 10
Except for storage occupied by objects created by allocators and not deallocated via unchecked deallocation, any storage reserved at run time for an object is immediately reclaimed when the object no longer exists.

Discussion: Immediate reclamation would apply to storage created by the compiler, such as for a return value from a function whose size is not known at the call site. 10.a

Exception-related restriction: 11

{*AI12-0344-1*} No_Exceptions 12/5
Raise_statements and exception_handlers are not allowed. No language-defined runtime checks are generated; however, a runtime check performed automatically by the hardware is permitted. The callable entity associated with a procedural_iterator (see 5.5.3) is considered to not allow exit, independent of the value of its Allows_Exit aspect.

Discussion: This restriction mirrors a method of working that is quite common in the safety area. The programmer is required to show that exceptions cannot be raised. Then a simplified run-time system is used without exception handling. However, some hardware checks may still be enforced. If the software check would have failed, or if the hardware check actually fails, then the execution of the program is unpredictable. There are obvious dangers in this approach, but it is similar to programming at the assembler level. 12.a

Other restrictions: 13

No_Floating_Point 14
Uses of predefined floating point types and operations, and declarations of new floating point types, are not allowed.

Discussion: {*AI95-00114-01*} The intention is to avoid the use of floating point hardware at run time, but this is expressed in language terms. It is conceivable that floating point is used implicitly in some contexts, say fixed point type conversions of high accuracy. However, the Implementation Requirements below make it clear that the restriction 14.a/2

would apply to the “run-time system” and hence not be allowed. This restriction could be used to inform a compiler that a variant of the architecture is being used which does not have floating point instructions.

15 No_Fixed_Point
Uses of predefined fixed point types and operations, and declarations of new fixed point types, are not allowed.

15.a **Discussion:** This restriction would have the side effect of prohibiting the delay_relative_statement. As with the No_Floating_Point restriction, this might be used to avoid any question of rounding errors. Unless an Ada run-time is written in Ada, it seems hard to rule out implicit use of fixed point, since at the machine level, fixed point is virtually the same as integer arithmetic.

16/2 *This paragraph was deleted.*{*AI95-00394-01*}

17 No_Access_Subprograms
The declaration of access-to-subprogram types is not allowed.

17.a.1/2 **Discussion:** Most critical applications would require some restrictions or additional validation checks on uses of access-to-subprogram types. If the application does not require the functionality, then this restriction provides a means of ensuring the design requirement has been satisfied. The same applies to several of the following restrictions, and to restriction No_Dependence => Ada.Unchecked_Conversion.

18 No_Unchecked_Access
The Unchecked_Access attribute is not allowed.

19 No_Dispatch
Occurrences of T'Class are not allowed, for any (tagged) subtype T.

20/5 {*AI95-00285-01*} {*AI12-0318-1*} No_IO
Semantic dependence on any of the library units Sequential_IO, Direct_IO, Text_IO, Wide_Text_IO, Wide_Wide_Text_IO, Stream_IO, or Directories is not allowed.

20.a **Discussion:** Excluding the input-output facilities of an implementation may be needed in those environments which cannot support the supplied functionality. A program in such an environment is likely to require some low level facilities or a call on a non-Ada feature.

21 No_Delay Delay_Statements and semantic dependence on package Calendar are not allowed.

21.a **Ramification:** This implies that delay_alternatives in a select_statement are prohibited.

21.b The purpose of this restriction is to avoid the need for timing facilities within the run-time system.

22 No_Recursion
As part of the execution of a subprogram, the same subprogram is not invoked.

23 No_Reentrancy
During the execution of a subprogram by a task, no other task invokes the same subprogram.

23.1/5 {*AI12-0079-3*} No_Unspecified_Globals
No library-level entity shall have a Global aspect of Unspecified, either explicitly or by default. No library-level entity shall have a Global'Class aspect of Unspecified, explicitly or by default, if it is used as part of a dispatching call.

23.a/5 **Ramification:** Global'Class need not be specified on an operation if there are no dispatching calls to the operation, or if all of the dispatching calls are covered by dispatching_operation_specifiers for operations with such calls (see H.7).

23.2/5 {*AI12-0079-3*} {*AI12-0380-1*} No_Hidden_Indirect_Globals
When within a context where an applicable global aspect is neither Unspecified nor **in out all**, any execution within such a context does neither of the following:

23.3/5 - Update (or return a writable reference to) a variable that is reachable via a sequence of zero or more dereferences of access-to-object values from a parameter of a visibly access-to-constant type, from a part of a non-access-type formal parameter of mode **in** (after any **overriding** – see H.7), or from a global that has mode **in** or is not within the applicable global variable set, unless the initial dereference is of a part of a formal parameter or global that is visibly of an access-to-variable type;

- Read (or return a readable reference to) a variable that is reachable via a sequence of zero or more dereferences of access-to-object values from a global that is not within the applicable global variable set, unless the initial dereference is of a part of a formal parameter or global that is visibly of an access-to-object type. 23.4/5

Ramification: The above two rules specify that any hidden indirect references are covered by the global or formal parameter modes that apply, and are *not* subject to alternative paths of access (such as aliasing) that could result in conflicts. On the other hand, any visible access-to-object parts are allowed to designate objects that are accessible via other means, and side-effects on such objects are permitted if the value is visibly of an access-to-variable type. Such effects do not need to be covered by the applicable global aspect(s), but are rather for the caller to worry about. 23.b/5

For the purposes of the above rules: 23.5/5

- a part of an object is *visibly of an access type* if the type of the object is declared immediately within the visible part of a package specification, and at the point of declaration of the type the part is visible and of an access type; 23.6/5
- a function *returns a writable reference to V* if it returns a result with a part that is visibly of an access-to-variable type designating *V*; similarly, a function *returns a readable reference to V* if it returns a result with a part that is visibly of an access-to-constant type designating *V*; 23.7/5
- if an applicable global variable set includes a package name, and the collection of some pool-specific access type (see 7.6.1) is implicitly declared in a part of the declarative region of the package included within the global variable set, then all objects allocated from that collection are considered included within the global variable set. 23.8/5

The consequences of violating the No_Hidden_Indirect_Globals restriction is implementation-defined. Any aspects or other means for identifying such violations prior to or during execution are implementation-defined. 23.9/5

Implementation defined: The consequences of violating No_Hidden_Indirect_Globals. 23.b.1/5

Discussion: We do not make violations automatically erroneous, because if the implementation chooses to never fully trust it, there is nothing erroneous that can happen. If an implementation chooses to trust the restriction, and performs some optimization as a result of the restriction, the implementation would define such a violation as erroneous. Such an implementation might also endeavor to detect most violations, perhaps by providing additional aspects, thereby reducing the situations which result in erroneous execution. Implementations might detect some but not all violations of the restrictions. Implementations that completely ignore the restriction should treat the restriction as an unsupported capability of Annex H, “High Integrity Systems”. 23.c/5

Dynamic Semantics

{*AI12-0020-1*} {*AI12-0340-1*} The following *restriction_parameter*_identifier is language defined: 23.10/5

Max_Image_Length 23.11/5

Specifies the maximum length for the result of an Image, Wide_Image, or Wide_Wide_Image attribute. Violation of this restriction results in the raising of Program_Error at the point of the invocation of an image attribute.

Implementation Requirements

{*AI95-00394-01*} An implementation of this Annex shall support: 23.12/5

- the restrictions defined in this subclause; and 23.13/5
- {*AI05-0189-1*} the following restrictions defined in D.7: No_Task_Hierarchy, No_Abort_Statement, No_Implicit_Heap_Allocation, No_Standard_Allocators_After_Elaboration; and 23.14/5
- {*AI95-00347-01*} the **pragma** Profile(Ravenscar); and 23.15/5

23.d/2 **Discussion:** {*AI95-00347-01*} The reference to pragma Profile(Ravenscar) is intended to show that properly restricted tasking is appropriate for use in high integrity systems. The Ada 95 Annex seemed to suggest that tasking was inappropriate for such systems.

23.16/5 - the following uses of *restriction_parameter_*identifiers defined in D.7[, which are checked prior to program execution]:

23.17/5 - Max_Task_Entries => 0,

23.18/5 - Max_Asynchronous_Select_Nesting => 0, and

23.19/5 - Max_Tasks => 0.

23.20/5 {*AI12-0020-1*} {*AI12-0340-1*} If a Max_Image_Length restriction applies to any compilation unit in the partition, then for any subtype S, S'Image, S'Wide_Image, and S'Wide_Wide_Image shall be implemented within that partition without any dynamic allocation.

23.e/5 **Implementation Note:** {*AI12-0340-1*} {*AI12-0384-2*} This can be accomplished by using an object of the Text_Buffers.Bounded.Buffer_Type with the maximum characters as specified in the Max_Image_Length restriction, with a raise of Program_Error afterward if Text_Truncated (Buf) is True after the call on Put_Image (Buf, Arg).

24/5 {*AI05-0263-1*} {*AI05-0272-1*} {*AI12-0308-1*} If an implementation supports pragma Restrictions for a particular argument, then except for the restrictions No_Access_Subprograms, No_Unchecked_Access, No_Specification_of_Aspect, No_Use_of_Attribute, No_Use_of_Pragma, No_Dependence => Ada.Unchecked_Conversion, and No_Dependence => Ada.Unchecked_Deallocation, the associated restriction applies to the run-time system.

24.a **Reason:** Permission is granted for the run-time system to use the specified otherwise-restricted features, since the use of these features may simplify the run-time system by allowing more of it to be written in Ada.

24.b **Discussion:** The restrictions that are applied to the partition are also applied to the run-time system. For example, if No_Floating_Point is specified, then an implementation that uses floating point for implementing the delay statement (say) would require that No_Floating_Point is only used in conjunction with No_Delay. It is clearly important that restrictions are effective so that Max_Tasks=0 does imply that tasking is not used, even implicitly (for input-output, say).

24.c An implementation of tasking could be produced based upon a run-time system written in Ada in which the rendezvous was controlled by protected types. In this case, No_Protected_Types could only be used in conjunction with Max_Task_Entries=0. Other implementation dependencies could be envisaged.

24.d If the run-time system is not written in Ada, then the wording needs to be applied in an appropriate fashion.

Documentation Requirements

25 If a pragma Restrictions(No_Exceptions) is specified, the implementation shall document the effects of all constructs where language-defined checks are still performed automatically (for example, an overflow check performed by the processor).

25.a/2 *This paragraph was deleted.*

25.b/2 **Documentation Requirement:** If a pragma Restrictions(No_Exceptions) is specified, the effects of all constructs where language-defined checks are still performed.

25.c/2 **Discussion:** {*AI95-00114-01*} The documentation requirements here are quite difficult to satisfy. One method is to review the object code generated and determine the checks that are still present, either explicitly, or implicitly within the architecture. As another example from that of overflow, consider the question of dereferencing a null pointer. This could be undertaken by a memory access trap when checks are performed. When checks are suppressed via the argument No_Exceptions, it would not be necessary to have the memory access trap mechanism enabled.

Erroneous Execution

26 Program execution is erroneous if pragma Restrictions(No_Exceptions) has been specified and the conditions arise under which a generated language-defined runtime check would fail.

26.a **Discussion:** The situation here is very similar to the application of pragma Suppress. Since users are removing some of the protection the language provides, they had better be careful!

Program execution is erroneous if pragma Restrictions(No_Recursion) has been specified and a subprogram is invoked as part of its own execution, or if pragma Restrictions(No_Reentrancy) has been specified and during the execution of a subprogram by a task, another task invokes the same subprogram. 27

Discussion: {*AI05-0005-1*} In practice, many implementations might not exploit the absence of recursion or need for reentrancy, in which case the program execution would be unaffected by the use of recursion or reentrancy, even though the program is still formally erroneous. 27.a/3

This paragraph was deleted. 27.b/2

NOTE {*AI95-00394-01*} {*AI12-0440-1*} Uses of *restriction_parameter_*identifier No_Dependence defined in 13.12.1: No_Dependence => Ada.Unchecked_Deallocation and No_Dependence => Ada.Unchecked_Conversion can be appropriate for high-integrity systems. Other uses of No_Dependence can also be appropriate for high-integrity systems. 28/5

Discussion: The specific mention of these two uses is meant to replace the identifiers now banished to J.13, "Dependence Restriction Identifiers". 28.a/2

Restriction No_Dependence => Ada.Unchecked_Deallocation would be useful in those contexts in which heap storage is needed on program start-up, but need not be increased subsequently. The danger of a dangling pointer can therefore be avoided. 28.b/2

Extensions to Ada 95

{*8652/0042*} {*AI95-00130-01*} No_Local_Allocators no longer prohibits generic instantiations. 28.c/2

Wording Changes from Ada 95

{*AI95-00285-01*} Wide_Wide_Text_IO (which is new) is added to the No_IO restriction. 28.d/2

{*AI95-00347-01*} {*AI05-0299-1*} The title of this subclause was changed to match the change to the Annex title. Pragma Profile(Ravenscar) is part of this annex. 28.e/3

{*AI95-00394-01*} Restriction No_Dependence is used instead of special *restriction_*identifiers. The old names are banished to Obsolescent Features (see J.13). 28.f/2

{*AI95-00394-01*} The bizarre wording "apply in this Annex" (which no one quite can explain the meaning of) is banished. 28.g/2

Extensions to Ada 2005

{*AI05-0152-1*} {*AI05-0190-1*} Restrictions No_Anonymous_Allocators, No_Coextensions, and No_Access_Parameter_Allocators are new. 28.h/3

Wording Changes from Ada 2005

{*AI05-0189-1*} New restriction No_Standard_Allocators_After_Elaboration is added to the list of restrictions that are required by this annex. 28.i/3

{*AI05-0263-1*} **Correction:** Ada 2005 restriction No_Dependence is added where needed (this was missed in Ada 2005). 28.j/3

{*AI05-0272-1*} Restrictions against individual aspects, pragmas, and attributes do not apply to the run-time system, in order that an implementation can use whatever aspects, pragmas, and attributes are needed to do the job. For instance, attempting to write a run-time system for Linux that does not use the Import aspect would be very difficult and probably is not what the user is trying to prevent anyway. 28.k/3

Incompatibilities With Ada 2012

{*AI12-0318-1*} **Correction:** Restriction No_IO now excludes use of Ada.Directories. If a program using No_IO used Ada.Directories, it would be legal in Ada 2012 and illegal in Ada 2022. However, given the role of Ada.Directories as a support package for the other packages that are excluded by No_IO, it seems unlikely that any use of the restriction would use this package (and it's possible that implementations wouldn't support its use with No_IO anyway). 28.l/5

Extensions to Ada 2012

{*AI12-0020-1*} Restriction Max_Image_Length is new. 28.m/5

{*AI12-0079-3*} Restrictions No_Unspecified_Globals and No_Hidden_Indirect_Globals are new. 28.n/5

H.4.1 Aspect No_Controlled_Parts

Static Semantics

1/5 {*AI12-0256-1*} {*AI12-0403-1*} For a type, the following type-related, operational aspect may be specified:

2/5 No_Controlled_Parts

The type of this aspect is Boolean. If True, the type and any descendants shall not have any controlled parts. If specified, the value of the expression shall be static. If not specified, the value of this aspect is False.

2.a/5 **Aspect Description for No_Controlled_Parts:** A specification that a type and its descendants do not have controlled parts.

3/5 {*AI12-0256-1*} The No_Controlled_Parts aspect is nonoverridable (see 13.1.1).

3.a/5 **Discussion:** {*AI12-0407-1*} Since this is a Boolean-valued aspect, the blanket restrictions defined by 13.1.1 apply to the specification of Boolean-valued aspects on descendants of types with such aspects. But we still need rules about inheritance from progenitors and about hiding the aspect; it would be too painful to repeat those rules here (and have future maintenance fixes not get applied to this aspect).

Legality Rules

4/5 {*AI12-0256-1*} {*AI12-0407-1*} If No_Controlled_Parts is True for a type, no component of the type shall have a controlled part nor shall the type itself be controlled. For the purposes of this rule, a type has a controlled part if its full type has a controlled part; this is applied recursively. In addition to the places where Legality Rules normally apply (see 12.3), this rule also applies in the private part of an instance of a generic unit.

4.a/5 **Discussion:** {*AI12-0407-1*} This check breaks privacy by looking at the full definition of all of the types involved. This is more like a representation aspect than an operational aspect, but representation aspects are not allowed on partial views and we need this aspect to be visible to clients.

5/5 {*AI12-0256-1*} {*AI12-0407-1*} When enforcing the above rule within a generic body *G* or within the body of a generic unit declared within the declarative region of generic unit *G*, a generic formal private type of *G* and a generic formal derived type of *G* whose ancestor is a tagged type whose No_Controlled_Parts aspect is False are considered to have a controlled part.

5.a/5 **Reason:** This is a typical generic assume-the-worst rule.

5.b/5 **To be honest:** {*AI12-0407-1*} If the ancestor of the generic derived type is class-wide, the aspect in question belongs to the specific type associated with the class-wide type.

Extensions to Ada 2012

5.c/5 {*AI12-0256-1*} {*AI12-0407-1*} Aspect No_Controlled_Parts is new.

H.5 Pragma Detect_Blocking

1/5 {*AI95-00305-01*} {*AI12-0267-1*} The following pragma requires an implementation to detect potentially blocking operations during the execution of a protected operation or a parallel construct.

Syntax

2/2 {*AI95-00305-01*} The form of a pragma Detect_Blocking is as follows:

3/2 **pragma** Detect_Blocking;

Post-Compilation Rules

4/2 {*AI95-00305-01*} A pragma Detect_Blocking is a configuration pragma.

Dynamic Semantics

{*AI95-00305-01*} {*AI12-0247-1*} {*AI12-0267-1*} An implementation is required to detect a potentially blocking operation that occurs during the execution of a protected operation or a parallel construct defined within a compilation unit to which the pragma applies, and to raise Program_Error (see 9.5). 5/5

Implementation Permissions

{*AI95-00305-01*} {*AI12-0267-1*} An implementation is allowed to reject a compilation_unit to which a pragma Detect_Blocking applies if a potentially blocking operation is present directly within an entry_body, the body of a protected subprogram, or a parallel construct occurring within the compilation unit. 6/5

NOTE {*AI95-00305-01*} {*AI12-0442-1*} An operation that causes a task to be blocked within a foreign language domain is not defined to be potentially blocking, and is unlikely to be detected. 7/5

Extensions to Ada 95

{*AI95-00305-01*} Pragma Detect_Blocking is new. 7.a/2

Extensions to Ada 2012

{*AI12-0267-1*} Pragma Detect_Blocking now applies to parallel constructs as well as protected actions. 7.b/5

H.6 Pragma Partition_Elaboration_Policy

{*AI95-00265-01*} {*AI05-0299-1*} This subclause defines a pragma for user control over elaboration policy. 1/3

Syntax

{*AI95-00265-01*} The form of a pragma Partition_Elaboration_Policy is as follows: 2/2

pragma Partition_Elaboration_Policy (*policy*_identifier); 3/2

The *policy*_identifier shall be either Sequential, Concurrent or an implementation-defined identifier. 4/2

Implementation defined: Implementation-defined *policy*_identifiers allowed in a pragma Partition_Elaboration_Policy. 4.a/2

Ramification: Note that the Ravenscar profile (see D.13) has nothing to say about which Partition_Elaboration_Policy is used. This was intentionally omitted from the profile, as there was no agreement as to whether the Sequential policy should be required for Ravenscar programs. As such it was defined separately. 4.b/3

Post-Compilation Rules

{*AI95-00265-01*} A pragma Partition_Elaboration_Policy is a configuration pragma. It specifies the elaboration policy for a partition. At most one elaboration policy shall be specified for a partition. 5/2

{*AI95-00265-01*} {*AI05-0264-1*} If the Sequential policy is specified for a partition, then pragma Restrictions (No_Task_Hierarchy) shall also be specified for the partition. 6/3

Dynamic Semantics

{*AI95-00265-01*} Notwithstanding what this document says elsewhere, this pragma allows partition elaboration rules concerning task activation and interrupt attachment to be changed. If the *policy*_identifier is Concurrent, or if there is no pragma Partition_Elaboration_Policy defined for the partition, then the rules defined elsewhere in this Reference Manual apply. 7/2

{*AI95-00265-01*} {*AI95-00421-01*} If the partition elaboration policy is Sequential, then task activation and interrupt attachment are performed in the following sequence of steps: 8/2

9/2 - The activation of all library-level tasks and the attachment of interrupt handlers are deferred until all library units are elaborated.

10/2 - The interrupt handlers are attached by the environment task.

11/2 - The environment task is suspended while the library-level tasks are activated.

12/2 - The environment task executes the main subprogram (if any) concurrently with these executing tasks.

13/2 {*AI95-00265-01*} {*AI95-00421-01*} If several dynamic interrupt handler attachments for the same interrupt are deferred, then the most recent call of Attach_Handler or Exchange_Handler determines which handler is attached.

14/2 {*AI95-00265-01*} {*AI95-00421-01*} If any deferred task activation fails, Tasking_Error is raised at the beginning of the sequence of statements of the body of the environment task prior to calling the main subprogram.

Implementation Advice

15/3 {*AI95-00265-01*} {*AI05-0264-1*} If the partition elaboration policy is Sequential and the Environment task becomes permanently blocked during elaboration, then the partition is deadlocked and it is recommended that the partition be immediately terminated.

15.a/3 **Implementation Advice:** If the partition elaboration policy is Sequential and the Environment task becomes permanently blocked during elaboration, then the partition should be immediately terminated.

Implementation Permissions

16/3 {*AI95-00265-01*} {*AI05-0264-1*} If the partition elaboration policy is Sequential and any task activation fails, then an implementation may immediately terminate the active partition to mitigate the hazard posed by continuing to execute with a subset of the tasks being active.

17/5 NOTE {*AI95-00421-01*} {*AI12-0440-1*} If any deferred task activation fails, the environment task is unable to handle the Tasking_Error exception and completes immediately. By contrast, if the partition elaboration policy is Concurrent, then this exception can be handled within a library unit.

Extensions to Ada 95

17.a/2 {*AI95-00265-01*} {*AI95-00421-01*} Pragma Partition_Elaboration_Policy is new.

H.7 Extensions to Global and Global'Class Aspects

1/5 {*AI12-0079-3*} In addition to the entities specified in 6.1.2, the Global aspect may be specified for a subtype (including a formal subtype), formal package, formal subprogram, and formal object of an anonymous access-to-subprogram type.

Syntax

2/5 {*AI12-0079-3*} {*AI12-0380-1*} The following additional syntax is provided to override the mode of a formal parameter to reflect indirect effects on variables reachable from the formal parameter by one or more access-value dereferences:

3/5
```
extended_global_mode ::=
   overriding basic_global_mode
```

Name Resolution Rules

4/5 {*AI12-0079-3*} The *object_*name that is associated with an **overriding** mode shall resolve to statically denote a formal object, or a formal parameter of the associated entity.

Static Semantics

{*AI12-0079-3*} The presence of the reserved word **overriding** in a global mode indicates that the specification is overriding the mode of a formal parameter with another mode to reflect the overall effect of an invocation of the callable entity on the state associated with the corresponding actual parameter. 5/5

{*AI12-0380-1*} [As described in 6.1.2, the following rules are defined in terms of operations that are performed by or on behalf of an entity.] 6/5

{*AI12-0079-3*} {*AI12-0431-1*} {*AI12-0439-1*} The Global aspect for a subtype identifies the global variables that can be referenced during default initialization, adjustment as part of assignment, finalization of an object of the subtype, or conversion to the subtype, including the evaluation of any assertion expressions that apply. If not specified for the first subtype of a derived type, the aspect defaults to that of the ancestor subtype; if not specified for a nonderived composite first subtype the aspect defaults to that of the enclosing library unit; if not specified for a nonderived elementary first subtype (or scalar base subtype), the aspect defaults to **null** in the absence of a predicate (or when the predicate is statically True), and to that of the enclosing library unit otherwise. If not specified for a nonfirst subtype *S*, the Global aspect defaults to that of the subtype identified in the subtype_indication defining *S*. 7/5

{*AI12-0079-3*} The Global'Class aspect may be specified for the first subtype of a tagged type *T*, indicating an upper bound on the Global aspect of any descendant of *T*. If not specified, it defaults to Unspecified. 8/5

Legality Rules

{*AI12-0079-3*} For a tagged subtype *T*, each mode of its Global aspect shall identify a subset of the variables identified either by the corresponding mode, or by the **in out** mode, of the Global'Class aspect of the first subtype of any ancestor of *T*. 9/5

Extensions to Ada 2012

{*AI12-0079-3*} {*AI12-0380-1*} These extensions to the Global aspect are new. 9.a/5

H.7.1 The Use_Formal and Dispatching Aspects

{*AI12-0380-1*} The Use_Formal and Dispatching aspects are provided to more precisely describe the use of generic formal parameters and dispatching calls within the execution of an operation, enabling more precise checking of conformance with the Nonblocking and global aspects that apply at the point of invocation of the operation. 1/5

{*AI12-0079-3*} {*AI12-0380-1*} For any declaration within a generic unit for which a global or Nonblocking aspect may be specified, other than a generic_formal_parameter_declaration, the following aspect may be specified to indicate which generic formal parameters are *used* by the associated entity: 2/5

{*AI12-0380-1*} Use_Formal 3/5

The aspect is specified with a formal_parameter_set, with the following form:

Aspect Description for Use_Formal: Generic formal parameters used in the implementation of an entity. 3.a/5

```
formal_parameter_set ::=                                                    4/5
   formal_group_designator
 | formal_parameter_name
 | (formal_parameter_name{, formal_parameter_name})

formal_group_designator ::= null | all                                      5/5

formal_parameter_name ::=                                                   6/5
   formal_subtype_mark
```

| *formal_subprogram_*name
| *formal_access_to_subprogram_object_*name

7/5 {*AI12-0079-3*} {*AI12-0380-1*} For any declaration for which a global or Nonblocking aspect may be specified, other than for a library package, a generic library package, or a generic formal, the following aspect may be specified:

8/5 {*AI12-0380-1*} Dispatching

The aspect is specified with a dispatching_operation_set, with the following form:

8.a/5 **Aspect Description for Dispatching:** Generic formal parameters used in the implementation of an entity.

9/5 dispatching_operation_set ::=
dispatching_operation_specifier
| (dispatching_operation_specifier{, dispatching_operation_specifier})

10/5 dispatching_operation_specifier ::=
*dispatching_operation_*name (*object_*name)

Name Resolution Rules

11/5 {*AI12-0380-1*} A formal_parameter_name in a Use_Formal aspect shall resolve to statically denote a formal subtype, a formal subprogram, or a formal object of an anonymous access-to-subprogram type[of an enclosing generic unit or visible formal package].

12/5 {*AI12-0380-1*} The *object_*name of a dispatching_operation_specifier shall resolve to statically name an object (including possibly a formal parameter) of a tagged class-wide type *T*'Class, or of an access type designating a tagged class-wide type *T*'Class; the *dispatching_operation_*name of the dispatching_operation_specifier shall resolve to statically denote a dispatching operation associated with *T*.

Static Semantics

13/5 {*AI12-0380-1*} {*AI12-0439-1*} The *formal parameter set* is identified by a set of formal_parameter_names. Alternatively, the reserved word **null** may be used to indicate none of the generic formal parameters, or **all** to indicate all of the generic formal parameters, of any enclosing generic unit (or visible formal package) can be used within the execution of the operation. If there is no formal parameter set specified for an entity declared within a generic unit, it defaults to **all**.

14/5 {*AI12-0380-1*} {*AI12-0404-1*} {*AI12-0444-1*} The *dispatching operation set* is identified by a set of dispatching_operation_specifiers. It indicates that the Nonblocking and global effects of dispatching calls that match one of the specifiers, rather than being accounted for by the Nonblocking or global aspect, are instead to be accounted for by the invoker of the operation. A dispatching call matches a dispatching_operation_specifier if the name or prefix of the call statically denotes the same operation(s) as that of the dispatching_operation_specifier, and at least one of the objects controlling the call is denoted by, or designated by, a name that statically names the same object as that denoted by the *object_*name of the dispatching_operation_specifier.

14.a/5 **Ramification:** The object "controlling the call" is not necessarily a controlling parameter of the call if the call is a function with a controlling result or has parameters that is such a function. It is one of the objects that provide the dispatching tag used for the call; that could, for example, be a parameter of a function used as a parameter to the call, or an object being assigned to, or a parameter of an enclosing call.

15/5 {*AI12-0380-1*} {*AI12-0404-1*} In the absence of any dispatching_operation_specifiers, or if none of them match a dispatching call *C* within an operation *P*, Nonblocking and global aspects checks are performed at the point of the call *C* within *P* using the Nonblocking and Global'Class aspects that apply to the dispatching operation named in call *C*. If there is a match, any global access or potential blocking within the subprogram body invoked by the call *C* is ignored at the point of call within *P*. Instead, when

the operation *P* itself is invoked, Nonblocking and global aspect checks are performed presuming each named dispatching operation is called at least once (with the named object controlling the call), but similarly ignoring those dispatching calls that would match a dispatching_operation_specifier applicable at the point of invocation of *P*.

Legality Rules

{*AI12-0380-1*} Within an operation to which a Use_Formal aspect applies, if the formal parameter set is anything but **all**, then the only generic formal subtypes that may be used, the only formal subprograms that may be called, and the only formal objects of an anonymous access-to-subprogram type that may be dereferenced as part of a call or passed as the actual for an access parameter, are those included in the formal parameter set. 16/5

{*AI12-0380-1*} When an operation (or instance thereof) to which a Use_Formal aspect applies is invoked, Nonblocking and global aspect checks are performed presuming each generic formal parameter (or corresponding actual parameter) of the formal parameter set is used at least once. 17/5

Examples

{*AI12-0430-1*} *An example of use of the Dispatching aspect:* 18/5

```
procedure My_Write(  --  see 13.13.2                                    19/5
   Stream : not null access Ada.Streams.Root_Stream_Type'Class;
   Item   : My_Integer'Base)
   with Dispatching => Write(Stream);
for My_Integer'Write use My_Write;
```

{*AI12-0430-1*} *For examples of use of the Use_Formal aspect, see the Element functions of Hashed_Sets in A.18.8.* 20/5

Extensions to Ada 2012

{*AI12-0079-3*} The aspects Use_Formal and Dispatching are new. 20.a/5

Annex J
(normative)
Obsolescent Features

{*AI95-00368-01*} [This Annex contains descriptions of features of the language whose functionality is largely redundant with other features defined by this Reference Manual. Use of these features is not recommended in newly written programs. Use of these features can be prevented by using pragma Restrictions (No_Obsolescent_Features), see 13.12.1.] 1/2

Ramification: These features are still part of the language, and have to be implemented by conforming implementations. The primary reason for putting these descriptions here is to get redundant features out of the way of most readers. The designers of the next version of Ada will have to assess whether or not it makes sense to drop these features from the language. 1.a

Wording Changes from Ada 83

The following features have been removed from the language, rather than declared to be obsolescent: 1.b

- The package Low_Level_IO (see A.6). 1.c
- The Epsilon, Mantissa, Emax, Small, Large, Safe_Emax, Safe_Small, and Safe_Large attributes of floating point types (see A.5.3). 1.d
- *This paragraph was deleted.*{*AI95-00284-02*} 1.e/2
- The pragmas System_Name, Storage_Unit, and Memory_Size (see 13.7). 1.f
- The pragma Shared (see C.6). 1.g

Implementations can continue to support the above features for upward compatibility. 1.h

Wording Changes from Ada 95

{*AI95-00368-01*} A mention of the No_Obsolescent_Features restriction was added. 1.i/2

Wording Changes from Ada 2005

{*AI05-0229-1*} Pragma Controlled has been removed from the language, rather than declared to be obsolescent. No existing implementation gives it any effect. An implementation could continue to support the pragma as an implementation-defined pragma for upward compatibility. 1.j/3

J.1 Renamings of Library Units

Static Semantics

The following library_unit_renaming_declarations exist: 1

```
with Ada.Unchecked_Conversion;                                                    2
generic function Unchecked_Conversion renames Ada.Unchecked_Conversion;

with Ada.Unchecked_Deallocation;                                                  3
generic procedure Unchecked_Deallocation renames Ada.Unchecked_Deallocation;

with Ada.Sequential_IO;                                                           4
generic package Sequential_IO renames Ada.Sequential_IO;

with Ada.Direct_IO;                                                               5
generic package Direct_IO renames Ada.Direct_IO;

with Ada.Text_IO;                                                                 6
package Text_IO renames Ada.Text_IO;

with Ada.IO_Exceptions;                                                           7
package IO_Exceptions renames Ada.IO_Exceptions;

with Ada.Calendar;                                                                8
package Calendar renames Ada.Calendar;
```

9
```
with System.Machine_Code;
package Machine_Code renames System.Machine_Code; -- If supported.
```

9.a/3 **Discussion:** {*AI05-0004-1*} These library units correspond to those declared in Ada 83, which did not have the child unit concept or the parent package Ada.

Implementation Requirements

10 The implementation shall allow the user to replace these renamings.

J.2 Allowed Replacements of Characters

Syntax

1 The following replacements are allowed for the vertical line, number sign, and quotation mark characters:

2 • A vertical line character (|) can be replaced by an exclamation mark (!) where used as a delimiter.

3 • The number sign characters (#) of a based_literal can be replaced by colons (:) provided that the replacement is done for both occurrences.

3.a/2 **To be honest:** {*AI95-00285-01*} The intent is that such a replacement works in the Value, Wide_Value, and Wide_Wide_Value attributes, and in the Get procedures of Text_IO (and Wide_Text_IO and Wide_Wide_Text_IO as well)}, so that things like “16:.123:” is acceptable.

4 • The quotation marks (") used as string brackets at both ends of a string literal can be replaced by percent signs (%) provided that the enclosed sequence of characters contains no quotation mark, and provided that both string brackets are replaced. Any percent sign within the sequence of characters shall then be doubled and each such doubled percent sign is interpreted as a single percent sign character value.

5 These replacements do not change the meaning of the program.

5.a **Reason:** The original purpose of this feature was to support hardware (for example, teletype machines) that has long been obsolete. The feature is no longer necessary for that reason. Another use of the feature has been to replace the vertical line character (|) when using certain hardware that treats that character as a (non-English) letter. The feature is no longer necessary for that reason, either, since Ada 95 has full support for international character sets. Therefore, we believe this feature is no longer necessary.

5.b Users of equipment that still uses | to represent a letter will continue to do so. Perhaps by next the time Ada is revised, such equipment will no longer be in use.

5.c Note that it was never legal to use this feature as a convenient method of including double quotes in a string without doubling them — the string literal:

5.d
```
%"This is quoted."%
```

5.e/3 {*AI05-0248-1*} is not legal in Ada (and never was legal). One has to write:

5.f
```
"""This is quoted."""
```

J.3 Reduced Accuracy Subtypes

1 A digits_constraint may be used to define a floating point subtype with a new value for its requested decimal precision, as reflected by its Digits attribute. Similarly, a delta_constraint may be used to define an ordinary fixed point subtype with a new value for its *delta*, as reflected by its Delta attribute.

1.a **Discussion:** It might be more direct to make these attributes specifiable via an attribute_definition_clause, and eliminate the syntax for these _constraints.

Syntax

2/4 {*AI12-0152-1*} delta_constraint ::= **delta** *static*_simple_expression [range_constraint]

Name Resolution Rules

{*AI12-0152-1*} The simple_expression of a delta_constraint is expected to be of any real type. 3/4

Legality Rules

{*AI12-0152-1*} The simple_expression of a delta_constraint shall be static. 4/4

For a subtype_indication with a delta_constraint, the subtype_mark shall denote an ordinary fixed point subtype. 5

For a subtype_indication with a digits_constraint, the subtype_mark shall denote either a decimal fixed point subtype or a floating point subtype (notwithstanding the rule given in 3.5.9 that only allows a decimal fixed point subtype). 6

This paragraph was deleted.{*AI95-00114-01*} 6.a/2

Static Semantics

{*AI12-0152-1*} A subtype_indication with a subtype_mark that denotes an ordinary fixed point subtype and a delta_constraint defines an ordinary fixed point subtype with a *delta* given by the value of the simple_expression of the delta_constraint. If the delta_constraint includes a range_constraint, then the ordinary fixed point subtype is constrained by the range_constraint. 7/4

{*AI12-0152-1*} A subtype_indication with a subtype_mark that denotes a floating point subtype and a digits_constraint defines a floating point subtype with a requested decimal precision (as reflected by its Digits attribute) given by the value of the simple_expression of the digits_constraint. If the digits_constraint includes a range_constraint, then the floating point subtype is constrained by the range_constraint. 8/4

Dynamic Semantics

{*AI12-0152-1*} A delta_constraint is *compatible* with an ordinary fixed point subtype if the value of the simple_expression is no less than the *delta* of the subtype, and the range_constraint, if any, is compatible with the subtype. 9/4

{*AI12-0152-1*} A digits_constraint is *compatible* with a floating point subtype if the value of the simple_expression is no greater than the requested decimal precision of the subtype, and the range_constraint, if any, is compatible with the subtype. 10/4

The elaboration of a delta_constraint consists of the elaboration of the range_constraint, if any. 11

Reason: A numeric subtype is considered “constrained” only if a range constraint applies to it. The only effect of a digits_constraint or a delta_constraint without a range_constraint is to specify the value of the corresponding Digits or Delta attribute in the new subtype. The set of values of the subtype is not “constrained” in any way by such _constraints. 11.a

Wording Changes from Ada 83

In Ada 83, a delta_constraint is called a fixed_point_constraint, and a digits_constraint is called a floating_point_constraint. We have adopted other terms because digits_constraints apply primarily to decimal fixed point types now (they apply to floating point types only as an obsolescent feature). 11.b

Wording Changes from Ada 2012

{*AI12-0152-1*} **Corrigendum:** Changed the syntax so that the value following **delta** in a delta_constraint is a simple_expression. This is compatible as any expressions that would require extra parentheses are already illegal. The change is necessary to eliminate syntax ambguities in derived_type_definitions. The similar change for digits_constraint is documented in 3.5.9. 11.c/4

J.4 The Constrained Attribute

Static Semantics

1 For every private subtype S, the following attribute is defined:

1.a **Discussion:** This includes generic formal private subtypes.

2 S'Constrained

Yields the value False if S denotes an unconstrained nonformal private subtype with discriminants; also yields the value False if S denotes a generic formal private subtype, and the associated actual subtype is either an unconstrained subtype with discriminants or an unconstrained array subtype; yields the value True otherwise. The value of this attribute is of the predefined subtype Boolean.

2.a **Reason:** Because Ada 95 has unknown_discriminant_parts, the Constrained attribute of private subtypes is obsolete. This is fortunate, since its Ada 83 definition was confusing, as explained below. Because this attribute is obsolete, we do not bother to extend its definition to private extensions.

2.b The Constrained attribute of an object is *not* obsolete.

2.c Note well: S'Constrained matches the Ada 95 definition of "constrained" only for composite subtypes. For elementary subtypes, S'Constrained is always true, whether or not S is constrained. (The Constrained attribute of an object does not have this problem, as it is only defined for objects of a discriminated type.) So one should think of its designator as being 'Constrained_Or_Elementary.

J.5 ASCII

Static Semantics

1 The following declaration exists in the declaration of package Standard:

2
```
package ASCII is
```

3
```
   -- Control characters:
```

4
```
   NUL    : constant Character := nul;    SOH    : constant Character := soh;
   STX    : constant Character := stx;    ETX    : constant Character := etx;
   EOT    : constant Character := eot;    ENQ    : constant Character := enq;
   ACK    : constant Character := ack;    BEL    : constant Character := bel;
   BS     : constant Character := bs;     HT     : constant Character := ht;
   LF     : constant Character := lf;     VT     : constant Character := vt;
   FF     : constant Character := ff;     CR     : constant Character := cr;
   SO     : constant Character := so;     SI     : constant Character := si;
   DLE    : constant Character := dle;    DC1    : constant Character := dc1;
   DC2    : constant Character := dc2;    DC3    : constant Character := dc3;
   DC4    : constant Character := dc4;    NAK    : constant Character := nak;
   SYN    : constant Character := syn;    ETB    : constant Character := etb;
   CAN    : constant Character := can;    EM     : constant Character := em;
   SUB    : constant Character := sub;    ESC    : constant Character := esc;
   FS     : constant Character := fs;     GS     : constant Character := gs;
   RS     : constant Character := rs;     US     : constant Character := us;
   DEL    : constant Character := del;
```

5
```
   -- Other characters:
```

6
```
   Exclam    : constant Character:= '!'; Quotation : constant Character:= '"';
   Sharp     : constant Character:= '#'; Dollar    : constant Character:= '$';
   Percent   : constant Character:= '%'; Ampersand : constant Character:= '&';
   Colon     : constant Character:= ':'; Semicolon : constant Character:= ';';
   Query     : constant Character:= '?'; At_Sign   : constant Character:= '@';
   L_Bracket: constant Character:= '['; Back_Slash: constant Character:= '\';
   R_Bracket: constant Character:= ']'; Circumflex: constant Character:= '^';
   Underline: constant Character:= '_'; Grave     : constant Character:= '`';
   L_Brace   : constant Character:= '{'; Bar       : constant Character:= '|';
   R_Brace   : constant Character:= '}'; Tilde     : constant Character:= '~';
```

```
   -- Lower case letters:
   LC_A: constant Character:= 'a';
   ...
   LC_Z: constant Character:= 'z';
end ASCII;
```

J.6 Numeric_Error

Static Semantics

The following declaration exists in the declaration of package Standard:

```
Numeric_Error : exception renames Constraint_Error;
```

Discussion: This is true even though it is not shown in A.1.

Reason: In Ada 83, it was unclear which situations should raise Numeric_Error, and which should raise Constraint_Error. The permissions of RM83-11.6 could often be used to allow the implementation to raise Constraint_Error in a situation where one would normally expect Numeric_Error. To avoid this confusion, all situations that raise Numeric_Error in Ada 83 are changed to raise Constraint_Error in Ada 95. Numeric_Error is changed to be a renaming of Constraint_Error to avoid most of the upward compatibilities associated with this change.

In new code, Constraint_Error should be used instead of Numeric_Error.

J.7 At Clauses

Syntax

at_clause ::= **for** direct_name **use at** expression;

Static Semantics

An at_clause of the form "for *x* use at *y*;" is equivalent to an attribute_definition_clause of the form "for *x*'Address use *y*;".

Reason: The preferred syntax for specifying the address of an entity is an attribute_definition_clause specifying the Address attribute. Therefore, the special-purpose at_clause syntax is now obsolete.

The above equivalence implies, for example, that only one at_clause is allowed for a given entity. Similarly, it is illegal to give both an at_clause and an attribute_definition_clause specifying the Address attribute.

Extensions to Ada 83

We now allow to define the address of an entity using an attribute_definition_clause. This is because Ada 83's at_clause is so hard to remember: programmers often tend to write "for X'Address use...;".

Wording Changes from Ada 83

Ada 83's address_clause is now called an at_clause to avoid confusion with the new term "Address clause" (that is, an attribute_definition_clause for the Address attribute).

J.7.1 Interrupt Entries

[Implementations are permitted to allow the attachment of task entries to interrupts via the address clause. Such an entry is referred to as an *interrupt entry*.

The address of the task entry corresponds to a hardware interrupt in an implementation-defined manner. (See Ada.Interrupts.Reference in C.3.2.)]

Static Semantics

The following attribute is defined:

4 For any task entry X:

5 X'Address For a task entry whose address is specified (an *interrupt entry*), the value refers to the corresponding hardware interrupt. For such an entry, as for any other task entry, the meaning of this value is implementation defined. The value of this attribute is of the type of the subtype System.Address.

6 Address may be specified for single entries via an attribute_definition_clause.

6.a **Reason:** Because of the equivalence of at_clauses and attribute_definition_clauses, an interrupt entry may be specified via either notation.

Dynamic Semantics

7 As part of the initialization of a task object, the address clause for an interrupt entry is elaborated[, which evaluates the expression of the address clause]. A check is made that the address specified is associated with some interrupt to which a task entry may be attached. If this check fails, Program_Error is raised. Otherwise, the interrupt entry is attached to the interrupt associated with the specified address.

8 Upon finalization of the task object, the interrupt entry, if any, is detached from the corresponding interrupt and the default treatment is restored.

9 While an interrupt entry is attached to an interrupt, the interrupt is reserved (see C.3).

10 An interrupt delivered to a task entry acts as a call to the entry issued by a hardware task whose priority is in the System.Interrupt_Priority range. It is implementation defined whether the call is performed as an ordinary entry call, a timed entry call, or a conditional entry call; which kind of call is performed can depend on the specific interrupt.

Bounded (Run-Time) Errors

11 It is a bounded error to evaluate E'Caller (see C.7.1) in an accept_statement for an interrupt entry. The possible effects are the same as for calling Current_Task from an entry body.

Documentation Requirements

12 The implementation shall document to which interrupts a task entry may be attached.

12.a/2 **Documentation Requirement:** The interrupts to which a task entry may be attached.

13 The implementation shall document whether the invocation of an interrupt entry has the effect of an ordinary entry call, conditional call, or a timed call, and whether the effect varies in the presence of pending interrupts.

13.a/2 **Documentation Requirement:** The type of entry call invoked for an interrupt entry.

Implementation Permissions

14 The support for this subclause is optional.

15 Interrupts to which the implementation allows a task entry to be attached may be designated as reserved for the entire duration of program execution[; that is, not just when they have an interrupt entry attached to them].

16/1 {*8652/0077*} {*AI95-00111-01*} Interrupt entry calls may be implemented by having the hardware execute directly the appropriate accept_statement. Alternatively, the implementation is allowed to provide an internal interrupt handler to simulate the effect of a normal task calling the entry.

17 The implementation is allowed to impose restrictions on the specifications and bodies of tasks that have interrupt entries.

18 It is implementation defined whether direct calls (from the program) to interrupt entries are allowed.

If a select_statement contains both a terminate_alternative and an accept_alternative for an interrupt entry, then an implementation is allowed to impose further requirements for the selection of the terminate_alternative in addition to those given in 9.3. 19

NOTE 1 {*8652/0077*} {*AI95-00111-01*} Queued interrupts correspond to ordinary entry calls. Interrupts that are lost if not immediately processed correspond to conditional entry calls. It is a consequence of the priority rules that an accept_statement executed in response to an interrupt can be executed with the active priority at which the hardware generates the interrupt, taking precedence over lower priority tasks, without a scheduling action. 20/1

NOTE 2 Control information that is supplied upon an interrupt can be passed to an associated interrupt entry as one or more parameters of mode **in**. 21

Examples

Example of an interrupt entry: 22

```
task Interrupt_Handler is                                                    23
  entry Done;
  for Done'Address use Ada.Interrupts.Reference(Ada.Interrupts.Names.Device_Done);
end Interrupt_Handler;
```

Wording Changes from Ada 83

{*AI95-00114-01*} RM83-13.5.1 did not adequately address the problems associated with interrupts. This feature is now obsolescent and is replaced by the Ada 95 interrupt model as specified in the Systems Programming Annex. 23.a/2

Wording Changes from Ada 95

{*8652/0077*} {*AI95-00111-01*} **Corrigendum:** The undefined term *accept body* was replaced by accept_statement. 23.b/2

J.8 Mod Clauses

Syntax

mod_clause ::= **at mod** *static_*expression; 1

Static Semantics

A record_representation_clause of the form: 2

```
{AI05-0092-1} for r use                                                      3/3
    record at mod a;
        ...
    end record;
```

is equivalent to: 4

```
for r'Alignment use a;                                                       5
for r use
    record
        ...
    end record;
```

Reason: The preferred syntax for specifying the alignment of an entity is an attribute_definition_clause specifying the Alignment attribute. Therefore, the special-purpose mod_clause syntax is now obsolete. 5.a

The above equivalence implies, for example, that it is illegal to give both a mod_clause and an attribute_definition_clause specifying the Alignment attribute for the same type. 5.b

Wording Changes from Ada 83

Ada 83's alignment_clause is now called a mod_clause to avoid confusion with the new term “Alignment clause” (that is, an attribute_definition_clause for the Alignment attribute). 5.c

J.9 The Storage_Size Attribute

Static Semantics

1 For any task subtype T, the following attribute is defined:

2 T'Storage_Size

Denotes an implementation-defined value of type *universal_integer* representing the number of storage elements reserved for a task of the subtype T.

2.a/3 **To be honest:** {*AI05-0229-1*} T'Storage_Size cannot be particularly meaningful in the presence of the specification of the aspect Storage_Size, especially when the expression is dynamic, or depends on a discriminant of the task, because the Storage_Size will be different for different objects of the type. Even without such a specification, the Storage_Size can be different for different objects of the type, and in any case, the value is implementation defined. Hence, it is always implementation defined.

3/3 {*AI95-00345-01*} {*AI05-0229-1*} Storage_Size may be specified for a task first subtype that is not an interface via an attribute_definition_clause. When the attribute is specified, the Storage_Size aspect is specified to be the value of the given expression.

3.a/3 **Ramification:** {*AI05-0229-1*} When this attribute is specified with an attribute_definition_clause, the associated aspect is set to the *value* of the expression given in the attribute_definition_clause, rather than the expression itself. This value is therefore the same for all objects of the type; in particular, it is not re-evaluated when objects are created. This is different than when the aspect is specified with an aspect_specification (see 13.3).

Wording Changes from Ada 95

3.b/2 {*AI95-00345-01*} We don't allow specifying Storage_Size on task interfaces. We don't need to mention class-wide task types, because these cannot be a first subtype.

J.10 Specific Suppression of Checks

1/2 {*AI95-00224-01*} Pragma Suppress can be used to suppress checks on specific entities.

Syntax

2/2 {*AI95-00224-01*} The form of a specific Suppress pragma is as follows:

3/2 **pragma** Suppress(identifier, [On =>] name);

Legality Rules

4/2 {*AI95-00224-01*} The identifier shall be the name of a check (see 11.5). The name shall statically denote some entity.

5/2 {*AI95-00224-01*} For a specific Suppress pragma that is immediately within a package_specification, the name shall denote an entity (or several overloaded subprograms) declared immediately within the package_specification.

Static Semantics

6/2 {*AI95-00224-01*} A specific Suppress pragma applies to the named check from the place of the pragma to the end of the innermost enclosing declarative region, or, if the pragma is given in a package_specification, to the end of the scope of the named entity. The pragma applies only to the named entity, or, for a subtype, on objects and values of its type. A specific Suppress pragma suppresses the named check for any entities to which it applies (see 11.5). Which checks are associated with a specific entity is not defined by this document.

6.a/2 **Discussion:** The language doesn't specify exactly which entities control whether a check is performed. For example, in

6.b
```
pragma Suppress (Range_Check, On => A);
A := B;
```

whether or not the range check is performed is not specified. The compiler may require that checks are suppressed on B or on the type of A in order to omit the range check. 6.c

Implementation Permissions

{*AI95-00224-01*} An implementation is allowed to place restrictions on specific Suppress pragmas. 7/2

NOTE {*AI95-00224-01*} {*AI12-0440-1*} An implementation can support a similar On parameter on pragma Unsuppress (see 11.5). 8/5

Wording Changes from Ada 95

{*AI95-00224-01*} {*AI05-0299-1*} This subclause is new. This feature was moved here because it is important for pragma Unsuppress that there be an unambiguous meaning for each checking pragma. For instance, in the example 8.a/3

```
pragma Suppress (Range_Check);
pragma Unsuppress (Range_Check, On => A);
A := B;
```
8.b

the user needs to be able to depend on the range check being made on the assignment. But a compiler survey showed that the interpretation of this feature varied widely; trying to define this carefully was likely to cause a lot of user and implementer pain. Thus the feature was moved here, to emphasize that its use is not portable. 8.c

J.11 The Class Attribute of Untagged Incomplete Types

Static Semantics

{*AI95-00326-01*} For the first subtype S of a type *T* declared by an incomplete_type_declaration that is not tagged, the following attribute is defined: 1/2

{*AI95-00326-01*} S'Class 2/2

Denotes the first subtype of the incomplete class-wide type rooted at *T*. The completion of *T* shall declare a tagged type. Such an attribute reference shall occur in the same library unit as the incomplete_type_declaration.

Reason: {*AI95-00326-01*} This must occur in the same unit to prevent children from imposing requirements on their ancestor library units for deferred incomplete types. 2.a/2

Wording Changes from Ada 95

{*AI95-00326-01*} {*AI05-0299-1*} This subclause is new. This feature was moved here because the tagged incomplete type provides a better way to provide this capability (it doesn't put requirements on the completion based on uses that could be anywhere). Pity we didn't think of it in 1994. 2.b/3

J.12 Pragma Interface

Syntax

{*AI95-00284-02*} In addition to an identifier, the reserved word **interface** is allowed as a pragma name, to provide compatibility with a prior edition of this Reference Manual. 1/2

Implementation Note: {*AI95-00284-02*} All implementations need to at least recognize and ignore this pragma. A syntax error is not an acceptable implementation of this pragma. 1.a/2

Wording Changes from Ada 95

{*AI95-00326-01*} {*AI05-0299-1*} This subclause is new. This is necessary as **interface** is now a reserved word, which would prevent pragma Interface from being an implementation-defined pragma. We don't define any semantics for this pragma, as we expect that implementations will continue to use whatever they currently implement - requiring any changes would be counter-productive. 1.b/3

J.13 Dependence Restriction Identifiers

1/2 {*AI95-00394-01*} The following restrictions involve dependence on specific language-defined units. The more general restriction No_Dependence (see 13.12.1) should be used for this purpose.

Static Semantics

2/2 {*AI95-00394-01*} The following *restriction*_identifiers exist:

3/2 {*AI95-00394-01*} No_Asynchronous_Control
Semantic dependence on the predefined package Asynchronous_Task_Control is not allowed.

4/2 {*AI95-00394-01*} No_Unchecked_Conversion
Semantic dependence on the predefined generic function Unchecked_Conversion is not allowed.

5/2 {*AI95-00394-01*} No_Unchecked_Deallocation
Semantic dependence on the predefined generic procedure Unchecked_Deallocation is not allowed.

Wording Changes from Ada 95

5.a/3 {*AI95-00394-01*} {*AI05-0299-1*} This subclause is new. These restrictions are replaced by the more general No_Dependence (see 13.12.1).

J.14 Character and Wide_Character Conversion Functions

Static Semantics

1/2 {*AI95-00395-01*} The following declarations exist in the declaration of package Ada.Characters.Handling:

2/2
```
function Is_Character (Item : in Wide_Character) return Boolean
   renames Conversions.Is_Character;
function Is_String    (Item : in Wide_String)    return Boolean
   renames Conversions.Is_String;
```

3/2
```
function To_Character (Item       : in Wide_Character;
                       Substitute : in Character := ' ')
                       return Character
   renames Conversions.To_Character;
```

4/2
```
function To_String    (Item       : in Wide_String;
                        Substitute : in Character := ' ')
                        return String
   renames Conversions.To_String;
```

5/2
```
function To_Wide_Character (Item : in Character) return Wide_Character
   renames Conversions.To_Wide_Character;
```

6/2
```
function To_Wide_String    (Item : in String)    return Wide_String
   renames Conversions.To_Wide_String;
```

Wording Changes from Ada 95

6.a/3 {*AI95-00394-01*} {*AI05-0299-1*} This subclause is new. These subprograms were moved to Characters.Conversions (see A.3.4).

J.15 Aspect-related Pragmas

1/3 {*AI05-0229-1*} Pragmas can be used as an alternative to aspect_specifications to specify certain aspects.

Name Resolution Rules

{*AI12-0417-1*} Certain pragmas are defined to be *program unit pragmas*. A name given as the argument of a program unit pragma shall resolve to denote the declarations or renamings of one or more program units that occur immediately within the declarative region or compilation in which the pragma immediately occurs, or it shall resolve to denote the declaration of the immediately enclosing program unit (if any); the pragma applies to the denoted program unit(s). If there are no names given as arguments, the pragma applies to the immediately enclosing program unit. 2/5

Ramification: The fact that this is a Name Resolution Rule means that the pragma will not apply to declarations from outer declarative regions. 2.a/5

Legality Rules

{*AI12-0417-1*} A program unit pragma shall appear in one of these places: 3/5

- {*AI12-0417-1*} At the place of a compilation_unit, in which case the pragma shall immediately follow in the same compilation (except for other pragmas) a library_unit_declaration that is a subprogram_declaration, generic_subprogram_declaration, or generic_instantiation, and the pragma shall have an argument that is a name denoting that declaration. 4/5

  Ramification: The name has to denote the immediately preceding library_unit_declaration. 4.a/5

- {*8652/0033*} {*AI95-00136-01*} {*AI12-0417-1*} Immediately within the visible part of a program unit and before any nested declaration (but not within a generic formal part), in which case the argument, if any, shall be a direct_name that denotes the immediately enclosing program unit declaration. 5/5

  Ramification: The argument is optional in this case. 5.a/5

- {*AI12-0417-1*} At the place of a declaration other than the first, of a declarative_part or program unit declaration, in which case the pragma shall have an argument, which shall be a direct_name that denotes one or more of the following (and nothing else): a subprogram_declaration, a generic_subprogram_declaration, or a generic_instantiation, of the same declarative_part or program unit declaration. 6/5

  Ramification: If you want to denote a subprogram_body that is not a completion, or a package_declaration, for example, you have to put the pragma inside. 6.a/5

{*AI05-0132-1*} {*AI12-0417-1*} Certain program unit pragmas are defined to be *library unit pragmas*. If a library unit pragma applies to a program unit, the program unit shall be a library unit. 7/5

Ramification: This, together with the rules for program unit pragmas above, implies that if a library unit pragma applies to a subprogram_declaration (and similar things), it has to appear immediately after the compilation_unit, whereas if the pragma applies to a package_declaration, a subprogram_body that is not a completion (and similar things), it has to appear inside, as the first declarative_item. 7.a/5

Static Semantics

{*8652/0034*} {*AI95-00041-01*} {*AI12-0417-1*} A library unit pragma that applies to a generic unit does not apply to its instances, unless a specific rule for the pragma specifies the contrary. 8/5

Implementation Advice

{*8652/0034*} {*AI95-00041-01*} {*AI12-0417-1*} When applied to a generic unit, a program unit pragma that is not a library unit pragma should apply to each instance of the generic unit for which there is not an overriding pragma applied directly to the instance. 9/5

Implementation Advice: When applied to a generic unit, a program unit pragma that is not a library unit pragma should apply to each instance of the generic unit for which there is not an overriding pragma applied directly to the instance. 9.a/5

Wording Changes from Ada 2005

9.b/3 {*AI05-0229-1*} {*AI05-0299-1*} This subclause is new. Many existing pragmas have been converted into aspects; the pragmas have moved here.

9.c/5 {*AI05-0132-1*} {*AI12-0417-1*} **Correction:** A library unit pragma must apply directly to a library unit, even if no name is given in the pragma.

Wording Changes from Ada 2012

9.d/5 {*AI12-0417-1*} The terms “program unit pragma” and “library unit pragma” were moved here as all of the pragmas that use these terms are now in this annex.

J.15.1 Pragma Inline

Syntax

1/3 {*AI05-0229-1*} The form of a pragma Inline, which is a program unit pragma (see 10.1.5), is as follows:

2/3 **pragma** Inline (name{, name});

Legality Rules

3/3 {*AI05-0229-1*} The pragma shall apply to one or more callable entities or generic subprograms.

Static Semantics

4/3 {*AI05-0229-1*} Pragma Inline specifies that the Inline aspect (see 6.3.2) for each entity denoted by each name given in the pragma has the value True.

4.a/3 **Ramification:** Note that inline expansion is desired no matter what name is used in the call. This allows one to request inlining for only one of several overloaded subprograms as follows:

4.b/3
```
package IO is
   procedure Put(X : in Integer);
   procedure Put(X : in String);
   procedure Put(X : in Character);
private
   procedure Character_Put(X : in Character) renames Put;
   pragma Inline(Character_Put);
end IO;
```

4.c/3
```
with IO; use IO;
procedure Main is
   I : Integer;
   C : Character;
begin
   ...
   Put(C); -- Inline expansion is desired.
   Put(I); -- Inline expansion is NOT desired.
end Main;
```

Implementation Permissions

5/3 {*AI05-0229-1*} An implementation may allow a pragma Inline that has an argument which is a direct_name denoting a subprogram_body of the same declarative_part.

5.a/3 **Reason:** This is allowed for Ada 83 compatibility. This is only a permission as this usage was considered obsolescent even for Ada 95.

5.b/3 **Discussion:** We only need to allow this in declarative_parts, because a body is only allowed in another body, and these all have declarative_parts.

6/5 NOTE {*AI05-0229-1*} {*AI12-0440-1*} The name in a pragma Inline can denote more than one entity in the case of overloading. Such a pragma applies to all of the denoted entities.

Incompatibilities With Ada 83

{*AI95-00309-01*} {*AI05-0229-1*} A pragma Inline cannot refer to a subprogram_body outside of that body. The pragma can be given inside of the subprogram body. Ada 2005 adds an Implementation Permission to allow this usage for compatibility (and Ada 95 implementations also can use this permission), but implementations do not have to allow such pragmas. 6.a/3

Extensions to Ada 83

{*AI05-0229-1*} A pragma Inline is allowed inside a subprogram_body if there is no corresponding subprogram_declaration. This is for uniformity with other program unit pragmas. 6.b/3

Extensions to Ada 95

{*AI95-00309-01*} {*AI05-0229-1*} **Amendment Correction:** Implementations are allowed to let Pragma Inline apply to a subprogram_body. 6.c/3

Wording Changes from Ada 2005

{*AI05-0229-1*} {*AI05-0299-1*} This subclause is new. Pragma Inline was moved here from 6.3.2; aspect Inline lives there now. 6.d/3

J.15.2 Pragma No_Return

Syntax

{*AI05-0229-1*} The form of a pragma No_Return, which is a representation pragma (see 13.1), is as follows: 1/3

{*AI12-0269-1*} **pragma** No_Return (*subprogram*_local_name{, *subprogram*_local_name}); 2/5

Legality Rules

{*AI05-0229-1*} {*AI12-0269-1*} Each *subprogram*_local_name shall denote one or more subprograms or generic subprograms. [The *subprogram*_local_name shall not denote a null procedure nor an instance of a generic unit.] 3/5

Static Semantics

{*AI05-0229-1*} {*AI12-0269-1*} Pragma No_Return specifies that the No_Return aspect (see 6.5.1) for each subprogram denoted by each local_name given in the pragma has the value True. 4/5

Wording Changes from Ada 2005

{*AI05-0229-1*} {*AI05-0299-1*} This subclause is new. Pragma No_Return was moved here from 6.5.1; aspect No_Return lives there now. 4.a/3

Wording Changes from Ada 2012

{*AI12-0269-1*} This subclause is new. Pragma No_Return was moved here from 6.5.1; aspect No_Return lives there now. 4.b/5

J.15.3 Pragma Pack

Syntax

{*AI05-0229-1*} The form of a pragma Pack, which is a representation pragma (see 13.1), is as follows: 1/3

pragma Pack (*first_subtype*_local_name); 2/3

Legality Rules

3/3 {*AI05-0229-1*} The *first_subtype*_local_name of a pragma Pack shall denote a composite subtype.

Static Semantics

4/3 {*AI05-0229-1*} Pragma Pack specifies that the Pack aspect (see 13.2) for the type denoted by *first_subtype*_local_name has the value True.

Wording Changes from Ada 2005

4.a/3 {*AI05-0229-1*} {*AI05-0299-1*} This subclause is new. Pragma Pack was moved here from 13.2; aspect Pack lives there now.

J.15.4 Pragma Storage_Size

Syntax

1/3 {*AI05-0229-1*} The form of a pragma Storage_Size is as follows:

2/3 **pragma** Storage_Size (expression);

3/3 {*AI05-0229-1*} A pragma Storage_Size is allowed only immediately within a task_definition.

Name Resolution Rules

4/3 {*AI05-0229-1*} The expression of a pragma Storage_Size is expected to be of any integer type.

Static Semantics

5/3 {*AI05-0229-1*} The pragma Storage_Size sets the Storage_Size aspect (see 13.3) of the type defined by the immediately enclosing task_definition to the value of the expression of the pragma.

Wording Changes from Ada 2005

5.a/3 {*AI05-0229-1*} {*AI05-0299-1*} This subclause is new. Pragma Storage_Size was moved here from 13.3; aspect Storage_Size lives there now.

J.15.5 Interfacing Pragmas

Syntax

1/3 {*AI05-0229-1*} An *interfacing pragma* is a representation pragma that is one of the pragmas Import, Export, or Convention. Their forms are as follows:

2/3 **pragma** Import(
[Convention =>] *convention*_identifier, [Entity =>] local_name
[, [External_Name =>] *external_name_string*_expression]
[, [Link_Name =>] *link_name_string*_expression]);

3/3 **pragma** Export(
[Convention =>] *convention*_identifier, [Entity =>] local_name
[, [External_Name =>] *external_name_string*_expression]
[, [Link_Name =>] *link_name_string*_expression]);

4/3 **pragma** Convention([Convention =>] *convention*_identifier,[Entity =>] local_name);

5/3 {*AI05-0229-1*} For pragmas Import and Export, the argument for Link_Name shall not be given without the *pragma_argument*_identifier unless the argument for External_Name is given.

Name Resolution Rules

{*AI05-0229-1*} The expected type for an *external_name_string*_expression and a *link_name_string*_expression in an interfacing pragma is String. 6/3

Legality Rules

{*AI05-0229-1*} The *convention*_identifier of an interfacing pragma shall be the name of a convention (see B.1). 7/3

{*AI05-0229-1*} A pragma Import shall be the completion of a declaration. Notwithstanding any rule to the contrary, a pragma Import may serve as the completion of any kind of (explicit) declaration if supported by an implementation for that kind of declaration. If a completion is a pragma Import, then it shall appear in the same declarative_part, package_specification, task_definition, or protected_definition as the declaration. For a library unit, it shall appear in the same compilation, before any subsequent compilation_units other than pragmas. If the local_name denotes more than one entity, then the pragma Import is the completion of all of them. 8/3

{*AI05-0229-1*} The *external_name_string*_expression and *link_name_string*_expression of a pragma Import or Export shall be static. 9/3

{*AI05-0229-1*} The local_name of each of these pragmas shall denote a declaration that may have the similarly named aspect specified. 10/3

Static Semantics

{*AI05-0229-1*} An interfacing pragma specifies various aspects of the entity denoted by the local_name as follows: 11/3

- The Convention aspect (see B.1) is *convention*_identifier. 12/3
- A pragma Import specifies that the Import aspect (see B.1) is True. 13/3
- A pragma Export specifies that the Export aspect (see B.1) is True. 14/3
- For both pragma Import and Export, if an external name is given in the pragma, the External_Name aspect (see B.1) is specified to be *external_name_string*_expression. If a link name is given in the pragma, the Link_Name aspect (see B.1) is specified to be the *link_name_string*_expression. 15/3

Wording Changes from Ada 2005

{*AI05-0229-1*} {*AI05-0299-1*} This subclause is new. Pragmas Import, Export, and Convention were moved here from B.1; aspects Import, Export, Convention, Link_Name, and External_Name live there now. 15.a/3

J.15.6 Pragma Unchecked_Union

Syntax

{*AI05-0229-1*} The form of a pragma Unchecked_Union, which is a representation pragma (see 13.1), is as follows: 1/3

pragma Unchecked_Union (*first_subtype*_local_name); 2/3

Legality Rules

{*AI05-0229-1*} The *first_subtype*_local_name of a pragma Unchecked_Union shall denote an unconstrained discriminated record subtype having a variant_part. 3/3

Static Semantics

4/3 {*AI05-0229-1*} A pragma Unchecked_Union specifies that the Unchecked_Union aspect (see B.3.3) for the type denoted by *first_subtype*_local_name has the value True.

Wording Changes from Ada 2005

4.a/3 {*AI05-0229-1*} {*AI05-0299-1*} This subclause is new. Pragma Unchecked_Union was moved here from B.3.3; aspect Unchecked_Union lives there now.

J.15.7 Pragmas Interrupt_Handler and Attach_Handler

Syntax

1/3 {*AI05-0229-1*} The form of a pragma Interrupt_Handler is as follows:

2/3 **pragma** Interrupt_Handler (*handler*_name);

3/3 {*AI05-0229-1*} The form of a pragma Attach_Handler is as follows:

4/3 **pragma** Attach_Handler (*handler*_name, expression);

Name Resolution Rules

5/3 {*AI05-0229-1*} For the Interrupt_Handler and Attach_Handler pragmas, the *handler*_name shall resolve to denote a protected procedure with a parameterless profile.

6/3 {*AI05-0229-1*} For the Attach_Handler pragma, the expected type for the expression is Interrupts.Interrupt_Id (see C.3.2).

Legality Rules

7/3 {*AI05-0033-1*} {*AI05-0229-1*} The Attach_Handler and Interrupt_Handler pragmas are only allowed immediately within the protected_definition where the corresponding subprogram is declared. The corresponding protected_type_declaration or single_protected_declaration shall be a library-level declaration, and shall not be declared within a generic body. In addition to the places where Legality Rules normally apply (see 12.3), these rules also apply in the private part of an instance of a generic unit.

7.a/3 **Discussion:** In the case of a protected_type_declaration, an object_declaration of an object of that type need not be at library level.

7.b/3 {*AI05-0033-1*} We cannot allow these pragmas in a generic body, because legality rules are not checked for instance bodies, and these should not be allowed if the instance is not at the library level. The protected types can be declared in the private part if this is desired. Note that while the 'Access to use the handler would provide the check in the case of Interrupt_Handler, there is no other check for Attach_Handler. Since these pragmas are so similar, we want the rules to be the same.

Static Semantics

8/3 {*AI05-0229-1*} For an implementation that supports Annex C, a pragma Interrupt_Handler specifies the Interrupt_Handler aspect (see C.3.1) for the protected procedure *handler*_name to have the value True. For an implementation that supports Annex C, a pragma Attach_Handler specifies the Attach_Handler aspect (see C.3.1) for the protected procedure *handler*_name to have the value of the given expression[as evaluated at object creation time].

Incompatibilities With Ada 2005

8.a/3 {*AI05-0033-1*} **Correction:** Added missing generic contract wording for the pragma Attach_Handler and Interrupt_Handler. This means that nested instances with these pragmas in the private part are now illegal. This is not likely to occur in practice.

Wording Changes from Ada 2005

{*AI05-0229-1*} {*AI05-0299-1*} This subclause is new. Pragmas Interrupt_Handler and Attach_Handler were moved here from C.3.1; aspects Interrupt_Handler and Attach_Handler live there now. 8.b/3

J.15.8 Shared Variable Pragmas

Syntax

{*AI05-0229-1*} {*AI12-0425-1*} The following pragmas are defined with the given forms: 1/5

pragma Atomic (local_name); 2/3

pragma Volatile (local_name); 3/3

{*AI05-0009-1*} **pragma** Independent (*component*_local_name); 4/3

pragma Atomic_Components (*array*_local_name); 5/3

pragma Volatile_Components (*array*_local_name); 6/3

{*AI05-0009-1*} **pragma** Independent_Components (local_name); 7/3

Discussion: {*AI05-0009-1*} {*AI05-0229-1*} Pragmas Independent and Independent_Components are born obsolescent; they are defined to provide consistency with the existing shared variable pragmas. As with all obsolescent features, these pragmas are not optional; all Ada implementations need to implement them. Also note that these pragmas were defined as a **Correction**; as such, they are expected to be implemented as part of Ada 2005 implementations (and they would not be obsolescent there). 7.a/3

Name Resolution Rules

{*AI05-0009-1*} {*AI05-0229-1*} The local_name in an Atomic or Volatile pragma shall resolve to denote either an object_declaration, a noninherited component_declaration, or a full_type_declaration. The *component*_local_name in an Independent pragma shall resolve to denote a noninherited component_declaration. The *array*_local_name in an Atomic_Components or Volatile_Components pragma shall resolve to denote the declaration of an array type or an array object of an anonymous type. The local_name in an Independent_Components pragma shall resolve to denote the declaration of an array or record type or an array object of an anonymous type. 8/3

Static Semantics

{*AI05-0229-1*} These pragmas are representation pragmas (see 13.1). Each of these pragmas specifies that the similarly named aspect (see C.6) of the type, object, or component denoted by its argument is True. 9/3

Legality Rules

{*AI05-0229-1*} The local_name of each of these pragmas shall denote a declaration that may have the similarly named aspect specified. 10/3

Wording Changes from Ada 2005

{*AI05-0229-1*} {*AI05-0299-1*} This subclause is new. These pragmas were moved here from C.6; various aspects live there now. 10.a/3

J.15.9 Pragma CPU

Discussion: {*AI05-0229-1*} This pragma is born obsolescent; it is defined to provide consistency with existing real-time pragmas. As with all obsolescent features, this pragma is not optional; all Ada implementations need to implement it. 0.a/3

Syntax

1/3 {*AI05-0229-1*} The form of a pragma CPU is as follows:

2/3 **pragma** CPU (expression);

Name Resolution Rules

3/3 {*AI05-0229-1*} The expected type for the expression of a pragma CPU is System.Multiprocessors.CPU_Range.

Legality Rules

4/5 {*AI05-0229-1*} {*AI12-0281-1*} A CPU pragma is allowed only immediately within a task_definition, protected_definition, or the declarative_part of a subprogram_body.

5/3 {*AI05-0229-1*} For a CPU pragma that appears in the declarative_part of a subprogram_body, the expression shall be static.

Static Semantics

6/5 {*AI05-0229-1*} {*AI12-0281-1*} For an implementation that supports Annex D, a pragma CPU specifies the value of the CPU aspect (see D.16). If the pragma appears in a task_definition, the expression is associated with the aspect for the task type or single_task_declaration that contains the pragma. If the pragma appears in a protected_definition, the expression is associated with the aspect for the protected type or single_protected_declaration that contains the pragma. Otherwise, the expression is associated with the aspect for the subprogram that contains the pragma.

Extensions to Ada 2005

6.a/3 {*AI05-0009-1*} Pragma CPU is new.

J.15.10 Pragma Dispatching_Domain

0.a/3 **Discussion:** {*AI05-0167-1*} This pragma is born obsolescent; it is defined to provide consistency with existing real-time pragmas. As with all obsolescent features, this pragma is not optional; all Ada implementations need to implement it.

Syntax

1/3 {*AI05-0167-1*} The form of a pragma Dispatching_Domain is as follows:

2/3 **pragma** Dispatching_Domain (expression);

Name Resolution Rules

3/3 {*AI05-0167-1*} The expected type for the expression is System.Multiprocessors.Dispatching_Domains.-Dispatching_Domain.

Legality Rules

4/3 {*AI05-0167-1*} A Dispatching_Domain pragma is allowed only immediately within a task_definition.

Static Semantics

5/3 {*AI05-0167-1*} For an implementation that supports Annex D, a pragma Dispatching_Domain specifies the value of the Dispatching_Domain aspect (see D.16.1). The expression is associated with the aspect for the task type or single_task_declaration that contains the pragma.

Extensions to Ada 2005

{*AI05-0009-1*} Pragma Dispatching_Domain is new. 5.a/3

J.15.11 Pragmas Priority and Interrupt_Priority

Syntax

{*AI05-0229-1*} The form of a pragma Priority is as follows: 1/3

pragma Priority (expression); 2/3

{*AI05-0229-1*} The form of a pragma Interrupt_Priority is as follows: 3/3

pragma Interrupt_Priority [(expression);] 4/3

Name Resolution Rules

{*AI05-0229-1*} The expected type for the expression in a Priority or Interrupt_Priority pragma is Integer. 5/3

Legality Rules

{*AI05-0229-1*} A Priority pragma is allowed only immediately within a task_definition, a protected_definition, or the declarative_part of a subprogram_body. An Interrupt_Priority pragma is allowed only immediately within a task_definition or a protected_definition. 6/3

{*AI05-0229-1*} For a Priority pragma that appears in the declarative_part of a subprogram_body, the expression shall be static, and its value shall be in the range of System.Priority. 7/3

Static Semantics

{*AI05-0229-1*} For an implementation that supports Annex D, a pragma Priority specifies the value of the Priority aspect (see D.1) and a pragma Interrupt_Priority specifies the value of the Interrupt_Priority aspect as follows: 8/3

- If the pragma appears in a task_definition, the expression is associated with the aspect for the task type or single_task_declaration that contains the pragma; 9/3
- If the pragma appears in a protected_definition, the expression is associated with the aspect for the protected type or single_protected_declaration that contains the pragma; 10/3
- If the pragma appears in the declarative_part of a subprogram_body, the expression is associated with the aspect for the subprogram that contains the pragma. 11/3

{*AI05-0229-1*} If there is no expression in an Interrupt_Priority pragma, the Interrupt_Priority aspect has the value Interrupt_Priority'Last. 12/3

Wording Changes from Ada 2005

{*AI05-0229-1*} {*AI05-0299-1*} This subclause is new. Pragmas Interrupt_Priority and Priority were moved here from D.1; aspects Interrupt_Priority and Priority live there now. 12.a/3

J.15.12 Pragma Relative_Deadline

Syntax

{*AI05-0229-1*} The form of a pragma Relative_Deadline is as follows: 1/3

pragma Relative_Deadline (*relative_deadline*_expression); 2/3

Name Resolution Rules

3/3 {*AI05-0229-1*} The expected type for a *relative_deadline*_expression is Real_Time.Time_Span.

Legality Rules

4/3 {*AI05-0229-1*} A Relative_Deadline pragma is allowed only immediately within a task_definition or the declarative_part of a subprogram_body.

Static Semantics

5/3 {*AI05-0229-1*} For an implementation that supports Annex D, a pragma Relative_Deadline specifies the value of the Relative_Deadline aspect (see D.2.6). If the pragma appears in a task_definition, the expression is associated with the aspect for the task type or single_task_declaration that contains the pragma; otherwise, the expression is associated with the aspect for the subprogram that contains the pragma.

Wording Changes from Ada 2005

5.a/3 {*AI05-0229-1*} {*AI05-0299-1*} This subclause is new. Pragma Relative_Deadline was moved here from D.2.6; aspect Relative_Deadline lives there now.

J.15.13 Pragma Asynchronous

Syntax

1/3 {*AI05-0229-1*} The form of a pragma Asynchronous, which is a representation pragma (see 13.1), is as follows:

2/3 **pragma** Asynchronous (local_name);

Static Semantics

3/3 {*AI05-0229-1*} For an implementation that supports Annex E, a pragma Asynchronous specifies that the Asynchronous aspect (see E.4.1) for the procedure or type denoted by local_name has the value True.

Legality Rules

4/3 {*AI05-0229-1*} The local_name of a pragma Asynchronous shall denote a declaration that may have aspect Asynchronous specified.

Wording Changes from Ada 2005

4.a/3 {*AI05-0229-1*} {*AI05-0299-1*} This subclause is new. Pragma Asynchronous was moved here from E.4.1; aspect Asynchronous lives there now.

J.15.14 Elaboration Control Pragmas

1/5 {*AI12-0409-1*} This subclause defines pragmas that specify aspects that help control the elaboration order of library_items.

1.a/5 **Discussion:** {*AI12-0417-1*} Pragmas that do not have associated aspects still appear in 10.2.1. These pragmas are presented in the order that the aspects are defined in 10.2.1.

Syntax

2/5 {*AI12-0417-1*} The following pragmas are defined with the given forms:

3/5 **pragma** Preelaborate[(*library_unit*_name)];

4/5 **pragma** Preelaborable_Initialization(direct_name);

pragma Pure[(*library_unit*_name)]; 5/5

pragma Elaborate_Body[(*library_unit*_name)]; 6/5

{*AI12-0417-1*} Pragmas Preelaborate, Pure, and Elaborate_Body are library unit pragmas. 7/5

Ramification: Pragma Preelaborable_Initialization is **not** a library unit pragma. 7.a/5

Static Semantics

{*AI12-0417-1*} A pragma Preelaborate specifies that a library unit is preelaborated, namely that the Preelaborate aspect (see 10.2.1) of the library unit is True. 8/5

{*AI12-0417-1*} A pragma Pure specifies that a library unit is declared pure, namely that the Pure aspect (see 10.2.1) of the library unit is True. 9/5

{*AI12-0417-1*} A pragma Elaborate_Body specifies that [a library unit requires a completion, namely that] the Elaborate_Body aspect (see 10.2.1) of the library unit is True. 10/5

Legality Rules

{*AI12-0409-1*} A pragma Preelaborable_Initialization specifies that the Preelaborable_Initialization aspect (see 10.2.1) for a composite type is True. This pragma shall appear in the visible part of a package or generic package. 11/5

{*AI12-0409-1*} If the pragma appears in the first declaration list of a package_specification, then the direct_name shall denote the first subtype of a composite type, and the type shall be declared immediately within the same package as the pragma. The composite type shall be one for which the Preelaborable_Initialization aspect can be directly specified as True. In addition to the places where Legality Rules normally apply (see 12.3), these rules also apply in the private part of an instance of a generic unit. 12/5

{*AI12-0409-1*} If the pragma appears in a generic_formal_part, then the direct_name shall denote a type declared in the same generic_formal_part as the pragma, and be one for which the Preelaborable_Initialization aspect can be directly specified as True. 13/5

NOTE {*AI12-0409-1*} Pragmas Elaborate and Elaborate_All, which do not have associated aspects, are found in 10.2.1. 14/5

Wording Changes from Ada 2012

{*AI12-0409-1*} This subclause is new. These pragmas were moved here from 10.2.1. 14.a/5

J.15.15 Distribution Pragmas

{*AI12-0417-1*} This subclause defines pragmas that specify properties of units for distributed systems. 1/5

Discussion: {*AI12-0417-1*} These pragmas are presented in the order that the aspects are defined in Annex E. 1.a/5

Syntax

{*AI12-0417-1*} The following pragmas are defined with the given forms: 2/5

pragma Shared_Passive[(*library_unit*_name)]; 3/5

pragma Remote_Types[(*library_unit*_name)]; 4/5

pragma Remote_Call_Interface[(*library_unit*_name)]; 5/5

pragma All_Calls_Remote[(*library_unit*_name)]; 6/5

{*AI12-0417-1*} Each of these pragmas is a library unit pragma. 7/5

Static Semantics

8/5 {*AI12-0417-1*} A *categorization pragma* is a pragma that specifies a corresponding categorization aspect.

9/5 {*AI12-0417-1*} The pragmas Shared_Passive, Remote_Types, and Remote_Call_Interface are categorization pragmas. In addition, the pragma Pure (see J.15.14) is considered a categorization pragma.

10/5 {*AI12-0417-1*} A pragma Shared_Passive specifies that a library unit is a shared passive library unit, namely that the Shared_Passive aspect (see E.2.1) of the library unit is True.

11/5 {*AI12-0417-1*} A pragma Remote_Types specifies that a library unit is a remote types library unit, namely that the Remote_Types aspect (see E.2.2) of the library unit is True.

12 A pragma Remote_Call_Interface specifies that a library unit is a remote call interface, namely that the Remote_Call_Interface aspect (see E.2.3) of the library unit is True.

13 A pragma All_Calls_Remote specifies that the All_Calls_Remote aspect (see E.2.3) of the library unit is True.

Wording Changes from Ada 2012

13.a/5 {*AI12-0417-1*} This subclause is new. These pragmas were moved here from Annex E, “Distributed Systems”.

Annex K
(informative)
Language-Defined Aspects and Attributes

{*AI05-0229-1*} This annex summarizes the definitions given elsewhere of the language-defined aspects and attributes. Some aspects have corresponding attributes, as noted. 1/3

K.1 Language-Defined Aspects

{*AI05-0229-1*} {*AI05-0299-1*} This subclause summarizes the definitions given elsewhere of the language-defined aspects. Aspects are properties of entities that can be specified by the Ada program; unless otherwise specified below, aspects can be specified using an aspect_specification. 1/3

Address Machine address of an entity. See 13.3. 2/3

Aggregate Mechanism to define user-defined aggregates. See 4.3.5. 2.1/5

Alignment (object) 3/3
Alignment of an object. See 13.3.

Alignment (subtype) 4/3
Alignment of a subtype. See 13.3.

All_Calls_Remote 5/4
All indirect or dispatching remote subprogram calls, and all direct remote subprogram calls, should use the Partition Communication Subsystem. See E.2.3.

Allows_Exit 5.1/5
An indication of whether a subprogram will operate correctly for arbitrary transfers of control. See 5.5.3.

Asynchronous 6/3
Remote procedure calls are asynchronous; the caller continues without waiting for the call to return. See E.4.1.

Atomic Declare that a type, object, or component is atomic. See C.6. 7/3

Atomic_Components 8/3
Declare that the components of an array type or object are atomic. See C.6.

Attach_Handler 9/3
Protected procedure is attached to an interrupt. See C.3.1.

Bit_Order Order of bit numbering in a record_representation_clause. See 13.5.3. 10/3

Coding Internal representation of enumeration literals. Specified by an enumeration_representation_clause, not by an aspect_specification. See 13.4. 11/3

Component_Size 12/3
Size in bits of a component of an array type. See 13.3.

Constant_Indexing 13/3
Defines function(s) to implement user-defined indexed_components. See 4.1.6.

Convention Calling convention or other convention used for interfacing to other languages. See B.1. 14/3

CPU Processor on which a given task, or calling task for a protected operation, should run. See D.16. 15/5

16/3 Default_Component_Value
Default value for the components of an array-of-scalar subtype. See 3.6.

16.1/5 Default_Initial_Condition
A condition that will hold true after the default initialization of an object. See 7.3.3.

17/3 Default_Iterator
Default iterator to be used in **for** loops. See 5.5.1.

18/3 Default_Storage_Pool
Default storage pool for a generic instance. See 13.11.3.

19/3 Default_Value
Default value for a scalar subtype. See 3.5.

19.1/4 Discard_Names
Requests a reduction in storage for names associated with an entity. See C.5.

19.2/5 Dispatching
Generic formal parameters used in the implementation of an entity. See H.7.1.

20/3 Dispatching_Domain
Domain (group of processors) on which a given task should run. See D.16.1.

21/5 Dynamic_Predicate
Condition that will hold true for objects of a given subtype; the subtype is not static. See 3.2.4.

22/5 Elaborate_Body
A given package will have a body, and that body is elaborated immediately after the declaration. See 10.2.1.

22.1/4 Exclusive_Functions
Specifies mutual exclusion behavior of protected functions in a protected type. See 9.5.1.

23/3 Export Entity is exported to another language. See B.1.

24/3 External_Name
Name used to identify an imported or exported entity. See B.1.

25/3 External_Tag
Unique identifier for a tagged type in streams. See 13.3.

25.1/5 Full_Access_Only
Declare that a volatile type, object, or component is full access. See C.6.

25.2/5 Global Global object usage contract. See 6.1.2.

25.3/5 Global'Class
Global object usage contract inherited on derivation. See 6.1.2.

26/3 Implicit_Dereference
Mechanism for user-defined implicit .**all**. See 4.1.5.

27/3 Import Entity is imported from another language. See B.1.

28/3 Independent Declare that a type, object, or component is independently addressable. See C.6.

29/3 Independent_Components
Declare that the components of an array or record type, or an array object, are independently addressable. See C.6.

30/3 Inline For efficiency, Inline calls are requested for a subprogram. See 6.3.2.

Input — Function to read a value from a stream for a given type, including any bounds and discriminants. See 13.13.2. 31/3

Input'Class — 31.1/4
Function to read a value from a stream for a the class-wide type associated with a given type, including any bounds and discriminants. See 13.13.2.

Integer_Literal — 31.2/5
Defines a function to implement user-defined integer literals. See 4.2.1.

Interrupt_Handler — 32/3
Protected procedure may be attached to interrupts. See C.3.1.

Interrupt_Priority — 33/3
Priority of a task object or type, or priority of a protected object or type; the priority is in the interrupt range. See D.1.

Iterator_Element — 34/3
Element type to be used for user-defined iterators. See 5.5.1.

Iterator_View — 34.1/5
An alternative type to used for container element iterators. See 5.5.1.

Layout (record) — 35/3
Layout of record components. Specified by a record_representation_clause, not by an aspect_specification. See 13.5.1.

Link_Name Linker symbol used to identify an imported or exported entity. See B.1. 36/3

Machine_Radix — 37/3
Radix (2 or 10) that is used to represent a decimal fixed point type. See F.1.

Max_Entry_Queue_Length — 37.1/5
The maximum entry queue length for a task type, protected type, or entry. See D.4.

No_Controlled_Parts — 37.2/5
A specification that a type and its descendants do not have controlled parts. See H.4.1.

No_Return A subprogram will not return normally. See 6.5.1. 38/5

Nonblocking — 38.1/5
Specifies that an associated subprogram does not block. See 9.5.

Output — Procedure to write a value to a stream for a given type, including any bounds and discriminants. See 13.13.2. 39/3

Output'Class — 39.1/4
Procedure to write a value to a stream for a the class-wide type associated with a given type, including any bounds and discriminants. See 13.13.2.

Pack — Minimize storage when laying out records and arrays. See 13.2. 40/3

Parallel_Calls — 40.1/5
Specifies whether a given subprogram is expected to be called in parallel. See 9.10.1.

Parallel_Iterator — 40.2/5
An indication of whether a subprogram may use multiple threads of control to invoke a loop body procedure. See 5.5.3.

Post — Postcondition; a condition that will hold true after a call. See 6.1.1. 41/5

Post'Class — Postcondition that applies to corresponding subprograms of descendant types. See 6.1.1. 42/5

Pre — Precondition; a condition that is expected to hold true before a call. See 6.1.1. 43/5

44/5 Pre'Class Precondition that applies to corresponding subprograms of descendant types. See 6.1.1.

44.1/4 Predicate_Failure
Action to be performed when a predicate check fails. See 3.2.4.

44.2/5 Preelaborable_Initialization
Declares that a type has preelaborable initialization. See 10.2.1.

45/3 Preelaborate
Code execution during elaboration is avoided for a given package. See 10.2.1.

46/3 Priority Priority of a task object or type, or priority of a protected object or type; the priority is not in the interrupt range. See D.1.

47/3 Pure Side effects are avoided in the subprograms of a given package. See 10.2.1.

47.1/5 Put_Image Procedure to define the image of a given type. See 4.10.

48/3 Read Procedure to read a value from a stream for a given type. See 13.13.2.

48.1/4 Read'Class Procedure to read a value from a stream for the class-wide type associated with a given type. See 13.13.2.

48.2/5 Real_Literal
Defines a function or functions to implement user-defined real literals. See 4.2.1.

49/3 Record layout
See Layout. See 13.5.1.

50/5 Relative_Deadline
Task or protected type parameter used in Earliest Deadline First Dispatching. See D.2.6.

51/3 Remote_Call_Interface
Subprograms in a given package may be used in remote procedure calls. See E.2.3.

52/3 Remote_Types
Types in a given package may be used in remote procedure calls. See E.2.2.

53/3 Shared_Passive
A given package is used to represent shared memory in a distributed system. See E.2.1.

54/3 Size (object)
Size in bits of an object. See 13.3.

55/3 Size (subtype)
Size in bits of a subtype. See 13.3.

56/3 Small Scale factor for a fixed point type. See 3.5.10.

56.1/5 Stable_Properties
A list of functions describing characteristics that usually are unchanged by primitive operations of the type or an individual primitive subprogram. See 7.3.4.

56.2/5 Stable_Properties'Class
A list of functions describing characteristics that usually are unchanged by primitive operations of a class of types or a primitive subprogram for such a class. See 7.3.4.

56.3/5 Static Specifies that an associated expression function can be used in static expressions. See 6.8.

57/5 Static_Predicate
Condition that will hold true for objects of a given subtype; the subtype may be static. See 3.2.4.

58/3 Storage_Pool
Pool of memory from which **new** will allocate for a given access type. See 13.11.

Storage_Size (access) 59/3
Sets memory size for allocations for an access type. See 13.11.

Storage_Size (task) 60/3
Size in storage elements reserved for a task type or single task object. See 13.3.

Stream_Size 61/3
Size in bits used to represent elementary objects in a stream. See 13.13.2.

String_Literal 61.1/5
Defines a function to implement user-defined string literals. See 4.2.1.

Synchronization 62/5
Defines whether a given primitive operation of a synchronized interface will be implemented by an entry or protected procedure. See 9.5.

Type_Invariant 63/3
A condition that will hold true for all objects of a type. See 7.3.2.

Type_Invariant'Class 64/3
A condition that will hold true for all objects in a class of types. See 7.3.2.

Unchecked_Union 65/3
Type is used to interface to a C union type. See B.3.3.

Use_Formal 65.1/5
Generic formal parameters used in the implementation of an entity. See H.7.1.

Variable_Indexing 66/3
Defines function(s) to implement user-defined indexed_components. See 4.1.6.

Volatile Declare that a type, object, or component is volatile. See C.6. 67/3

Volatile_Components 68/3
Declare that the components of an array type or object are volatile. See C.6.

Write Procedure to write a value to a stream for a given type. See 13.13.2. 69/3

Write'Class 69.1/4
Procedure to write a value to a stream for a the class-wide type associated with a given type. See 13.13.2.

Yield Ensures that a callable entity includes a task dispatching point. See D.2.1. 69.2/5

K.2 Language-Defined Attributes

{*AI05-0229-1*} {*AI05-0299-1*} This subclause summarizes the definitions given elsewhere of the language-defined attributes. Attributes are properties of entities that can be queried by an Ada program. 1/3

P'Access For a prefix P that denotes a subprogram: 2

P'Access yields an access value that designates the subprogram denoted by P. The type of P'Access is an access-to-subprogram type (*S*), as determined by the expected type. See 3.10.2. 3

X'Access For a prefix X that denotes an aliased view of an object: 4

X'Access yields an access value that designates the object denoted by X. The type of X'Access is an access-to-object type, as determined by the expected type. The expected type shall be a general access type. See 3.10.2. 5

X'Address For a prefix X that denotes an object, program unit, or label: 6/1

7 Denotes the address of the first of the storage elements allocated to X. For a program unit or label, this value refers to the machine code associated with the corresponding body or statement. The value of this attribute is of type System.Address. See 13.3.

8 S'Adjacent For every subtype S of a floating point type *T*:

9 S'Adjacent denotes a function with the following specification:

10
```
function S'Adjacent (X, Towards : T)
  return T
```

11 If *Towards* = *X*, the function yields *X*; otherwise, it yields the machine number of the type *T* adjacent to *X* in the direction of *Towards*, if that machine number exists. If the result would be outside the base range of S, Constraint_Error is raised. When *T*'Signed_Zeros is True, a zero result has the sign of *X*. When *Towards* is zero, its sign has no bearing on the result. See A.5.3.

12 S'Aft For every fixed point subtype S:

13 S'Aft yields the number of decimal digits needed after the decimal point to accommodate the *delta* of the subtype S, unless the *delta* of the subtype S is greater than 0.1, in which case the attribute yields the value one. (S'Aft is the smallest positive integer N for which (10**N)*S'Delta is greater than or equal to one.) The value of this attribute is of the type *universal_integer*. See 3.5.10.

13.1/2 S'Alignment

For every subtype S:

13.2/2 The value of this attribute is of type *universal_integer*, and nonnegative.

13.3/2 For an object X of subtype S, if S'Alignment is not zero, then X'Alignment is a nonzero integral multiple of S'Alignment unless specified otherwise by a representation item. See 13.3.

14/1 X'Alignment

For a prefix X that denotes an object:

15/2 The value of this attribute is of type *universal_integer*, and nonnegative; zero means that the object is not necessarily aligned on a storage element boundary. If X'Alignment is not zero, then X is aligned on a storage unit boundary and X'Address is an integral multiple of X'Alignment (that is, the Address modulo the Alignment is zero).

16/2 See 13.3.

17 S'Base For every scalar subtype S:

18 S'Base denotes an unconstrained subtype of the type of S. This unconstrained subtype is called the *base subtype* of the type. See 3.5.

19 S'Bit_Order

For every specific record subtype S:

20 Denotes the bit ordering for the type of S. The value of this attribute is of type System.Bit_Order. See 13.5.3.

21/1 P'Body_Version

For a prefix P that statically denotes a program unit:

22 Yields a value of the predefined type String that identifies the version of the compilation unit that contains the body (but not any subunits) of the program unit. See E.3.

23 T'Callable For a prefix T that is of a task type (after any implicit dereference):

24 Yields the value True when the task denoted by T is *callable*, and False otherwise; See 9.9.

E'Caller For a prefix E that denotes an entry_declaration: 25

Yields a value of the type Task_Id that identifies the task whose call is now being serviced. Use of this attribute is allowed only inside an accept_statement, or entry_body after the entry_barrier, corresponding to the entry_declaration denoted by E. See C.7.1. 26/3

S'Ceiling For every subtype S of a floating point type *T*: 27

S'Ceiling denotes a function with the following specification: 28

```
function S'Ceiling (X : T)
  return T
```
29

The function yields the value $\lceil X \rceil$, that is, the smallest (most negative) integral value greater than or equal to *X*. When *X* is zero, the result has the sign of *X*; a zero result otherwise has a negative sign when S'Signed_Zeros is True. See A.5.3. 30/5

S'Class For every subtype S of a tagged type *T* (specific or class-wide): 31

S'Class denotes a subtype of the class-wide type (called *T*'Class in this document) for the class rooted at *T* (or if S already denotes a class-wide subtype, then S'Class is the same as S). 32

S'Class is unconstrained. However, if S is constrained, then the values of S'Class are only those that when converted to the type *T* belong to S. See 3.9. 33

S'Class For every subtype S of an untagged private type whose full view is tagged: 34

Denotes the class-wide subtype corresponding to the full view of S. This attribute is allowed only from the beginning of the private part in which the full view is declared, until the declaration of the full view. After the full view, the Class attribute of the full view can be used. See 7.3.1. 35

X'Component_Size 36/1

For a prefix X that denotes an array subtype or array object (after any implicit dereference):

Denotes the size in bits of components of the type of X. The value of this attribute is of type *universal_integer*. See 13.3. 37

S'Compose For every subtype S of a floating point type *T*: 38

S'Compose denotes a function with the following specification: 39

```
function S'Compose (Fraction : T;
                    Exponent : universal_integer)
  return T
```
40

Let *v* be the value $Fraction \cdot T\text{'Machine\_Radix}^{Exponent-k}$, where *k* is the normalized exponent of *Fraction*. If *v* is a machine number of the type *T*, or if $|v| \geq T\text{'Model\_Small}$, the function yields *v*; otherwise, it yields either one of the machine numbers of the type *T* adjacent to *v*. Constraint_Error is optionally raised if *v* is outside the base range of S. A zero result has the sign of *Fraction* when S'Signed_Zeros is True. See A.5.3. 41

A'Constrained 42

For a prefix A that is of a discriminated type (after any implicit dereference):

Yields the value True if A denotes a constant, a value, a tagged object, or a constrained variable, and False otherwise. The value of this attribute is of the predefined type Boolean. See 3.7.2. 43/5

S'Copy_Sign 44

For every subtype S of a floating point type *T*:

S'Copy_Sign denotes a function with the following specification: 45

```
function S'Copy_Sign (Value, Sign : T)
  return T
```
46

47 If the value of *Value* is nonzero, the function yields a result whose magnitude is that of *Value* and whose sign is that of *Sign*; otherwise, it yields the value zero. Constraint_Error is optionally raised if the result is outside the base range of S. A zero result has the sign of *Sign* when S'Signed_Zeros is True. See A.5.3.

48 E'Count For a prefix E that denotes an entry of a task or protected unit:

49 Yields the number of calls presently queued on the entry E of the current instance of the unit. The value of this attribute is of the type *universal_integer*. See 9.9.

50/1 S'Definite For a prefix S that denotes a formal indefinite subtype:

51/3 S'Definite yields True if the actual subtype corresponding to S is definite; otherwise, it yields False. The value of this attribute is of the predefined type Boolean. See 12.5.1.

52 S'Delta For every fixed point subtype S:

53 S'Delta denotes the *delta* of the fixed point subtype S. The value of this attribute is of the type *universal_real*. See 3.5.10.

54 S'Denorm For every subtype S of a floating point type *T*:

55 Yields the value True if every value expressible in the form

$$\pm\, mantissa \cdot T\text{'Machine\_Radix}^{T\text{'Machine\_Emin}}$$

where *mantissa* is a nonzero *T*'Machine_Mantissa-digit fraction in the number base *T*'Machine_Radix, the first digit of which is zero, is a machine number (see 3.5.7) of the type *T*; yields the value False otherwise. The value of this attribute is of the predefined type Boolean. See A.5.3.

56 S'Digits For every floating point subtype S:

57 S'Digits denotes the requested decimal precision for the subtype S. The value of this attribute is of the type *universal_integer*. See 3.5.8.

58 S'Digits For every decimal fixed point subtype S:

59 S'Digits denotes the *digits* of the decimal fixed point subtype S, which corresponds to the number of decimal digits that are representable in objects of the subtype. The value of this attribute is of the type *universal_integer*. See 3.5.10.

59.1/5 S'Enum_Rep

For every discrete subtype S:

59.2/5 S'Enum_Rep denotes a function with the following specification:

59.3/5
```
function S'Enum_Rep (Arg : S'Base) return universal_integer
```

59.4/5 This function returns the representation value of the value of Arg, as a value of type *universal_integer*. The *representation value* is the internal code specified in an enumeration representation clause, if any, for the type corresponding to the value of Arg, and otherwise is the position number of the value. See 13.4.

59.5/5 S'Enum_Val

For every discrete subtype S:

59.6/5 S'Enum_Val denotes a function with the following specification:

59.7/5
```
function S'Enum_Val (Arg : universal_integer) return S'Base
```

59.8/5 This function returns a value of the type of S whose representation value equals the value of Arg. For the evaluation of a call on S'Enum_Val, if there is no value in the base range of its type with the given representation value, Constraint_Error is raised. See 13.4.

60 S'Exponent For every subtype S of a floating point type *T*:

61 S'Exponent denotes a function with the following specification:

```
function S'Exponent (X : T)
  return universal_integer
```

62

The function yields the normalized exponent of *X*. See A.5.3. 63

S'External_Tag 64

For every subtype S of a tagged type *T* (specific or class-wide):

S'External_Tag denotes an external string representation for S'Tag; it is of the predefined type String. External_Tag may be specified for a specific tagged type via an attribute_definition_clause; the expression of such a clause shall be static. The default external tag representation is implementation defined. See 13.13.2. See 13.3. 65

A'First For a prefix A that is of an array type (after any implicit dereference), or denotes a constrained array subtype: 66/1

A'First denotes the lower bound of the first index range; its type is the corresponding index type. See 3.6.2. 67

S'First For every scalar subtype S: 68

S'First denotes the lower bound of the range of S. The value of this attribute is of the type of S. See 3.5. 69

A'First(N) 70/1

For a prefix A that is of an array type (after any implicit dereference), or denotes a constrained array subtype:

A'First(N) denotes the lower bound of the N-th index range; its type is the corresponding index type. See 3.6.2. 71

R.C'First_Bit 72

For a component C of a composite, non-array object R:

If the nondefault bit ordering applies to the composite type, and if a component_clause specifies the placement of C, denotes the value given for the first_bit of the component_clause; otherwise, denotes the offset, from the start of the first of the storage elements occupied by C, of the first bit occupied by C. This offset is measured in bits. The first bit of a storage element is numbered zero. The value of this attribute is of the type *universal_integer*. See 13.5.2. 73/2

S'First_Valid 73.1/4

For every static discrete subtype S for which there exists at least one value belonging to S that satisfies the predicates of S:

S'First_Valid denotes the smallest value that belongs to S and satisfies the predicates of S. The value of this attribute is of the type of S. See 3.5.5. 73.2/4

S'Floor For every subtype S of a floating point type *T*: 74

S'Floor denotes a function with the following specification: 75

```
function S'Floor (X : T)
  return T
```

76

The function yields the value $\lfloor X \rfloor$, that is, the largest (most positive) integral value less than or equal to *X*. When *X* is zero, the result has the sign of *X*; a zero result otherwise has a positive sign. See A.5.3. 77/5

S'Fore For every fixed point subtype S: 78

S'Fore yields the minimum number of characters needed before the decimal point for the decimal representation of any value of the subtype S, assuming that the representation does not include an exponent, but includes a one-character prefix that is either a minus sign or a 79

space. (This minimum number does not include superfluous zeros or underlines, and is at least 2.) The value of this attribute is of the type *universal_integer*. See 3.5.10.

80 S'Fraction For every subtype S of a floating point type *T*:

81 S'Fraction denotes a function with the following specification:

82
```
function S'Fraction (X : T)
  return T
```

83 The function yields the value $X \cdot T\text{'Machine\_Radix}^{-k}$, where *k* is the normalized exponent of *X*. A zero result, which can only occur when *X* is zero, has the sign of *X*. See A.5.3.

83.1/3 X'Has_Same_Storage
For a prefix X that denotes an object:

83.2/4 X'Has_Same_Storage denotes a function with the following specification:

83.3/3
```
function X'Has_Same_Storage (Arg : any_type)
  return Boolean
```

83.4/4 The actual parameter shall be a name that denotes an object. The object denoted by the actual parameter can be of any type. This function evaluates the names of the objects involved. It returns True if the representation of the object denoted by the actual parameter occupies exactly the same bits as the representation of the object denoted by X and the objects occupy at least one bit; otherwise, it returns False. See 13.3.

84/1 E'Identity For a prefix E that denotes an exception:

85 E'Identity returns the unique identity of the exception. The type of this attribute is Exception_Id. See 11.4.1.

86 T'Identity For a prefix T that is of a task type (after any implicit dereference):

87 Yields a value of the type Task_Id that identifies the task denoted by T. See C.7.1.

88 S'Image For every subtype S of a type T:

89/5 S'Image denotes a function with the following specification:

90/5
```
function S'Image(Arg : S'Base)
  return String
```

91/5 S'Image calls S'Put_Image passing *Arg* (which will typically store a sequence of character values in a text buffer) and then returns the result of retrieving the contents of that buffer with function Get. See 4.10.

91.1/5 X'Image For a prefix X of a type T other than *universal_real* or *universal_fixed*:

91.2/5 X'Image denotes the result of calling function S'Image with *Arg* being X, where S is the nominal subtype of X. See 4.10.

91.3/5 E'Index For a prefix E that denotes an entry declaration of an entry family:

91.4/5 Within a precondition or postcondition expression for entry family E, denotes the value of the entry index for the call of E. The nominal subtype of this attribute is the entry index subtype. See 6.1.1.

92 S'Class'Input
For every subtype S'Class of a class-wide type *T*'Class:

93 S'Class'Input denotes a function with the following specification:

94/2
```
function S'Class'Input(
   Stream : not null access Ada.Streams.Root_Stream_Type'Class)
   return T'Class
```

95/5 First reads the external tag from *Stream* and determines the corresponding internal tag (by calling Tags.Descendant_Tag(String'Input(*Stream*), S'Tag) which can raise Tag_Error — see

3.9) and then dispatches to the subprogram denoted by the Input attribute of the specific type identified by the internal tag; returns that result. If the specific type identified by the internal tag is abstract, Constraint_Error is raised. See 13.13.2.

S'Input For every subtype S of a specific type *T*: 96

S'Input denotes a function with the following specification: 97

```
function S'Input(
   Stream : not null access Ada.Streams.Root_Stream_Type'Class)
   return T
```
98/2

S'Input reads and returns one value from *Stream*, using any bounds or discriminants written by a corresponding S'Output to determine how much to read. See 13.13.2. 99

A'Last For a prefix A that is of an array type (after any implicit dereference), or denotes a constrained array subtype: 100/1

A'Last denotes the upper bound of the first index range; its type is the corresponding index type. See 3.6.2. 101

S'Last For every scalar subtype S: 102

S'Last denotes the upper bound of the range of S. The value of this attribute is of the type of S. See 3.5. 103

A'Last(N) For a prefix A that is of an array type (after any implicit dereference), or denotes a constrained array subtype: 104/1

A'Last(N) denotes the upper bound of the N-th index range; its type is the corresponding index type. See 3.6.2. 105

R.C'Last_Bit 106

For a component C of a composite, non-array object R:

If the nondefault bit ordering applies to the composite type, and if a component_clause specifies the placement of C, denotes the value given for the last_bit of the component_clause; otherwise, denotes the offset, from the start of the first of the storage elements occupied by C, of the last bit occupied by C. This offset is measured in bits. The value of this attribute is of the type *universal_integer*. See 13.5.2. 107/2

S'Last_Valid 107.1/4

For every static discrete subtype S for which there exists at least one value belonging to S that satisfies the predicates of S:

S'Last_Valid denotes the largest value that belongs to S and satisfies the predicates of S. The value of this attribute is of the type of S. See 3.5.5. 107.2/4

S'Leading_Part 108

For every subtype S of a floating point type *T*:

S'Leading_Part denotes a function with the following specification: 109

```
function S'Leading_Part (X : T;
                         Radix_Digits : universal_integer)
  return T
```
110

Let *v* be the value *T*'Machine_Radix$^{k-Radix_Digits}$, where *k* is the normalized exponent of *X*. The function yields the value 111

- $\lfloor X/v \rfloor \cdot v$, when *X* is nonnegative and *Radix_Digits* is positive; 112
- $\lceil X/v \rceil \cdot v$, when *X* is negative and *Radix_Digits* is positive. 113

Constraint_Error is raised when *Radix_Digits* is zero or negative. A zero result, which can only occur when *X* is zero, has the sign of *X*. See A.5.3. 114

115/1 A'Length For a prefix A that is of an array type (after any implicit dereference), or denotes a constrained array subtype:

116 A'Length denotes the number of values of the first index range (zero for a null range); its type is *universal_integer*. See 3.6.2.

117/1 A'Length(N)
For a prefix A that is of an array type (after any implicit dereference), or denotes a constrained array subtype:

118 A'Length(N) denotes the number of values of the N-th index range (zero for a null range); its type is *universal_integer*. See 3.6.2.

119 S'Machine For every subtype S of a floating point type *T*:

120 S'Machine denotes a function with the following specification:

121
```
function S'Machine (X : T)
  return T
```

122 If *X* is a machine number of the type *T*, the function yields *X*; otherwise, it yields the value obtained by rounding or truncating *X* to either one of the adjacent machine numbers of the type *T*. Constraint_Error is raised if rounding or truncating *X* to the precision of the machine numbers results in a value outside the base range of S. A zero result has the sign of *X* when S'Signed_Zeros is True. See A.5.3.

123 S'Machine_Emax
For every subtype S of a floating point type *T*:

124 Yields the largest (most positive) value of *exponent* such that every value expressible in the canonical form (for the type *T*), having a *mantissa* of *T*'Machine_Mantissa digits, is a machine number (see 3.5.7) of the type *T*. This attribute yields a value of the type *universal_integer*. See A.5.3.

125 S'Machine_Emin
For every subtype S of a floating point type *T*:

126 Yields the smallest (most negative) value of *exponent* such that every value expressible in the canonical form (for the type *T*), having a *mantissa* of *T*'Machine_Mantissa digits, is a machine number (see 3.5.7) of the type *T*. This attribute yields a value of the type *universal_integer*. See A.5.3.

127 S'Machine_Mantissa
For every subtype S of a floating point type *T*:

128 Yields the largest value of *p* such that every value expressible in the canonical form (for the type *T*), having a *p*-digit *mantissa* and an *exponent* between *T*'Machine_Emin and *T*'Machine_Emax, is a machine number (see 3.5.7) of the type *T*. This attribute yields a value of the type *universal_integer*. See A.5.3.

129 S'Machine_Overflows
For every subtype S of a floating point type *T*:

130 Yields the value True if overflow and divide-by-zero are detected and reported by raising Constraint_Error for every predefined operation that yields a result of the type *T*; yields the value False otherwise. The value of this attribute is of the predefined type Boolean. See A.5.3.

131 S'Machine_Overflows
For every subtype S of a fixed point type *T*:

132 Yields the value True if overflow and divide-by-zero are detected and reported by raising Constraint_Error for every predefined operation that yields a result of the type *T*; yields the

value False otherwise. The value of this attribute is of the predefined type Boolean. See A.5.4.

S'Machine_Radix 133

For every subtype S of a floating point type *T*:

Yields the radix of the hardware representation of the type *T*. The value of this attribute is of the type *universal_integer*. See A.5.3. 134

S'Machine_Radix 135

For every subtype S of a fixed point type *T*:

Yields the radix of the hardware representation of the type *T*. The value of this attribute is of the type *universal_integer*. See A.5.4. 136

S'Machine_Rounding 136.1/2

For every subtype S of a floating point type *T*:

S'Machine_Rounding denotes a function with the following specification: 136.2/2

```
function S'Machine_Rounding (X : T)                    136.3/2
  return T
```

The function yields the integral value nearest to *X*. If *X* lies exactly halfway between two integers, one of those integers is returned, but which of them is returned is unspecified. A zero result has the sign of *X* when S'Signed_Zeros is True. This function provides access to the rounding behavior which is most efficient on the target processor. See A.5.3. 136.4/2

S'Machine_Rounds 137

For every subtype S of a floating point type *T*:

Yields the value True if rounding is performed on inexact results of every predefined operation that yields a result of the type *T*; yields the value False otherwise. The value of this attribute is of the predefined type Boolean. See A.5.3. 138

S'Machine_Rounds 139

For every subtype S of a fixed point type *T*:

Yields the value True if rounding is performed on inexact results of every predefined operation that yields a result of the type *T*; yields the value False otherwise. The value of this attribute is of the predefined type Boolean. See A.5.4. 140

S'Max For every scalar subtype S: 141

S'Max denotes a function with the following specification: 142

```
function S'Max(Left, Right : S'Base)                   143
  return S'Base
```

The function returns the greater of the values of the two parameters. See 3.5. 144

S'Max_Alignment_For_Allocation 144.1/3

For every subtype S:

Denotes the maximum value for Alignment that can be requested by the implementation via Allocate for an access type whose designated subtype is S. The value of this attribute is of type *universal_integer*. See 13.11.1. 144.2/5

S'Max_Size_In_Storage_Elements 145

For every subtype S:

Denotes the maximum value for Size_In_Storage_Elements that can be requested by the implementation via Allocate for an access type whose designated subtype is S. The value of this attribute is of type *universal_integer*. See 13.11.1. 146/5

S'Min For every scalar subtype S: 147

148 S'Min denotes a function with the following specification:

149
```
function S'Min(Left, Right : S'Base)
  return S'Base
```

150 The function returns the lesser of the values of the two parameters. See 3.5.

150.1/2 S'Mod For every modular subtype S:

150.2/2 S'Mod denotes a function with the following specification:

150.3/2
```
function S'Mod (Arg : universal_integer)
  return S'Base
```

150.4/2 This function returns *Arg* **mod** S'Modulus, as a value of the type of S. See 3.5.4.

151 S'Model For every subtype S of a floating point type *T*:

152 S'Model denotes a function with the following specification:

153
```
function S'Model (X : T)
  return T
```

154 If the Numerics Annex is not supported, the meaning of this attribute is implementation defined; see G.2.2 for the definition that applies to implementations supporting the Numerics Annex. See A.5.3.

155 S'Model_Emin
For every subtype S of a floating point type *T*:

156 If the Numerics Annex is not supported, this attribute yields an implementation defined value that is greater than or equal to the value of *T*'Machine_Emin. See G.2.2 for further requirements that apply to implementations supporting the Numerics Annex. The value of this attribute is of the type *universal_integer*. See A.5.3.

157 S'Model_Epsilon
For every subtype S of a floating point type *T*:

158 Yields the value $T\text{'Machine\_Radix}^{1 - T\text{'Model\_Mantissa}}$. The value of this attribute is of the type *universal_real*. See A.5.3.

159 S'Model_Mantissa
For every subtype S of a floating point type *T*:

160 If the Numerics Annex is not supported, this attribute yields an implementation defined value that is greater than or equal to $\lceil d \cdot \log(10) / \log(T\text{'Machine\_Radix}) \rceil + 1$, where d is the requested decimal precision of *T*, and less than or equal to the value of *T*'Machine_Mantissa. See G.2.2 for further requirements that apply to implementations supporting the Numerics Annex. The value of this attribute is of the type *universal_integer*. See A.5.3.

161 S'Model_Small
For every subtype S of a floating point type *T*:

162 Yields the value $T\text{'Machine\_Radix}^{T\text{'Model\_Emin} - 1}$. The value of this attribute is of the type *universal_real*. See A.5.3.

163 S'Modulus For every modular subtype S:

164 S'Modulus yields the modulus of the type of S, as a value of the type *universal_integer*. See 3.5.4.

164.1/5 S'Object_Size
For every subtype S:

164.2/5 If S is definite, denotes the size (in bits) of a stand-alone aliased object, or a component of subtype S in the absence of an aspect_specification or representation item that specifies the

size of the object or component. If S is indefinite, the meaning is implementation-defined. The value of this attribute is of the type *universal_integer*. See 13.3.

X'Old

For a prefix X that denotes an object of a nonlimited type: 164.3/3

Each X'Old in a postcondition expression that is enabled, other than those that occur in subexpressions that are determined to be unevaluated, denotes a constant that is implicitly declared at the beginning of the subprogram body, entry body, or accept statement. See 6.1.1. 164.4/5

S'Class'Output 165

For every subtype S'Class of a class-wide type *T*'Class:

S'Class'Output denotes a procedure with the following specification: 166

```
procedure S'Class'Output(                                                    167/2
   Stream : not null access Ada.Streams.Root_Stream_Type'Class;
   Item   : in T'Class)
```

First writes the external tag of *Item* to *Stream* (by calling String'Output(*Stream*, Tags.External_Tag(*Item*'Tag)) — see 3.9) and then dispatches to the subprogram denoted by the Output attribute of the specific type identified by the tag. Tag_Error is raised if the tag of Item identifies a type declared at an accessibility level deeper than that of S. See 13.13.2. 168/2

S'Output

For every subtype S of a specific type *T*: 169

S'Output denotes a procedure with the following specification: 170

```
procedure S'Output(                                                          171/2
   Stream : not null access Ada.Streams.Root_Stream_Type'Class;
   Item : in T)
```

S'Output writes the value of *Item* to *Stream*, including any bounds or discriminants. See 13.13.2. 172

X'Overlaps_Storage 172.1/3

For a prefix X that denotes an object:

X'Overlaps_Storage denotes a function with the following specification: 172.2/3

```
function X'Overlaps_Storage (Arg : any_type)                                 172.3/3
  return Boolean
```

The actual parameter shall be a name that denotes an object. The object denoted by the actual parameter can be of any type. This function evaluates the names of the objects involved and returns True if the representation of the object denoted by the actual parameter shares at least one bit with the representation of the object denoted by X; otherwise, it returns False. See 13.3. 172.4/3

X'Parallel_Reduce(Reducer, Initial_Value) 172.5/5

For a prefix X of an array type (after any implicit dereference), or that denotes an iterable container object (see 5.5.1):

X'Parallel_Reduce is a reduction expression that yields a result equivalent to replacing the attribute identifier with Reduce and the prefix of the attribute with the value_sequence: 172.6/5

```
[parallel for Item of X => Item]                                             172.7/5
```

See 4.5.10. 172.8/5

D'Partition_Id 173/1

For a prefix D that denotes a library-level declaration, excepting a declaration of or within a declared-pure library unit:

Denotes a value of the type *universal_integer* that identifies the partition in which D was elaborated. If D denotes the declaration of a remote call interface library unit (see E.2.3) the given partition is the one where the body of D was elaborated. See E.1. 174

175 S'Pos For every discrete subtype S:

176 S'Pos denotes a function with the following specification:

177
```
function S'Pos(Arg : S'Base)
  return universal_integer
```

178 This function returns the position number of the value of *Arg*, as a value of type *universal_integer*. See 3.5.5.

179 R.C'Position
For a component C of a composite, non-array object R:

180/2 If the nondefault bit ordering applies to the composite type, and if a component_clause specifies the placement of C, denotes the value given for the position of the component_clause; otherwise, denotes the same value as R.C'Address – R'Address. The value of this attribute is of the type *universal_integer*. See 13.5.2.

181 S'Pred For every scalar subtype S:

182 S'Pred denotes a function with the following specification:

183
```
function S'Pred(Arg : S'Base)
  return S'Base
```

184 For an enumeration type, the function returns the value whose position number is one less than that of the value of *Arg*; Constraint_Error is raised if there is no such value of the type. For an integer type, the function returns the result of subtracting one from the value of *Arg*. For a fixed point type, the function returns the result of subtracting *small* from the value of *Arg*. For a floating point type, the function returns the machine number (as defined in 3.5.7) immediately below the value of *Arg*; Constraint_Error is raised if there is no such machine number. See 3.5.

184.1/5 S'Preelaborable_Initialization
For a nonformal composite subtype S declared within the visible part of a package or a generic package, or a generic formal private subtype or formal derived subtype:

184.2/5 This attribute is of Boolean type, and its value reflects whether the type of S has preelaborable initialization. See 10.2.1.

184.3/2 P'Priority For a prefix P that denotes a protected object:

184.4/2 Denotes a non-aliased component of the protected object P. This component is of type System.Any_Priority and its value is the priority of P. P'Priority denotes a variable if and only if P denotes a variable. A reference to this attribute shall appear only within the body of P. See D.5.2.

184.5/5 S'Put_Image
For every subtype S of a type T other than *universal_real* or *universal_fixed*:

184.6/5 S'Put_Image denotes a procedure with the following specification:

184.7/5
```
procedure S'Put_Image
   (Buffer : in out
             Ada.Strings.Text_Buffers.Root_Buffer_Type'Class;
    Arg    : in T);
```

184.8/5 The default implementation of S'Put_Image writes (using Wide_Wide_Put) an *image* of the value of *Arg*. See 4.10.

185/1 A'Range For a prefix A that is of an array type (after any implicit dereference), or denotes a constrained array subtype:

186 A'Range is equivalent to the range A'First .. A'Last, except that the prefix A is only evaluated once. See 3.6.2.

187 S'Range For every scalar subtype S:

S'Range is equivalent to the range S'First .. S'Last. See 3.5. 188

A'Range(N) 189/1

For a prefix A that is of an array type (after any implicit dereference), or denotes a constrained array subtype:

A'Range(N) is equivalent to the range A'First(N) .. A'Last(N), except that the prefix A is only evaluated once. See 3.6.2. 190

S'Class'Read 191

For every subtype S'Class of a class-wide type *T*'Class:

S'Class'Read denotes a procedure with the following specification: 192

```
procedure S'Class'Read(
   Stream : not null access Ada.Streams.Root_Stream_Type'Class;
   Item : out T'Class)
```
193/2

Dispatches to the subprogram denoted by the Read attribute of the specific type identified by the tag of Item. See 13.13.2. 194

S'Read For every subtype S of a specific type *T*: 195

S'Read denotes a procedure with the following specification: 196

```
procedure S'Read(
   Stream : not null access Ada.Streams.Root_Stream_Type'Class;
   Item : out T)
```
197/2

S'Read reads the value of *Item* from *Stream*. See 13.13.2. 198

V'Reduce(Reducer, Initial_Value) 198.1/5

For a value_sequence V:

This attribute represents a *reduction expression*, and is in the form of a reduction_attribute_reference. See 4.5.10. 198.2/5

X'Reduce(Reducer, Initial_Value) 198.3/5

For a prefix X of an array type (after any implicit dereference), or that denotes an iterable container object (see 5.5.1):

X'Reduce is a reduction expression that yields a result equivalent to replacing the prefix of the attribute with the value_sequence: 198.4/5

```
[for Item of X => Item]
```
198.5/5

See 4.5.10. 198.6/5

P'Relative_Deadline 198.7/5

For a prefix P that denotes a protected object:

Denotes a non-aliased component of the protected object P. This component is of type Ada.Real_Time.Time_Span and its value is the relative deadline of P. P'Relative_Deadline denotes a variable if and only if P denotes a variable. A reference to this attribute shall appear only within the body of P. See D.5.2. 198.8/5

S'Remainder 199

For every subtype S of a floating point type *T*:

S'Remainder denotes a function with the following specification: 200

```
function S'Remainder (X, Y : T)
  return T
```
201

For nonzero *Y*, let *v* be the value $X - n \cdot Y$, where *n* is the integer nearest to the exact value of X/Y; if $|n - X/Y| = 1/2$, then *n* is chosen to be even. If *v* is a machine number of the type *T*, the function yields *v*; otherwise, it yields zero. Constraint_Error is raised if *Y* is zero. A zero result has the sign of *X* when S'Signed_Zeros is True. See A.5.3. 202

202.1/3 F'Result For a prefix F that denotes a function declaration or an access-to-function type:

202.2/5 Within a postcondition expression for F, denotes the return object of the function call for which the postcondition expression is evaluated. The type of this attribute is that of the result subtype of the function or access-to-function type except within a Post'Class postcondition expression for a function with a controlling result or with a controlling access result; in those cases the type of the attribute is described above as part of the Name Resolution Rules for Post'Class. See 6.1.1.

203 S'Round For every decimal fixed point subtype S:

204 S'Round denotes a function with the following specification:

205
```
function S'Round(X : universal_real)
  return S'Base
```

206 The function returns the value obtained by rounding X (away from 0, if X is midway between two values of the type of S). See 3.5.10.

207 S'Rounding For every subtype S of a floating point type *T*:

208 S'Rounding denotes a function with the following specification:

209
```
function S'Rounding (X : T)
  return T
```

210 The function yields the integral value nearest to *X*, rounding away from zero if *X* lies exactly halfway between two integers. A zero result has the sign of *X* when S'Signed_Zeros is True. See A.5.3.

211 S'Safe_First
For every subtype S of a floating point type *T*:

212 Yields the lower bound of the safe range (see 3.5.7) of the type *T*. If the Numerics Annex is not supported, the value of this attribute is implementation defined; see G.2.2 for the definition that applies to implementations supporting the Numerics Annex. The value of this attribute is of the type *universal_real*. See A.5.3.

213 S'Safe_Last
For every subtype S of a floating point type *T*:

214 Yields the upper bound of the safe range (see 3.5.7) of the type *T*. If the Numerics Annex is not supported, the value of this attribute is implementation defined; see G.2.2 for the definition that applies to implementations supporting the Numerics Annex. The value of this attribute is of the type *universal_real*. See A.5.3.

215 S'Scale For every decimal fixed point subtype S:

216 S'Scale denotes the *scale* of the subtype S, defined as the value N such that S'Delta = 10.0**(–N). The scale indicates the position of the point relative to the rightmost significant digits of values of subtype S. The value of this attribute is of the type *universal_integer*. See 3.5.10.

217 S'Scaling For every subtype S of a floating point type *T*:

218 S'Scaling denotes a function with the following specification:

219
```
function S'Scaling (X : T;
                    Adjustment : universal_integer)
  return T
```

220 Let *v* be the value $X \cdot T'\text{Machine\_Radix}^{Adjustment}$. If *v* is a machine number of the type *T*, or if $|v| \geq T'\text{Model\_Small}$, the function yields *v*; otherwise, it yields either one of the machine numbers of the type *T* adjacent to *v*. Constraint_Error is optionally raised if *v* is outside the base range of S. A zero result has the sign of *X* when S'Signed_Zeros is True. See A.5.3.

S'Signed_Zeros 221

For every subtype S of a floating point type *T*:

Yields the value True if the hardware representation for the type *T* has the capability of representing both positively and negatively signed zeros, these being generated and used by the predefined operations of the type *T* as specified in IEC 559:1989; yields the value False otherwise. The value of this attribute is of the predefined type Boolean. See A.5.3. 222

S'Size For every subtype S: 223

If S is definite, denotes the size (in bits) that the implementation would choose for the following objects of subtype S: 224

- A record component of subtype S when the record type is packed. 225
- The formal parameter of an instance of Unchecked_Conversion that converts from subtype S to some other subtype. 226

If S is indefinite, the meaning is implementation defined. The value of this attribute is of the type *universal_integer*. See 13.3. 227

X'Size For a prefix X that denotes an object: 228/1

Denotes the size in bits of the representation of the object. The value of this attribute is of the type *universal_integer*. See 13.3. 229

S'Small For every fixed point subtype S: 230

S'Small denotes the *small* of the type of S. The value of this attribute is of the type *universal_real*. See 3.5.10. 231

S'Storage_Pool 232

For every access-to-object subtype S:

Denotes the storage pool of the type of S. The type of this attribute is Root_Storage_-Pool'Class. See 13.11. 233

S'Storage_Size 234

For every access-to-object subtype S:

Yields the result of calling Storage_Size(S'Storage_Pool), which is intended to be a measure of the number of storage elements reserved for the pool. The type of this attribute is *universal_integer*. See 13.11. 235

T'Storage_Size 236/1

For a prefix T that denotes a task object (after any implicit dereference):

Denotes the number of storage elements reserved for the task. The value of this attribute is of the type *universal_integer*. The Storage_Size includes the size of the task's stack, if any. The language does not specify whether or not it includes other storage associated with the task (such as the “task control block” used by some implementations.) See 13.3. 237

S'Stream_Size 237.1/2

For every subtype S of an elementary type *T*:

Denotes the number of bits read from or written to a stream by the default implementations of S'Read and S'Write. Hence, the number of stream elements required per item of elementary type *T* is: 237.2/3

```
T'Stream_Size / Ada.Streams.Stream_Element'Size
```
237.3/2

The value of this attribute is of type *universal_integer* and is a multiple of Stream_Element'Size. See 13.13.2. 237.4/2

S'Succ For every scalar subtype S: 238

239 S'Succ denotes a function with the following specification:

240
```
function S'Succ(Arg : S'Base)
  return S'Base
```

241 For an enumeration type, the function returns the value whose position number is one more than that of the value of *Arg*; Constraint_Error is raised if there is no such value of the type. For an integer type, the function returns the result of adding one to the value of *Arg*. For a fixed point type, the function returns the result of adding *small* to the value of *Arg*. For a floating point type, the function returns the machine number (as defined in 3.5.7) immediately above the value of *Arg*; Constraint_Error is raised if there is no such machine number. See 3.5.

242 S'Tag For every subtype S of a tagged type *T* (specific or class-wide):

243 S'Tag denotes the tag of the type *T* (or if *T* is class-wide, the tag of the root type of the corresponding class). The value of this attribute is of type Tag. See 3.9.

244 X'Tag For a prefix X that is of a class-wide tagged type (after any implicit dereference):

245 X'Tag denotes the tag of X. The value of this attribute is of type Tag. See 3.9.

246 T'Terminated
For a prefix T that is of a task type (after any implicit dereference):

247 Yields the value True if the task denoted by T is terminated, and False otherwise. The value of this attribute is of the predefined type Boolean. See 9.9.

248 S'Truncation
For every subtype S of a floating point type *T*:

249 S'Truncation denotes a function with the following specification:

250
```
function S'Truncation (X : T)
  return T
```

251 The function yields the value $\lceil X \rceil$ when *X* is negative, and $\lfloor X \rfloor$ otherwise. A zero result has the sign of *X* when S'Signed_Zeros is True. See A.5.3.

252 S'Unbiased_Rounding
For every subtype S of a floating point type *T*:

253 S'Unbiased_Rounding denotes a function with the following specification:

254
```
function S'Unbiased_Rounding (X : T)
  return T
```

255 The function yields the integral value nearest to *X*, rounding toward the even integer if *X* lies exactly halfway between two integers. A zero result has the sign of *X* when S'Signed_Zeros is True. See A.5.3.

256 X'Unchecked_Access
For a prefix X that denotes an aliased view of an object:

257 All rules and semantics that apply to X'Access (see 3.10.2) apply also to X'Unchecked_Access, except that, for the purposes of accessibility rules and checks, it is as if X were declared immediately within a library package. See 13.10.

258 S'Val For every discrete subtype S:

259 S'Val denotes a function with the following specification:

260
```
function S'Val(Arg : universal_integer)
  return S'Base
```

261 This function returns a value of the type of S whose position number equals the value of *Arg*. See 3.5.5.

X'Valid For a prefix X that denotes a scalar object (after any implicit dereference): 262

Yields True if and only if the object denoted by X is normal, has a valid representation, and then, if the preceding conditions hold, the value of X also satisfies the predicates of the nominal subtype of X. The value of this attribute is of the predefined type Boolean. See 13.9.2. 263/4

S'Value For every scalar subtype S: 264

S'Value denotes a function with the following specification: 265

```
function S'Value(Arg : String)                                    266
  return S'Base
```

This function returns a value given an image of the value as a String, ignoring any leading or trailing spaces. See 3.5. 267

P'Version For a prefix P that statically denotes a program unit: 268/1

Yields a value of the predefined type String that identifies the version of the compilation unit that contains the declaration of the program unit. See E.3. 269

S'Wide_Image 270

For every subtype S of a type T:

S'Wide_Image denotes a function with the following specification: 271/5

```
function S'Wide_Image(Arg : S'Base)                                272/5
  return Wide_String
```

S'Wide_Image calls S'Put_Image passing *Arg* (which will typically store a sequence of character values in a text buffer) and then returns the result of retrieving the contents of that buffer with function Wide_Get. See 4.10. 273/5

X'Wide_Image 273.1/5

For a prefix X of a type T other than *universal_real* or *universal_fixed*:

X'Wide_Image denotes the result of calling function S'Wide_Image with *Arg* being X, where S is the nominal subtype of X. See 4.10. 273.2/5

S'Wide_Value 274

For every scalar subtype S:

S'Wide_Value denotes a function with the following specification: 275

```
function S'Wide_Value(Arg : Wide_String)                           276
  return S'Base
```

This function returns a value given an image of the value as a Wide_String, ignoring any leading or trailing spaces. See 3.5. 277

S'Wide_Wide_Image 277.1/2

For every subtype S of a type T:

S'Wide_Wide_Image denotes a function with the following specification: 277.2/5

```
function S'Wide_Wide_Image(Arg : S'Base)                           277.3/5
  return Wide_Wide_String
```

S'Wide_Wide_Image calls S'Put_Image passing *Arg* (which will typically store a sequence of character values in a text buffer) and then returns the result of retrieving the contents of that buffer with function Wide_Wide_Get. See 4.10. 277.4/5

X'Wide_Wide_Image 277.5/5

For a prefix X of a type T other than *universal_real* or *universal_fixed*:

X'Wide_Wide_Image denotes the result of calling function S'Wide_Wide_Image with *Arg* being X, where S is the nominal subtype of X. See 4.10. 277.6/5

277.7/2 S'Wide_Wide_Value

For every scalar subtype S:

277.8/2 S'Wide_Wide_Value denotes a function with the following specification:

277.9/2
```
function S'Wide_Wide_Value(Arg : Wide_Wide_String)
  return S'Base
```

277.10/2 This function returns a value given an image of the value as a Wide_Wide_String, ignoring any leading or trailing spaces. See 3.5.

277.11/2 S'Wide_Wide_Width

For every scalar subtype S:

277.12/5 S'Wide_Wide_Width denotes the maximum length of a Wide_Wide_String returned by S'Wide_Wide_Image over all values of the subtype S, assuming a default implementation of S'Put_Image. It denotes zero for a subtype that has a null range. Its type is *universal_integer*. See 3.5.

278 S'Wide_Width

For every scalar subtype S:

279/5 S'Wide_Width denotes the maximum length of a Wide_String returned by S'Wide_Image over all values of the subtype S, assuming a default implementation of S'Put_Image. It denotes zero for a subtype that has a null range. Its type is *universal_integer*. See 3.5.

280 S'Width For every scalar subtype S:

281/5 S'Width denotes the maximum length of a String returned by S'Image over all values of the subtype S, assuming a default implementation of S'Put_Image. It denotes zero for a subtype that has a null range. Its type is *universal_integer*. See 3.5.

282 S'Class'Write

For every subtype S'Class of a class-wide type *T*'Class:

283 S'Class'Write denotes a procedure with the following specification:

284/2
```
procedure S'Class'Write(
   Stream : not null access Ada.Streams.Root_Stream_Type'Class;
   Item   : in T'Class)
```

285 Dispatches to the subprogram denoted by the Write attribute of the specific type identified by the tag of Item. See 13.13.2.

286 S'Write For every subtype S of a specific type *T*:

287 S'Write denotes a procedure with the following specification:

288/2
```
procedure S'Write(
   Stream : not null access Ada.Streams.Root_Stream_Type'Class;
   Item : in T)
```

289 S'Write writes the value of *Item* to *Stream*. See 13.13.2.

Annex L
(informative)
Language-Defined Pragmas

This Annex summarizes the definitions given elsewhere of the language-defined pragmas. 1

pragma Admission_Policy (*policy*_identifier); — See D.4.1. 1.1/5

This paragraph was deleted. 2/5

pragma All_Calls_Remote[(*library_unit*_name)]; — See J.15.15. 2.1/5

Wording Changes from Ada 83

Pragmas List, Page, and Optimize are now officially defined in 2.8, “Pragmas”. 39.a

Annex M
(informative)
Summary of Documentation Requirements

{*AI05-0299-1*} {*AI12-0442-1*} The Ada language allows for certain target machine dependences in a controlled manner. Each Ada implementation is required to document many characteristics and properties of the target system. This Reference Manual contains specific documentation requirements. In addition, many characteristics that require documentation are identified throughout this Reference Manual as being implementation defined. Finally, this Reference Manual requires documentation of whether implementation advice is followed. The following subclauses provide summaries of these documentation requirements. 1/5

M.1 Specific Documentation Requirements

{*AI12-0442-1*} In addition to implementation-defined characteristics, each Ada implementation is required to document various properties of the implementation: 1/5

Ramification: Most of the items in this list require documentation only for implementations that conform to Specialized Needs Annexes. 1.a/2

- The behavior of implementations in implementation-defined situations shall be documented — see M.2 for a listing. See 1.1.3(19). 2/2
- The set of values that a user-defined Allocate procedure needs to accept for the Alignment parameter. How the standard storage pool is chosen, and how storage is allocated by standard storage pools. See 13.11(22). 3/2
- The algorithm used for random number generation, including a description of its period. See A.5.2(44). 4/2
- The minimum time interval between calls to the time-dependent Reset procedure that is guaranteed to initiate different random number sequences. See A.5.2(45). 5/2
- The conditions under which Io_Exceptions.Name_Error, Io_Exceptions.Use_Error, and Io_Exceptions.Device_Error are propagated. See A.13(15). 6/2
- The behavior of package Environment_Variables when environment variables are changed by external mechanisms. See A.17(30/2). 7/2
- The overhead of calling machine-code or intrinsic subprograms. See C.1(6). 8/2
- The types and attributes used in machine code insertions. See C.1(7). 9/2
- The subprogram calling conventions for all supported convention identifiers. See C.1(8/3). 10/2
- The mapping between the Link_Name or Ada designator and the external link name. See C.1(9). 11/2
- The treatment of interrupts. See C.3(22). 12/2
- The metrics for interrupt handlers. See C.3.1(16). 13/2
- If the Ceiling_Locking policy is in effect, the default ceiling priority for a protected object that specifies an interrupt handler aspect. See C.3.2(24/5). 14/3
- Any circumstances when the elaboration of a preelaborated package causes code to be executed. See C.4(12). 15/2
- Whether a partition can be restarted without reloading. See C.4(13). 16/2
- The effect of calling Current_Task from an entry body or interrupt handler. See C.7.1(19). 17/2

18/2 • For package Task_Attributes, limits on the number and size of task attributes, and how to configure any limits. See C.7.2(19).

19/2 • The metrics for the Task_Attributes package. See C.7.2(27).

20/2 • The details of the configuration used to generate the values of all metrics. See D(2).

21/2 • The maximum priority inversion a user task can experience from the implementation. See D.2.3(12/2).

22/2 • The amount of time that a task can be preempted for processing on behalf of lower-priority tasks. See D.2.3(13/2).

23/2 • The quantum values supported for round robin dispatching. See D.2.5(16/2).

24/2 • The accuracy of the detection of the exhaustion of the budget of a task for round robin dispatching. See D.2.5(17/2).

25/2 • Any conditions that cause the completion of the setting of the deadline of a task to be delayed for a multiprocessor. See D.2.6(32/2).

26/2 • Any conditions that cause the completion of the setting of the priority of a task to be delayed for a multiprocessor. See D.5.1(12.1/2).

27/2 • The metrics for Set_Priority. See D.5.1(14).

28/2 • The metrics for setting the priority of a protected object. See D.5.2(10).

29/2 • On a multiprocessor, any conditions that cause the completion of an aborted construct to be delayed later than what is specified for a single processor. See D.6(3).

30/2 • The metrics for aborts. See D.6(8).

31/2 • The values of Time_First, Time_Last, Time_Span_First, Time_Span_Last, Time_Span_Unit, and Tick for package Real_Time. See D.8(33).

32/2 • The properties of the underlying time base used in package Real_Time. See D.8(34).

33/2 • Any synchronization of package Real_Time with external time references. See D.8(35).

34/5 • Any aspects of the external environment that can interfere with package Real_Time. See D.8(36/5).

35/2 • The metrics for package Real_Time. See D.8(45).

36/2 • The minimum value of the delay expression of a delay_relative_statement that causes a task to actually be blocked. See D.9(7).

37/2 • The minimum difference between the value of the delay expression of a delay_until_statement and the value of Real_Time.Clock, that causes the task to actually be blocked. See D.9(8).

38/2 • The metrics for delay statements. See D.9(13).

39/2 • The upper bound on the duration of interrupt blocking caused by the implementation. See D.12(5).

40/2 • The metrics for entry-less protected objects. See D.12(12).

41/2 • The values of CPU_Time_First, CPU_Time_Last, CPU_Time_Unit, and CPU_Tick of package Execution_Time. See D.14(21/2).

42/3 • The properties of the mechanism used to implement package Execution_Time, including the values of the constants defined in the package. See D.14(22/2).

43/2 • The metrics for execution time. See D.14(27).

44/2 • The metrics for timing events. See D.15(24).

- The processor(s) on which the clock interrupt is handled; the processors on which each Interrupt_Id can be handled. See D.16.1(32). 44.1/3
- Whether the RPC-receiver is invoked from concurrent tasks, and if so, the number of such tasks. See E.5(25). 45/2
- Any techniques used to reduce cancellation errors in Numerics.Generic_Real_Arrays shall be documented. See G.3.1(86/2). 46/2
- Any techniques used to reduce cancellation errors in Numerics.Generic_Complex_Arrays shall be documented. See G.3.2(155/2). 47/2
- If a pragma Normalize_Scalars applies, the implicit initial values of scalar subtypes shall be documented. Such a value should be an invalid representation when possible; any cases when is it not shall be documented. See H.1(5/2). 48/2
- The range of effects for each bounded error and each unspecified effect. If the effects of a given erroneous construct are constrained, the constraints shall be documented. See H.2(1). 49/2
- For each inspection point, a mapping between each inspectable object and the machine resources where the object's value can be obtained shall be provided. See H.3.2(8). 50/2
- If a pragma Restrictions(No_Exceptions) is specified, the effects of all constructs where language-defined checks are still performed. See H.4(25). 51/2
- The interrupts to which a task entry may be attached. See J.7.1(12). 52/2
- The type of entry call invoked for an interrupt entry. See J.7.1(13). 53/2

M.2 Implementation-Defined Characteristics

{*AI12-0442-1*} The Ada language allows for certain machine dependences in a controlled manner. Each Ada implementation is required to document all implementation-defined characteristics: 1/5

Ramification: It need not document unspecified characteristics. 1.a

Some of the items in this list require documentation only for implementations that conform to Specialized Needs Annexes. 1.b

- Whether or not each recommendation given in Implementation Advice is followed — see M.3 for a listing. See 1.1.2(37). 2/2
- Capacity limitations of the implementation. See 1.1.3(3). 3
- Variations from the standard that are impractical to avoid given the implementation's execution environment. See 1.1.3(6). 4
- Which code_statements cause external interactions. See 1.1.3(10). 5
- The coded representation for the text of an Ada program. See 2.1(4/5). 6
- The semantics of an Ada program whose text is not in Normalization Form C. See 2.1(4.1/5). 6.1/5
- *This paragraph was deleted.* 7/2
- The representation for an end of line. See 2.2(2/3). 8
- Maximum supported line length and lexical element length. See 2.2(14). 9
- Implementation-defined pragmas. See 2.8(14). 10
- Effect of pragma Optimize. See 2.8(27). 11
- The message string associated with the Assertion_Error exception raised by the failure of a predicate check if there is no applicable Predicate_Failure aspect. See 3.2.4(31). 11.1/4
- The predefined integer types declared in Standard. See 3.5.4(25). 13

14 • Any nonstandard integer types and the operators defined for them. See 3.5.4(26/5).

15 • Any nonstandard real types and the operators defined for them. See 3.5.6(8/5).

16 • What combinations of requested decimal precision and range are supported for floating point types. See 3.5.7(7).

17 • The predefined floating point types declared in Standard. See 3.5.7(16/5).

18 • The *small* of an ordinary fixed point type. See 3.5.9(8/2).

19 • What combinations of *small*, range, and *digits* are supported for fixed point types. See 3.5.9(10).

20/2 • The result of Tags.Wide_Wide_Expanded_Name for types declared within an unnamed block_statement. See 3.9(10).

20.1/2 • The sequence of characters of the value returned by Tags.Expanded_Name (respectively, Tags.Wide_Expanded_Name) when some of the graphic characters of Tags.Wide_Wide_Expanded_Name are not defined in Character (respectively, Wide_Character). See 3.9(10.1/2).

21 • Implementation-defined attributes. See 4.1.4(12/5).

21.1/5 • The value of the parameter to Empty for some container_aggregates. See 4.3.5(40).

21.2/5 • The maximum number of chunks for a parallel reduction expression without a chunk_specification. See 4.5.10(21).

21.3/2 • Rounding of real static expressions which are exactly half-way between two machine numbers. See 4.9(38/2).

21.4/5 • The maximum number of chunks for a parallel generalized iterator without a chunk_specification. See 5.5.2(10).

21.5/5 • The number of chunks for an array component iterator. See 5.5.2(11).

21.6/5 • Any extensions of the Global aspect. See 6.1.2(43).

21.7/5 • The circumstances in which the implementation passes in the null value for a view conversion of an access type used as an **out** parameter. See 6.4.1(19/5).

21.8/5 • Any extensions of the Default_Initial_Condition aspect. See 7.3.3(11).

22 • Any implementation-defined time types. See 9.6(6/3).

23 • The time base associated with relative delays. See 9.6(20).

24 • The time base of the type Calendar.Time. See 9.6(23).

25/2 • The time zone used for package Calendar operations. See 9.6(24/2).

26 • Any limit on delay_until_statements of select_statements. See 9.6(29).

26.1/2 • The result of Calendar.Formatting.Image if its argument represents more than 100 hours. See 9.6.1(86/5).

27/3 • *This paragraph was deleted.*

27.1/5 • Implementation-defined conflict check policies. See 9.10.1(5).

28 • The representation for a compilation. See 10.1(2).

29 • Any restrictions on compilations that contain multiple compilation_units. See 10.1(4).

30 • The mechanisms for creating an environment and for adding and replacing compilation units. See 10.1.4(3/2).

30.1/2 • The mechanisms for adding a compilation unit mentioned in a limited_with_clause to an environment. See 10.1.4(3).

- The manner of explicitly assigning library units to a partition. See 10.2(2). 31
- The implementation-defined means, if any, of specifying which compilation units are needed by a given compilation unit. See 10.2(2). 32
- The manner of designating the main subprogram of a partition. See 10.2(7). 33
- The order of elaboration of library_items. See 10.2(18). 34
- Parameter passing and function return for the main subprogram. See 10.2(21). 35
- The mechanisms for building and running partitions. See 10.2(24/5). 36
- The details of program execution, including program termination. See 10.2(25). 37
- The semantics of any nonactive partitions supported by the implementation. See 10.2(28/3). 38
- The information returned by Exception_Message. See 11.4.1(10.1/4). 39
- The result of Exceptions.Wide_Wide_Exception_Name for exceptions declared within an unnamed block_statement. See 11.4.1(12). 40/2
- The sequence of characters of the value returned by Exceptions.Exception_Name (respectively, Exceptions.Wide_Exception_Name) when some of the graphic characters of Exceptions.Wide_Wide_Exception_Name are not defined in Character (respectively, Wide_Character). See 11.4.1(12.1/2). 40.1/2
- The information returned by Exception_Information. See 11.4.1(13/2). 41
- Implementation-defined *policy*_identifiers and *assertion*_aspect_marks allowed in a pragma Assertion_Policy. See 11.4.2(9/5). 41.1/3
- The default assertion policy. See 11.4.2(10). 41.2/2
- Implementation-defined check names. See 11.5(27). 42
- Existence and meaning of second parameter of pragma Unsuppress. See 11.5(27.1/2). 42.1/2
- The cases that cause conflicts between the representation of the ancestors of a type_declaration. See 13.1(13.1/3). 42.2/2
- The interpretation of each representation aspect. See 13.1(20). 43/3
- Any restrictions placed upon the specification of representation aspects. See 13.1(20). 44/3
- Implementation-defined aspects, including the syntax for specifying such aspects and the legality rules for such aspects. See 13.1.1(38). 44.1/3
- The set of machine scalars. See 13.3(8.1/3). 44.2/2
- The meaning of Size for indefinite subtypes. See 13.3(48). 45
- The meaning of Object_Size for indefinite subtypes. See 13.3(58). 45.1/5
- The default external representation for a type tag. See 13.3(75/3). 46
- What determines whether a compilation unit is the same in two different partitions. See 13.3(76). 47
- Implementation-defined components. See 13.5.1(15). 48
- If Word_Size = Storage_Unit, the default bit ordering. See 13.5.3(5). 49
- The contents of the visible part of package System. See 13.7(2). 50/2
- The range of Storage_Elements.Storage_Offset, the modulus of Storage_Elements.Storage_-Element, and the declaration of Storage_Elements.Integer_Address. See 13.7.1(11). 50.1/2
- The contents of the visible part of package System.Machine_Code, and the meaning of code_statements. See 13.8(7). 51

51.1/2 • The result of unchecked conversion for instances with scalar result types whose result is not defined by the language. See 13.9(11).

52/2 • The effect of unchecked conversion for instances with nonscalar result types whose effect is not defined by the language. See 13.9(11).

53/2 • *This paragraph was deleted.*

54 • Whether or not the implementation provides user-accessible names for the standard pool type(s). See 13.11(17).

55/2 • The meaning of Storage_Size when neither the Storage_Size nor the Storage_Pool is specified for an access type. See 13.11(18).

56/2 • *This paragraph was deleted.*

56.1/4 • The effect of specifying aspect Default_Storage_Pool on an instance of a language-defined generic unit. See 13.11.3(5).

57/3 • *This paragraph was deleted.*

57.1/3 • Implementation-defined restrictions allowed in a pragma Restrictions. See 13.12(8.7/3).

58 • The consequences of violating limitations on Restrictions pragmas. See 13.12(9).

58.1/3 • Implementation-defined usage profiles allowed in a pragma Profile. See 13.12(15).

59/2 • The contents of the stream elements read and written by the Read and Write attributes of elementary types. See 13.13.2(9).

60 • The names and characteristics of the numeric subtypes declared in the visible part of package Standard. See A.1(3).

60.1/2 • The values returned by Strings.Hash. See A.4.9(3/2).

60.2/5 • The value returned by a call to a Text_Buffer Get procedure if any character in the returned sequence is not defined in Character. See A.4.12(34).

60.3/5 • The value returned by a call to a Text_Buffer Wide_Get procedure if any character in the returned sequence is not defined in Wide_Character. See A.4.12(34).

61 • The accuracy actually achieved by the elementary functions. See A.5.1(1).

62 • The sign of a zero result from some of the operators or functions in Numerics.Generic_Elementary_Functions, when Float_Type'Signed_Zeros is True. See A.5.1(46).

63 • The value of Numerics.Float_Random.Max_Image_Width. See A.5.2(27).

64 • The value of Numerics.Discrete_Random.Max_Image_Width. See A.5.2(27).

65/2 • *This paragraph was deleted.*

66 • The string representation of a random number generator's state. See A.5.2(38).

67/2 • *This paragraph was deleted.*

68 • The values of the Model_Mantissa, Model_Emin, Model_Epsilon, Model, Safe_First, and Safe_Last attributes, if the Numerics Annex is not supported. See A.5.3(72).

69/2 • *This paragraph was deleted.*

70 • The value of Buffer_Size in Storage_IO. See A.9(10).

71/2 • The external files associated with the standard input, standard output, and standard error files. See A.10(5).

72 • The accuracy of the value produced by Put. See A.10.9(36).

- Current size for a stream file for which positioning is not supported. See A.12.1(1.1/1). 72.1/1
- The meaning of Argument_Count, Argument, and Command_Name for package Command_Line. The bounds of type Command_Line.Exit_Status. See A.15(1). 73/2
- The interpretation of file names and directory names. See A.16(46/2). 73.1/2
- The maximum value for a file size in Directories. See A.16(87/2). 73.2/2
- The result for Directories.Size for a directory or special file. See A.16(93/2). 73.3/2
- The result for Directories.Modification_Time for a directory or special file. See A.16(95/2). 73.4/2
- The interpretation of a nonnull search pattern in Directories. See A.16(104/3). 73.5/2
- The results of a Directories search if the contents of the directory are altered while a search is in progress. See A.16(110/3). 73.6/2
- The definition and meaning of an environment variable. See A.17(1/2). 73.7/2
- The circumstances where an environment variable cannot be defined. See A.17(16/2). 73.8/2
- Environment names for which Set has the effect of Clear. See A.17(17/2). 73.9/2
- The value of Containers.Hash_Type'Modulus. The value of Containers.Count_Type'Last. See A.18.1(7/2). 73.10/2
- Implementation-defined convention names. See B.1(11/3). 74
- The meaning of link names. See B.1(36). 75
- The manner of choosing link names when neither the link name nor the address of an imported or exported entity is specified. See B.1(36). 76
- The effect of pragma Linker_Options. See B.1(37). 77
- The contents of the visible part of package Interfaces and its language-defined descendants. See B.2(1). 78
- Implementation-defined children of package Interfaces. See B.2(11). 79/2
- The definitions of certain types and constants in Interfaces.C. See B.3(41). 79.1/2
- The types Floating, Long_Floating, Binary, Long_Binary, Decimal_Element, and COBOL_Character; and the initializations of the variables Ada_To_COBOL and COBOL_To_Ada, in Interfaces.COBOL. See B.4(50). 80/1
- The types Fortran_Integer, Real, Double_Precision, and Character_Set in Interfaces.Fortran. See B.5(17). 80.1/1
- Implementation-defined intrinsic subprograms. See C.1(1/3). 81/2
- *This paragraph was deleted.* 82/2
- *This paragraph was deleted.* 83/2
- Any restrictions on a protected procedure or its containing type when an aspect Attach_handler or Interrupt_Handler is specified. See C.3.1(17). 83.1/3
- Any other forms of interrupt handler supported by the Attach_Handler and Interrupt_Handler aspects. See C.3.1(19). 83.2/3
- *This paragraph was deleted.* 84/2
- The semantics of some attributes and functions of an entity for which aspect Discard_Names is True. See C.5(7). 85/4
- The modulus and size of Test_and_Set_Flag. See C.6.3(8). 85.1/5

85.2/5 • The value used to represent the set value for Atomic_Test_and_Set. See C.6.3(10).

86 • The result of the Task_Identification.Image attribute. See C.7.1(7).

87/2 • The value of Current_Task when in a protected entry, interrupt handler, or finalization of a task attribute. See C.7.1(17/3).

88/2 • *This paragraph was deleted.*

88.1/1 • Granularity of locking for Task_Attributes. See C.7.2(16/1).

89/2 • *This paragraph was deleted.*

90/2 • *This paragraph was deleted.*

91 • The declarations of Any_Priority and Priority. See D.1(11).

92 • Implementation-defined execution resources. See D.1(15/5).

93 • Whether, on a multiprocessor, a task that is waiting for access to a protected object keeps its processor busy. See D.2.1(3).

94/2 • The effect of implementation-defined execution resources on task dispatching. See D.2.1(9/2).

95/2 • *This paragraph was deleted.*

96/2 • *This paragraph was deleted.*

97/2 • Implementation defined task dispatching policies. See D.2.2(18).

97.1/2 • The value of Default_Quantum in Dispatching.Round_Robin. See D.2.5(4).

98 • Implementation-defined *policy*_identifiers allowed in a pragma Locking_Policy. See D.3(4).

98.1/2 • The locking policy if no Locking_Policy pragma applies to any unit of a partition. See D.3(6).

99 • Default ceiling priorities. See D.3(10/4).

100 • The ceiling of any protected object used internally by the implementation. See D.3(16).

101 • Implementation-defined queuing policies. See D.4(1/5).

101.1/5 • Implementation-defined admission policies. See D.4.1(1).

102/2 • *This paragraph was deleted.*

103 • Any operations that implicitly require heap storage allocation. See D.7(8).

103.1/4 • When restriction No_Dynamic_CPU_Assignment applies to a partition, the processor on which a task with a CPU value of a Not_A_Specific_CPU will execute. See D.7(10).

103.2/2 • When restriction No_Task_Termination applies to a partition, what happens when a task terminates. See D.7(15.1/2).

103.3/2 • The behavior when restriction Max_Storage_At_Blocking is violated. See D.7(17/1).

103.4/2 • The behavior when restriction Max_Asynchronous_Select_Nesting is violated. See D.7(18/1).

103.5/2 • The behavior when restriction Max_Tasks is violated. See D.7(19).

104/2 • Whether the use of pragma Restrictions results in a reduction in program code or data size or execution time. See D.7(20).

105/2 • *This paragraph was deleted.*

106/2 • *This paragraph was deleted.*

106.1/3 • The value of Barrier_Limit'Last in Synchronous_Barriers. See D.10.1(4/3).

106.2/3 • When an aborted task that is waiting on a Synchronous_Barrier is aborted. See D.10.1(13/3).

- *This paragraph was deleted.* 107/2
- The value of Min_Handler_Ceiling in Execution_Time.Group_Budgets. See D.14.2(7/2). 107.1/3
- The value of CPU_Range'Last in System.Multiprocessors. See D.16(4/3). 107.2/3
- The processor on which the environment task executes in the absence of a value for the aspect CPU. See D.16(13/3). 107.3/3
- The means for creating and executing distributed programs. See E(5). 108
- Any events that can result in a partition becoming inaccessible. See E.1(7). 109
- The scheduling policies, treatment of priorities, and management of shared resources between partitions in certain cases. See E.1(11). 110
- *This paragraph was deleted.* 111/1
- Whether the execution of the remote subprogram is immediately aborted as a result of cancellation. See E.4(13). 112
- The range of type System.RPC.Partition_Id. See E.5(14). 112.1/2
- *This paragraph was deleted.* 113/2
- Implementation-defined interfaces in the PCS. See E.5(26). 114
- The values of named numbers in the package Decimal. See F.2(7). 115
- The value of Max_Picture_Length in the package Text_IO.Editing See F.3.3(16). 116
- The value of Max_Picture_Length in the package Wide_Text_IO.Editing See F.3.4(5). 117
- The value of Max_Picture_Length in the package Wide_Wide_Text_IO.Editing See F.3.5(5). 117.1/2
- The accuracy actually achieved by the complex elementary functions and by other complex arithmetic operations. See G.1(1). 118
- The sign of a zero result (or a component thereof) from any operator or function in Numerics.Generic_Complex_Types, when Real'Signed_Zeros is True. See G.1.1(53). 119
- The sign of a zero result (or a component thereof) from any operator or function in Numerics.Generic_Complex_Elementary_Functions, when Complex_Types.Real'Signed_Zeros is True. See G.1.2(45). 120
- Whether the strict mode or the relaxed mode is the default. See G.2(2). 121
- The result interval in certain cases of fixed-to-float conversion. See G.2.1(10). 122
- The result of a floating point arithmetic operation in overflow situations, when the Machine_Overflows attribute of the result type is False. See G.2.1(13). 123
- The result interval for division (or exponentiation by a negative exponent), when the floating point hardware implements division as multiplication by a reciprocal. See G.2.1(16). 124
- The definition of *close result set*, which determines the accuracy of certain fixed point multiplications and divisions. See G.2.3(5). 125
- Conditions on a *universal_real* operand of a fixed point multiplication or division for which the result shall be in the *perfect result set*. See G.2.3(22). 126
- The result of a fixed point arithmetic operation in overflow situations, when the Machine_Overflows attribute of the result type is False. See G.2.3(27). 127
- The result of an elementary function reference in overflow situations, when the Machine_Overflows attribute of the result type is False. See G.2.4(4). 128

129 • The value of the *angle threshold*, within which certain elementary functions, complex arithmetic operations, and complex elementary functions yield results conforming to a maximum relative error bound. See G.2.4(10).

130 • The accuracy of certain elementary functions for parameters beyond the angle threshold. See G.2.4(10).

131 • The result of a complex arithmetic operation or complex elementary function reference in overflow situations, when the Machine_Overflows attribute of the corresponding real type is False. See G.2.6(5).

132 • The accuracy of certain complex arithmetic operations and certain complex elementary functions for parameters (or components thereof) beyond the angle threshold. See G.2.6(8).

132.1/2 • The accuracy requirements for the subprograms Solve, Inverse, Determinant, Eigenvalues and Eigensystem for type Real_Matrix. See G.3.1(81/2).

132.2/2 • The accuracy requirements for the subprograms Solve, Inverse, Determinant, Eigenvalues and Eigensystem for type Complex_Matrix. See G.3.2(149/2).

133/2 • *This paragraph was deleted.*

134/2 • *This paragraph was deleted.*

134.1/5 • The consequences of violating No_Hidden_Indirect_Globals. See H.4(23.9/5).

135/2 • *This paragraph was deleted.*

136/2 • *This paragraph was deleted.*

136.1/2 • Implementation-defined *policy_*identifiers allowed in a pragma Partition_Elaboration_Policy. See H.6(4/2).

M.3 Implementation Advice

1/5 {*AI12-0442-1*} This Reference Manual sometimes gives advice about handling certain target machine dependences. Each Ada implementation is required to document whether that advice is followed:

1.a/2 **Ramification:** Some of the items in this list require documentation only for implementations that conform to Specialized Needs Annexes.

2/2 • Program_Error should be raised when an unsupported Specialized Needs Annex feature is used at run time. See 1.1.3(20).

3/2 • Implementation-defined extensions to the functionality of a language-defined library unit should be provided by adding children to the library unit. See 1.1.3(21).

4/2 • If a bounded error or erroneous execution is detected, Program_Error should be raised. See 1.1.5(12).

5/2 • Implementation-defined pragmas should have no semantic effect for error-free programs. See 2.8(16/3).

6/2 • Implementation-defined pragmas should not make an illegal program legal, unless they complete a declaration or configure the library_items in an environment. See 2.8(19).

7/2 • Long_Integer should be declared in Standard if the target supports 32-bit arithmetic. No other named integer subtypes should be declared in Standard. See 3.5.4(28).

8/2 • For a two's complement target, modular types with a binary modulus up to System.Max_Int*2+2 should be supported. A nonbinary modulus up to Integer'Last should be supported. See 3.5.4(29).

- Program_Error should be raised for the evaluation of S'Pos for an enumeration type, if the value of the operand does not correspond to the internal code for any enumeration literal of the type. See 3.5.5(8). 9/2
- Long_Float should be declared in Standard if the target supports 11 or more digits of precision. No other named float subtypes should be declared in Standard. See 3.5.7(17). 10/2
- Multidimensional arrays should be represented in row-major order, unless the array has convention Fortran. See 3.6.2(11/3). 11/2
- Tags.Internal_Tag should return the tag of a type, if one exists, whose innermost master is a master of the point of the function call. See 3.9(26.1/3). 12/3
- A real static expression with a nonformal type that is not part of a larger static expression should be rounded the same as the target system. See 4.9(38.1/2). 13/2
- For each language-defined private type T, T'Image should generate an image that would be meaningful based only on the relevant public interfaces. See 4.10(56). 13.1/5
- The value of Duration'Small should be no greater than 100 microseconds. See 9.6(30). 14/2
- The time base for delay_relative_statements should be monotonic. See 9.6(31/5). 15/2
- Leap seconds should be supported if the target system supports them. Otherwise, operations in Calendar.Formatting should return results consistent with no leap seconds. See 9.6.1(89/2). 16/2
- *This paragraph was deleted.* 17/5
- A type declared in a preelaborated package should have the same representation in every elaboration of a given version of the package. See 10.2.1(12). 18/2
- Exception_Information should provide information useful for debugging, and should include the Exception_Name and Exception_Message. See 11.4.1(19). 19/2
- Exception_Message by default should be short, provide information useful for debugging, and should not include the Exception_Name. See 11.4.1(19). 20/2
- Code executed for checks that have been suppressed should be minimized. See 11.5(28). 21/2
- The recommended level of support for all representation items should be followed. See 13.1(28/5). 22/2
- Storage allocated to objects of a packed type should be minimized. See 13.2(6). 23/2
- The recommended level of support for the Pack aspect should be followed. See 13.2(9). 24/3
- For an array X, X'Address should point at the first component of the array rather than the array bounds. See 13.3(14). 25/2
- The recommended level of support for the Address attribute should be followed. See 13.3(19). 26/2
- For any tagged specific subtype *S*, *S*'Class'Alignment should equal *S*'Alignment. See 13.3(28). 26.1/3
- The recommended level of support for the Alignment attribute should be followed. See 13.3(35). 27/2
- The Size of an array object should not include its bounds. See 13.3(41.1/2). 28/2
- If the Size of a subtype is nonconfirming and allows for efficient independent addressability, then the Object_Size of the subtype (unless otherwise specified) should equal the Size of the subtype. See 13.3(52). 29/5
- A Size clause on a composite subtype should not affect the internal layout of components. See 13.3(53). 30/2
- The recommended level of support for the Size attribute should be followed. See 13.3(56). 31/2

31.1/5 • An Object_Size clause on a composite type should not affect the internal layout of components. See 13.3(58).

31.2/5 • If S is a definite first subtype for which Object_Size is not specified, S'Object_Size should be the smallest multiple of the storage element size larger than or equal to S'Size that is consistent with the alignment of S. See 13.3(58).

31.3/5 • The recommended level of support for the Object_Size attribute should be followed. See 13.3(58).

31.4/5 • The Size of most objects of a subtype should equal the Object_Size of the subtype. See 13.3(58).

32/2 • The recommended level of support for the Component_Size attribute should be followed. See 13.3(73).

33/2 • The recommended level of support for enumeration_representation_clauses should be followed. See 13.4(10).

34/2 • The recommended level of support for record_representation_clauses should be followed. See 13.5.1(22).

35/2 • If a component is represented using a pointer to the actual data of the component which is contiguous with the rest of the object, then the storage place attributes should reflect the place of the actual data. If a component is allocated discontiguously from the rest of the object, then a warning should be generated upon reference to one of its storage place attributes. See 13.5.2(5).

36/2 • The recommended level of support for the nondefault bit ordering should be followed. See 13.5.3(8).

37/2 • Type System.Address should be a private type. See 13.7(37).

38/2 • Operations in System and its children should reflect the target environment; operations that do not make sense should raise Program_Error. See 13.7.1(16).

39/2 • Since the Size of an array object generally does not include its bounds, the bounds should not be part of the converted data in an instance of Unchecked_Conversion. See 13.9(14/2).

40/2 • There should not be unnecessary runtime checks on the result of an Unchecked_Conversion; the result should be returned by reference when possible. Restrictions on Unchecked_Conversions should be avoided. See 13.9(15).

41/2 • The recommended level of support for Unchecked_Conversion should be followed. See 13.9(17).

42/2 • Any cases in which heap storage is dynamically allocated other than as part of the evaluation of an allocator should be documented. See 13.11(23).

43/2 • A default storage pool for an access-to-constant type should not have overhead to support deallocation of individual objects. See 13.11(24).

44/2 • Usually, a storage pool for an access discriminant or access parameter should be created at the point of an allocator, and be reclaimed when the designated object becomes inaccessible. For other anonymous access types, the pool should be created at the point where the type is elaborated and may have no mechanism for the deallocation of individual objects. See 13.11(25).

45/2 • For a standard storage pool, an instance of Unchecked_Deallocation should actually reclaim the storage. See 13.11.2(17).

45.1/3 • A call on an instance of Unchecked_Deallocation with a nonnull access value should raise Program_Error if the actual access type of the instance is a type for which the Storage_Size has been specified to be zero or is defined by the language to be zero. See 13.11.2(17.1/3).

45.2/5 • Streams.Storage.Bounded.Stream_Type objects should be implemented without implicit pointers or dynamic allocation. See 13.13.1(37).

- If not specified, the value of Stream_Size for an elementary type should be the number of bits that corresponds to the minimum number of stream elements required by the first subtype of the type, rounded up to the nearest factor or multiple of the word size that is also a multiple of the stream element size. See 13.13.2(1.6/2). 46/2
- The recommended level of support for the Stream_Size attribute should be followed. See 13.13.2(1.8/2). 47/2
- If an implementation provides additional named predefined integer types, then the names should end with "Integer". If an implementation provides additional named predefined floating point types, then the names should end with "Float". See A.1(52). 48/2
- Implementation-defined operations on Wide_Character, Wide_String, Wide_Wide_Character, and Wide_Wide_String should be child units of Wide_Characters or Wide_Wide_Characters. See A.3.1(7/3). 49/2
- The string returned by Wide_Characters.Handling.Character_Set_Version should include either "10646:" or "Unicode". See A.3.5(62). 49.1/3
- Bounded string objects should not be implemented by implicit pointers and dynamic allocation. See A.4.4(106). 50/2
- Strings.Hash should be good a hash function, returning a wide spread of values for different string values, and similar strings should rarely return the same value. See A.4.9(12/2). 51/2
- If an implementation supports other string encoding schemes, a child of Ada.Strings similar to UTF_Encoding should be defined. See A.4.11(107/3). 51.1/3
- Bounded buffer objects should be implemented without dynamic allocation. See A.4.12(36). 51.2/5
- Any storage associated with an object of type Generator of the random number packages should be reclaimed on exit from the scope of the object. See A.5.2(46). 52/2
- Each value of Initiator passed to Reset for the random number packages should initiate a distinct sequence of random numbers, or, if that is not possible, be at least a rapidly varying function of the initiator value. See A.5.2(47). 53/2
- Get_Immediate should be implemented with unbuffered input; input should be available immediately; line-editing should be disabled. See A.10.7(23). 54/2
- Package Directories.Information should be provided to retrieve other information about a file. See A.16(124/2). 55/2
- Directories.Start_Search and Directories.Search should raise Name_Error for malformed patterns. See A.16(125). 56/3
- Directories.Rename should be supported at least when both New_Name and Old_Name are simple names and New_Name does not identify an existing external file. See A.16(126/2). 57/2
- Directories.Hierarchical_File_Names should be provided for systems with hierarchical file naming, and should not be provided on other systems. See A.16.1(36/3). 57.1/3
- If the execution environment supports subprocesses, the current environment variables should be used to initialize the environment variables of a subprocess. See A.17(32/2). 58/2
- Changes to the environment variables made outside the control of Environment_Variables should be reflected immediately. See A.17(33/2). 59/2
- Containers.Hash_Type'Modulus should be at least 2**32. Containers.Count_Type'Last should be at least 2**31–1. See A.18.1(8/2). 60/2
- The worst-case time complexity of Element for Containers.Vector should be $O(\log N)$. See A.18.2(256/2). 61/2

62/2 • The worst-case time complexity of Append with Count = 1 when *N* is less than the capacity for Containers.Vector should be *O*(log *N*). See A.18.2(257/2).

63/2 • The worst-case time complexity of Prepend with Count = 1 and Delete_First with Count=1 for Containers.Vectors should be *O*(*N* log *N*). See A.18.2(258/2).

64/2 • The worst-case time complexity of a call on procedure Sort of an instance of Containers.Vectors.Generic_Sorting should be *O*(*N***2), and the average time complexity should be better than *O*(*N***2). See A.18.2(259/2).

65/2 • Containers.Vectors.Generic_Sorting.Sort and Containers.Vectors.Generic_Sorting.Merge should minimize copying of elements. See A.18.2(260/2).

66/2 • Containers.Vectors.Move should not copy elements, and should minimize copying of internal data structures. See A.18.2(261/2).

67/2 • If an exception is propagated from a vector operation, no storage should be lost, nor any elements removed from a vector unless specified by the operation. See A.18.2(262/2).

68/2 • The worst-case time complexity of Element, Insert with Count=1, and Delete with Count=1 for Containers.Doubly_Linked_Lists should be *O*(log *N*). See A.18.3(160/2).

69/2 • A call on procedure Sort of an instance of Containers.Doubly_Linked_Lists.Generic_Sorting should have an average time complexity better than *O*(*N***2) and worst case no worse than *O*(*N***2). See A.18.3(161/2).

70/2 • Containers.Doubly_Linked_Lists.Move should not copy elements, and should minimize copying of internal data structures. See A.18.3(162/2).

71/2 • If an exception is propagated from a list operation, no storage should be lost, nor any elements removed from a list unless specified by the operation. See A.18.3(163/2).

72/2 • Move for a map should not copy elements, and should minimize copying of internal data structures. See A.18.4(83/2).

73/2 • If an exception is propagated from a map operation, no storage should be lost, nor any elements removed from a map unless specified by the operation. See A.18.4(84/2).

74/2 • The average time complexity of Element, Insert, Include, Replace, Delete, Exclude, and Find operations that take a key parameter for Containers.Hashed_Maps should be *O*(log *N*). The average time complexity of the subprograms of Containers.Hashed_Maps that take a cursor parameter should be *O*(1). The average time complexity of Containers.Hashed_Maps.Reserve_Capacity should be *O*(*N*). See A.18.5(62/2).

75/2 • The worst-case time complexity of Element, Insert, Include, Replace, Delete, Exclude, and Find operations that take a key parameter for Containers.Ordered_Maps should be *O*((log *N*)**2) or better. The worst-case time complexity of the subprograms of Containers.Ordered_Maps that take a cursor parameter should be *O*(1). See A.18.6(95/2).

76/2 • Move for sets should not copy elements, and should minimize copying of internal data structures. See A.18.7(104/2).

77/2 • If an exception is propagated from a set operation, no storage should be lost, nor any elements removed from a set unless specified by the operation. See A.18.7(105/2).

78/2 • The average time complexity of the Insert, Include, Replace, Delete, Exclude, and Find operations of Containers.Hashed_Sets that take an element parameter should be *O*(log *N*). The average time complexity of the subprograms of Containers.Hashed_Sets that take a cursor parameter should be *O*(1). The average time complexity of Containers.Hashed_Sets.-Reserve_Capacity should be *O*(*N*). See A.18.8(88/2).

79/2 • The worst-case time complexity of the Insert, Include, Replace, Delete, Exclude, and Find operations of Containers.Ordered_Sets that take an element parameter should be *O*((log *N*)**2).

The worst-case time complexity of the subprograms of Containers.Ordered_Sets that take a cursor parameter should be *O*(1). See A.18.9(116/2).

- The worst-case time complexity of the Element, Parent, First_Child, Last_Child, Next_Sibling, Previous_Sibling, Insert_Child with Count=1, and Delete operations of Containers.Multiway_Trees should be *O*(log *N*). See A.18.10(231/3). 79.1/3
- Containers.Multiway_Trees.Move should not copy elements, and should minimize copying of internal data structures. See A.18.10(232/3). 79.2/3
- If an exception is propagated from a tree operation, no storage should be lost, nor any elements removed from a tree unless specified by the operation. See A.18.10(233/3). 79.3/3
- Move and Swap in Containers.Indefinite_Holders should not copy any elements, and should minimize copying of internal data structures. See A.18.18(73/5). 79.4/5
- If an exception is propagated from a holder operation, no storage should be lost, nor should the element be removed from a holder container unless specified by the operation. See A.18.18(74/3). 79.5/3
- Bounded vector objects should be implemented without implicit pointers or dynamic allocation. See A.18.19(16/3). 79.6/3
- The implementation advice for procedure Move to minimize copying does not apply to bounded vectors. See A.18.19(17/3). 79.7/3
- Bounded list objects should be implemented without implicit pointers or dynamic allocation. See A.18.20(19/3). 79.8/3
- The implementation advice for procedure Move to minimize copying does not apply to bounded lists. See A.18.20(20/3). 79.9/3
- Bounded hashed map objects should be implemented without implicit pointers or dynamic allocation. See A.18.21(21/3). 79.10/3
- The implementation advice for procedure Move to minimize copying does not apply to bounded hashed maps. See A.18.21(22/3). 79.11/3
- Bounded ordered map objects should be implemented without implicit pointers or dynamic allocation. See A.18.22(18/3). 79.12/3
- The implementation advice for procedure Move to minimize copying does not apply to bounded ordered maps. See A.18.22(19/3). 79.13/3
- Bounded hashed set objects should be implemented without implicit pointers or dynamic allocation. See A.18.23(20/3). 79.14/3
- The implementation advice for procedure Move to minimize copying does not apply to bounded hashed sets. See A.18.23(21/3). 79.15/3
- Bounded ordered set objects should be implemented without implicit pointers or dynamic allocation. See A.18.24(17/3). 79.16/3
- The implementation advice for procedure Move to minimize copying does not apply to bounded ordered sets. See A.18.24(18/3). 79.17/3
- Bounded tree objects should be implemented without implicit pointers or dynamic allocation. See A.18.25(19/3). 79.18/3
- The implementation advice for procedure Move to minimize copying does not apply to bounded trees. See A.18.25(20/3). 79.19/3
- Containers.Generic_Array_Sort and Containers.Generic_Constrained_Array_Sort should have an average time complexity better than *O*(*N***2) and worst case no worse than *O*(*N***2). See A.18.26(10/2). 80/2

81/2 • Containers.Generic_Array_Sort and Containers.Generic_Constrained_Array_Sort should minimize copying of elements. See A.18.26(11/2).

81.1/3 • Containers.Generic_Sort should have an average time complexity better than *O*(*N***2) and worst case no worse than *O*(*N***2). See A.18.26(12/3).

81.2/3 • Containers.Generic_Sort should minimize calls to the generic formal Swap. See A.18.26(13/3).

81.3/3 • Bounded queue objects should be implemented without implicit pointers or dynamic allocation. See A.18.29(13/3).

81.4/3 • Bounded priority queue objects should be implemented without implicit pointers or dynamic allocation. See A.18.31(14/3).

81.5/5 • Bounded holder objects should be implemented without dynamic allocation. See A.18.32(15/5).

82/3 • If Export is supported for a language, the main program should be able to be written in that language. Subprograms named "adainit" and "adafinal" should be provided for elaboration and finalization of the environment task. See B.1(39/3).

83/3 • Automatic elaboration of preelaborated packages should be provided when specifying the Export aspect as True is supported. See B.1(40/3).

84/3 • For each supported convention *L* other than Intrinsic, specifying the aspects Import and Export should be supported for objects of *L*-compatible types and for subprograms, and aspect Convention should be supported for *L*-eligible types and for subprograms. See B.1(41/5).

85/2 • If an interface to C, COBOL, or Fortran is provided, the corresponding package or packages described in Annex B, “Interface to Other Languages” should also be provided. See B.2(13/3).

86/2 • The constants nul, wide_nul, char16_nul, and char32_nul in package Interfaces.C should have a representation of zero. See B.3(62.5/3).

87/2 • If C interfacing is supported, the interface correspondences between Ada and C should be supported. See B.3(71).

87.1/5 • If the C implementation supports unsigned long long and long long, unsigned_long_long and long_long should be supported. See B.3(71).

88/2 • If COBOL interfacing is supported, the interface correspondences between Ada and COBOL should be supported. See B.4(98).

89/2 • If Fortran interfacing is supported, the interface correspondences between Ada and Fortran should be supported. See B.5(26).

90/2 • The machine code or intrinsics support should allow access to all operations normally available to assembly language programmers for the target environment. See C.1(3).

91/2 • Interface to assembler should be supported; the default assembler should be associated with the convention identifier Assembler. See C.1(4/3).

92/5 • If an entity is exported to assembly language, then the implementation should allocate it at an addressable location even if not otherwise referenced from the Ada code. A call to a machine code or assembler subprogram should be treated as if it can read or update every object that is specified as exported. See C.1(5).

93/2 • Little or no overhead should be associated with calling intrinsic and machine-code subprograms. See C.1(10).

94/2 • Intrinsic subprograms should be provided to access any machine operations that provide special capabilities or efficiency not normally available. See C.1(16).

- If the Ceiling_Locking policy is not in effect and the target system allows for finer-grained control of interrupt blocking, a means for the application to specify which interrupts are to be blocked during protected actions should be provided. See C.3(28/2). 95/2
- Interrupt handlers should be called directly by the hardware. See C.3.1(20). 96/2
- Violations of any implementation-defined restrictions on interrupt handlers should be detected before run time. See C.3.1(21). 97/2
- If implementation-defined forms of interrupt handler procedures are supported, then for each such form of a handler, a type analogous to Parameterless_Handler should be specified in a child package of Interrupts, with the same operations as in the predefined package Interrupts. See C.3.2(25). 98/2
- Preelaborated packages should be implemented such that little or no code is executed at run time for the elaboration of entities. See C.4(14). 99/2
- If aspect Discard_Names is True for an entity, then the amount of storage used for storing names associated with that entity should be reduced. See C.5(8/4). 100/4
- A load or store of a volatile object whose size is a multiple of System.Storage_Unit and whose alignment is nonzero, should be implemented by accessing exactly the bits of the object and no others. See C.6(22/5). 101/2
- A load or store of an atomic object should be implemented by a single load or store instruction. See C.6(23/2). 102/2
- If the target domain requires deterministic memory use at run time, storage for task attributes should be pre-allocated statically and the number of attributes pre-allocated should be documented. See C.7.2(30). 103/2
- Finalization of task attributes and reclamation of associated storage should be performed as soon as possible after task termination. See C.7.2(30.1/2). 104/2
- Names that end with "_Locking" should be used for implementation-defined locking policies. See D.3(17). 105/2
- Names that end with "_Queuing" should be used for implementation-defined queuing policies. See D.4(16). 106/2
- The abort_statement should not require the task executing the statement to block. See D.6(9). 107/2
- On a multi-processor, the delay associated with aborting a task on another processor should be bounded. See D.6(10). 108/2
- When feasible, specified restrictions should be used to produce a more efficient implementation. See D.7(21). 109/2
- When appropriate, mechanisms to change the value of Tick should be provided. See D.8(47). 110/2
- Calendar.Clock and Real_Time.Clock should be transformations of the same time base. See D.8(48). 111/2
- The "best" time base which exists in the underlying system should be available to the application through Real_Time.Clock. See D.8(49). 112/2
- On a multiprocessor system, each processor should have a separate and disjoint ready queue. See D.13(9). 112.1/3
- When appropriate, implementations should provide configuration mechanisms to change the value of Execution_Time.CPU_Tick. See D.14(29/2). 113/2
- For a timing event, the handler should be executed directly by the real-time clock interrupt mechanism. See D.15(25). 114/2

114.1/5 • Starting a protected action on a protected object statically assigned to a processor should not use busy-waiting. See D.16(16).

114.2/3 • Each dispatching domain should have separate and disjoint ready queues. See D.16.1(31).

115/2 • The PCS should allow for multiple tasks to call the RPC-receiver. See E.5(28).

116/2 • The System.RPC.Write operation should raise Storage_Error if it runs out of space when writing an item. See E.5(29).

117/2 • If COBOL (respectively, C) is supported in the target environment, then interfacing to COBOL (respectively, C) should be supported as specified in Annex B. See F(7/3).

118/2 • Packed decimal should be used as the internal representation for objects of subtype *S* when *S*'Machine_Radix = 10. See F.1(2).

119/2 • If Fortran (respectively, C) is supported in the target environment, then interfacing to Fortran (respectively, C) should be supported as specified in Annex B. See G(7/3).

120/2 • Mixed real and complex operations (as well as pure-imaginary and complex operations) should not be performed by converting the real (resp. pure-imaginary) operand to complex. See G.1.1(56/5).

121/3 • If Real'Signed_Zeros is True for Numerics.Generic_Complex_Types, a rational treatment of the signs of zero results and result components should be provided. See G.1.1(58).

122/3 • If Complex_Types.Real'Signed_Zeros is True for Numerics.Generic_Complex_Elementary_Functions, a rational treatment of the signs of zero results and result components should be provided. See G.1.2(49).

123/2 • For elementary functions, the forward trigonometric functions without a Cycle parameter should not be implemented by calling the corresponding version with a Cycle parameter. Log without a Base parameter should not be implemented by calling Log with a Base parameter. See G.2.4(19).

124/2 • For complex arithmetic, the Compose_From_Polar function without a Cycle parameter should not be implemented by calling Compose_From_Polar with a Cycle parameter. See G.2.6(15).

125/2 • Solve and Inverse for Numerics.Generic_Real_Arrays should be implemented using established techniques such as LU decomposition and the result should be refined by an iteration on the residuals. See G.3.1(88/3).

126/2 • The equality operator should be used to test that a matrix in Numerics.Generic_Real_Arrays is symmetric. See G.3.1(90/2).

126.1/3 • An implementation should minimize the circumstances under which the algorithm used for Numerics.Generic_Real_Arrays.Eigenvalues and Numerics.Generic_Real_Arrays.Eigensystem fails to converge. See G.3.1(91/3).

127/2 • Solve and Inverse for Numerics.Generic_Complex_Arrays should be implemented using established techniques and the result should be refined by an iteration on the residuals. See G.3.2(158/3).

128/2 • The equality and negation operators should be used to test that a matrix is Hermitian. See G.3.2(160/2).

128.1/3 • An implementation should minimize the circumstances under which the algorithm used for Numerics.Generic_Complex_Arrays.Eigenvalues and Numerics.Generic_Complex_Arrays.Eigensystem fails to converge. See G.3.2(160.1/3).

129/2 • Mixed real and complex operations should not be performed by converting the real operand to complex. See G.3.2(161/2).

130/2 • The information produced by pragma Reviewable should be provided in both a human-readable and machine-readable form, and the latter form should be documented. See H.3.1(19).

- Object code listings should be provided both in a symbolic format and in a numeric format. See H.3.1(20). 131/2
- If the partition elaboration policy is Sequential and the Environment task becomes permanently blocked during elaboration, then the partition should be immediately terminated. See H.6(15/3). 132/3
- When applied to a generic unit, a program unit pragma that is not a library unit pragma should apply to each instance of the generic unit for which there is not an overriding pragma applied directly to the instance. See J.15(9/5). 132.1/5

Annex N
(informative)
Glossary

This paragraph was deleted.{*AI95-00437-01*} {*AI12-0443-1*} 1/5

Informal definitions of various terms are now found in 1.3.

Annex P
(informative)
Syntax Summary

This Annex summarizes the complete syntax of the language.

P.1 Syntax Rules

{*AI12-0426-1*} This subclause lists the complete syntax of the language in the order it appears in this Reference Manual. See 1.1.4 for a description of the notation used. 1/5

2.3:
```
identifier ::=
   identifier_start {identifier_start | identifier_extend}
```

2.3:
```
identifier_start ::=
     letter_uppercase
   | letter_lowercase
   | letter_titlecase
   | letter_modifier
   | letter_other
   | number_letter
```

2.3:
```
identifier_extend ::=
     mark_non_spacing
   | mark_spacing_combining
   | number_decimal
   | punctuation_connector
```

2.4:
```
numeric_literal ::= decimal_literal | based_literal
```

2.4.1:
```
decimal_literal ::= numeral [.numeral] [exponent]
```

2.4.1:
```
numeral ::= digit {[underline] digit}
```

2.4.1:
```
exponent ::= E [+] numeral | E – numeral
```

2.4.1:
```
digit ::= 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9
```

2.4.2:
```
based_literal ::=
   base # based_numeral [.based_numeral] # [exponent]
```

2.4.2:
```
base ::= numeral
```

2.4.2:
```
based_numeral ::=
   extended_digit {[underline] extended_digit}
```

2.4.2:
```
extended_digit ::= digit | A | B | C | D | E | F
```

2.5:
```
character_literal ::= 'graphic_character'
```

2.6:
```
string_literal ::= "{string_element}"
```

2.6:

string_element ::= "" | *non_quotation_mark*_graphic_character

2.7:
comment ::= --{*non_end_of_line*_character}

2.8:
pragma ::=
  pragma identifier [(pragma_argument_association {, pragma_argument_association})];

2.8:
pragma_argument_association ::=
    [*pragma_argument*_identifier =>] name
  | [*pragma_argument*_identifier =>] expression
  | *pragma_argument*_aspect_mark => name
  | *pragma_argument*_aspect_mark => expression

3.1:
basic_declaration ::=
    type_declaration | subtype_declaration
  | object_declaration | number_declaration
  | subprogram_declaration | abstract_subprogram_declaration
  | null_procedure_declaration | expression_function_declaration
  | package_declaration | renaming_declaration
  | exception_declaration | generic_declaration
  | generic_instantiation

3.1:
defining_identifier ::= identifier

3.2.1:
type_declaration ::= full_type_declaration
  | incomplete_type_declaration
  | private_type_declaration
  | private_extension_declaration

3.2.1:
full_type_declaration ::=
    type defining_identifier [known_discriminant_part] **is** type_definition
      [aspect_specification];
  | task_type_declaration
  | protected_type_declaration

3.2.1:
type_definition ::=
    enumeration_type_definition | integer_type_definition
  | real_type_definition | array_type_definition
  | record_type_definition | access_type_definition
  | derived_type_definition | interface_type_definition

3.2.2:
subtype_declaration ::=
  subtype defining_identifier **is** subtype_indication
      [aspect_specification];

3.2.2:
subtype_indication ::= [null_exclusion] subtype_mark [constraint]

3.2.2:
subtype_mark ::= *subtype*_name

3.2.2:
constraint ::= scalar_constraint | composite_constraint

3.2.2:
scalar_constraint ::=
    range_constraint | digits_constraint | delta_constraint

3.2.2:
composite_constraint ::=
    index_constraint | discriminant_constraint

3.3.1:

object_declaration ::=
   defining_identifier_list : [**aliased**] [**constant**] subtype_indication [:= expression]
      [aspect_specification];
 | defining_identifier_list : [**aliased**] [**constant**] access_definition [:= expression]
      [aspect_specification];
 | defining_identifier_list : [**aliased**] [**constant**] array_type_definition [:= expression]
      [aspect_specification];
 | single_task_declaration
 | single_protected_declaration

3.3.1:
defining_identifier_list ::=
 defining_identifier {, defining_identifier}

3.3.2:
number_declaration ::=
    defining_identifier_list : **constant** := *static_*expression;

3.4:
derived_type_definition ::=
   [**abstract**] [**limited**] **new** *parent_*subtype_indication [[**and** interface_list] record_extension_part]

3.5:
range_constraint ::= **range** range

3.5:
range ::= range_attribute_reference
  | simple_expression .. simple_expression

3.5.1:
enumeration_type_definition ::=
  (enumeration_literal_specification {, enumeration_literal_specification})

3.5.1:
enumeration_literal_specification ::=
   defining_identifier | defining_character_literal

3.5.1:
defining_character_literal ::= character_literal

3.5.4:
integer_type_definition ::=
   signed_integer_type_definition | modular_type_definition

3.5.4:
signed_integer_type_definition ::=
   range *static_*simple_expression .. *static_*simple_expression

3.5.4:
modular_type_definition ::= **mod** *static_*expression

3.5.6:
real_type_definition ::=
   floating_point_definition | fixed_point_definition

3.5.7:
floating_point_definition ::=
   digits *static_*expression [real_range_specification]

3.5.7:
real_range_specification ::=
   range *static_*simple_expression .. *static_*simple_expression

3.5.9:
fixed_point_definition ::=
   ordinary_fixed_point_definition | decimal_fixed_point_definition

3.5.9:
ordinary_fixed_point_definition ::=
   delta *static_*expression real_range_specification

3.5.9:
decimal_fixed_point_definition ::=
   delta *static_*expression **digits** *static_*expression [real_range_specification]

3.5.9:
digits_constraint ::=
  digits *static*_simple_expression [range_constraint]

3.6:
array_type_definition ::=
  unconstrained_array_definition | constrained_array_definition

3.6:
unconstrained_array_definition ::=
  array(index_subtype_definition {, index_subtype_definition}) **of** component_definition

3.6:
index_subtype_definition ::= subtype_mark **range** <>

3.6:
constrained_array_definition ::=
  array (discrete_subtype_definition {, discrete_subtype_definition}) **of** component_definition

3.6:
discrete_subtype_definition ::= *discrete*_subtype_indication | range

3.6:
component_definition ::=
  [**aliased**] subtype_indication
| [**aliased**] access_definition

3.6.1:
index_constraint ::= (discrete_range {, discrete_range})

3.6.1:
discrete_range ::= *discrete*_subtype_indication | range

3.7:
discriminant_part ::= unknown_discriminant_part | known_discriminant_part

3.7:
unknown_discriminant_part ::= (<>)

3.7:
known_discriminant_part ::=
  (discriminant_specification {; discriminant_specification})

3.7:
discriminant_specification ::=
  defining_identifier_list : [null_exclusion] subtype_mark [:= default_expression]
    [aspect_specification]
| defining_identifier_list : access_definition [:= default_expression]
    [aspect_specification]

3.7:
default_expression ::= expression

3.7.1:
discriminant_constraint ::=
  (discriminant_association {, discriminant_association})

3.7.1:
discriminant_association ::=
  [*discriminant*_selector_name {'|' *discriminant*_selector_name} =>] expression

3.8:
record_type_definition ::= [[**abstract**] **tagged**] [**limited**] record_definition

3.8:
record_definition ::=
   record
     component_list
   end record [*record*_identifier]
 | **null record**

3.8:
component_list ::=
    component_item {component_item}

```
  | {component_item} variant_part
  | null;
```

3.8:
```
component_item ::= component_declaration | aspect_clause
```

3.8:
```
component_declaration ::=
  defining_identifier_list : component_definition [:= default_expression]
     [aspect_specification];
```

3.8.1:
```
variant_part ::=
  case discriminant_direct_name is
     variant
    {variant}
  end case;
```

3.8.1:
```
variant ::=
  when discrete_choice_list =>
    component_list
```

3.8.1:
```
discrete_choice_list ::= discrete_choice {'|' discrete_choice}
```

3.8.1:
```
discrete_choice ::=
  choice_expression | discrete_subtype_indication | range | others
```

3.9.1:
```
record_extension_part ::= with record_definition
```

3.9.3:
```
abstract_subprogram_declaration ::=
   [overriding_indicator]
   subprogram_specification is abstract
      [aspect_specification];
```

3.9.4:
```
interface_type_definition ::=
   [limited | task | protected | synchronized] interface [and interface_list]
```

3.9.4:
```
interface_list ::= interface_subtype_mark {and interface_subtype_mark}
```

3.10:
```
access_type_definition ::=
   [null_exclusion] access_to_object_definition
 | [null_exclusion] access_to_subprogram_definition
```

3.10:
```
access_to_object_definition ::=
   access [general_access_modifier] subtype_indication
```

3.10:
```
general_access_modifier ::= all | constant
```

3.10:
```
access_to_subprogram_definition ::=
   access [protected] procedure parameter_profile
 | access [protected] function  parameter_and_result_profile
```

3.10:
```
null_exclusion ::= not null
```

3.10:
```
access_definition ::=
   [null_exclusion] access [constant] subtype_mark
 | [null_exclusion] access [protected] procedure parameter_profile
 | [null_exclusion] access [protected] function parameter_and_result_profile
```

3.10.1:
```
incomplete_type_declaration ::=
```

type defining_identifier [discriminant_part] [**is tagged**];

3.11:
declarative_part ::= {declarative_item}

3.11:
declarative_item ::=
basic_declarative_item | body

3.11:
basic_declarative_item ::=
basic_declaration | aspect_clause | use_clause

3.11:
body ::= proper_body | body_stub

3.11:
proper_body ::=
subprogram_body | package_body | task_body | protected_body

4.1:
name ::=
direct_name | explicit_dereference
| indexed_component | slice
| selected_component | attribute_reference
| type_conversion | function_call
| character_literal | qualified_expression
| generalized_reference | generalized_indexing
| target_name

4.1:
direct_name ::= identifier | operator_symbol

4.1:
prefix ::= name | implicit_dereference

4.1:
explicit_dereference ::= name.**all**

4.1:
implicit_dereference ::= name

4.1.1:
indexed_component ::= prefix(expression {, expression})

4.1.2:
slice ::= prefix(discrete_range)

4.1.3:
selected_component ::= prefix . selector_name

4.1.3:
selector_name ::= identifier | character_literal | operator_symbol

4.1.4:
attribute_reference ::=
prefix'attribute_designator
| reduction_attribute_reference

4.1.4:
attribute_designator ::=
identifier[(*static*_expression)]
| Access | Delta | Digits | Mod

4.1.4:
range_attribute_reference ::= prefix'range_attribute_designator

4.1.4:
range_attribute_designator ::= Range[(*static*_expression)]

4.1.5:
generalized_reference ::= *reference_object*_name

4.1.6:
generalized_indexing ::= *indexable_container_object*_prefix actual_parameter_part

4.3:
aggregate ::=
   record_aggregate | extension_aggregate | array_aggregate
 | delta_aggregate | container_aggregate

4.3.1:
record_aggregate ::= (record_component_association_list)

4.3.1:
record_component_association_list ::=
   record_component_association {, record_component_association}
 | **null record**

4.3.1:
record_component_association ::=
   [component_choice_list =>] expression
 | component_choice_list => <>

4.3.1:
component_choice_list ::=
    *component*_selector_name {'|' *component*_selector_name}
 | **others**

4.3.2:
extension_aggregate ::=
   (ancestor_part **with** record_component_association_list)

4.3.2:
ancestor_part ::= expression | subtype_mark

4.3.3:
array_aggregate ::=
   positional_array_aggregate | null_array_aggregate | named_array_aggregate

4.3.3:
positional_array_aggregate ::=
   (expression, expression {, expression})
 | (expression {, expression}, **others** => expression)
 | (expression {, expression}, **others** => <>)
 | '[' expression {, expression}[, **others** => expression] ']'
 | '[' expression {, expression}, **others** => <> ']'

4.3.3:
null_array_aggregate ::= '[' ']'

4.3.3:
named_array_aggregate ::=
   (array_component_association_list)
 | '[' array_component_association_list ']'

4.3.3:
array_component_association_list ::=
   array_component_association {, array_component_association}

4.3.3:
array_component_association ::=
   discrete_choice_list => expression
 | discrete_choice_list => <>
 | iterated_component_association

4.3.3:
iterated_component_association ::=
   for defining_identifier **in** discrete_choice_list => expression
 | **for** iterator_specification => expression

4.3.4:
delta_aggregate ::= record_delta_aggregate | array_delta_aggregate

4.3.4:
record_delta_aggregate ::=
   (*base*_expression **with delta** record_component_association_list)

4.3.4:

array_delta_aggregate ::=
   (*base*_expression **with delta** array_component_association_list)
 | '[' *base*_expression **with delta** array_component_association_list ']'

4.3.5:
container_aggregate ::=
   null_container_aggregate
 | positional_container_aggregate
 | named_container_aggregate

4.3.5:
null_container_aggregate ::= '[' ']'

4.3.5:
positional_container_aggregate ::= '[' expression{, expression} ']'

4.3.5:
named_container_aggregate ::= '[' container_element_association_list ']'

4.3.5:
container_element_association_list ::=
   container_element_association {, container_element_association}

4.3.5:
container_element_association ::=
   key_choice_list => expression
 | key_choice_list => <>
 | iterated_element_association

4.3.5:
key_choice_list ::= key_choice {'|' key_choice}

4.3.5:
key_choice ::= *key*_expression | discrete_range

4.3.5:
iterated_element_association ::=
   for loop_parameter_specification[**use** *key*_expression] => expression
 | **for** iterator_specification[**use** *key*_expression] => expression

4.4:
expression ::=
    relation {**and** relation} | relation {**and then** relation}
  | relation {**or** relation} | relation {**or else** relation}
  | relation {**xor** relation}

4.4:
choice_expression ::=
    choice_relation {**and** choice_relation}
  | choice_relation {**or** choice_relation}
  | choice_relation {**xor** choice_relation}
  | choice_relation {**and then** choice_relation}
  | choice_relation {**or else** choice_relation}

4.4:
choice_relation ::=
    simple_expression [relational_operator simple_expression]

4.4:
relation ::=
    simple_expression [relational_operator simple_expression]
  | *tested*_simple_expression [**not**] **in** membership_choice_list
  | raise_expression

4.4:
membership_choice_list ::= membership_choice {'|' membership_choice}

4.4:
membership_choice ::= *choice*_simple_expression | range | subtype_mark

4.4:
simple_expression ::=
   [unary_adding_operator] term {binary_adding_operator term}

4.4:
term ::= factor {multiplying_operator factor}

4.4:
factor ::= primary [** primary] | **abs** primary | **not** primary

4.4:
primary ::=
   numeric_literal | **null** | string_literal | aggregate
 | name | allocator | (expression)
 | (conditional_expression) | (quantified_expression)
 | (declare_expression)

4.5:
logical_operator ::= **and** | **or** | **xor**

4.5:
relational_operator ::= = | /= | < | <= | > | >=

4.5:
binary_adding_operator ::= + | – | &

4.5:
unary_adding_operator ::= + | –

4.5:
multiplying_operator ::= * | / | **mod** | **rem**

4.5:
highest_precedence_operator ::= ** | **abs** | **not**

4.5.7:
conditional_expression ::= if_expression | case_expression

4.5.7:
if_expression ::=
  if condition **then** *dependent_*expression
  {**elsif** condition **then** *dependent_*expression}
  [**else** *dependent_*expression]

4.5.7:
condition ::= *boolean_*expression

4.5.7:
case_expression ::=
   case *selecting_*expression **is**
   case_expression_alternative {,
   case_expression_alternative}

4.5.7:
case_expression_alternative ::=
   when discrete_choice_list =>
      *dependent_*expression

4.5.8:
quantified_expression ::=
   for quantifier loop_parameter_specification => predicate
 | **for** quantifier iterator_specification => predicate

4.5.8:
quantifier ::= **all** | **some**

4.5.8:
predicate ::= *boolean_*expression

4.5.9:
declare_expression ::=
   declare {declare_item}
   begin *body_*expression

4.5.9:
declare_item ::= object_declaration | object_renaming_declaration

4.5.10:
reduction_attribute_reference ::=

value_sequence'reduction_attribute_designator
| prefix'reduction_attribute_designator

4.5.10:
value_sequence ::=
'[' [**parallel**[(chunk_specification)] [aspect_specification]]
iterated_element_association ']'

4.5.10:
reduction_attribute_designator ::=
*reduction_*identifier(reduction_specification)

4.5.10:
reduction_specification ::= *reducer_*name, *initial_value_*expression

4.6:
type_conversion ::=
subtype_mark(expression)
| subtype_mark(name)

4.7:
qualified_expression ::=
subtype_mark'(expression) | subtype_mark'aggregate

4.8:
allocator ::=
new [subpool_specification] subtype_indication
| **new** [subpool_specification] qualified_expression

4.8:
subpool_specification ::= (*subpool_handle_*name)

5.1:
sequence_of_statements ::= statement {statement} {label}

5.1:
statement ::=
{label} simple_statement | {label} compound_statement

5.1:
simple_statement ::= null_statement
| assignment_statement | exit_statement
| goto_statement | procedure_call_statement
| simple_return_statement | entry_call_statement
| requeue_statement | delay_statement
| abort_statement | raise_statement
| code_statement

5.1:
compound_statement ::=
if_statement | case_statement
| loop_statement | block_statement
| extended_return_statement
| parallel_block_statement
| accept_statement | select_statement

5.1:
null_statement ::= **null**;

5.1:

Annex Q
(informative)
Language-Defined Entities

{*AI95-00440-01*} This annex lists the language-defined entities of the language. A list of language-defined library units can be found in Annex A, "Predefined Language Environment". 1/2

Q.1 Language-Defined Packages

{*AI95-00440-01*} {*AI05-0299-1*} This subclause lists all language-defined packages. 1/3

Q.2 Language-Defined Types and Subtypes

1/3 {*AI95-00440-01*} {*AI05-0299-1*} This subclause lists all language-defined types and subtypes.

Address
  in System 13.7(12)
Alignment
  in Ada.Strings A.4.1(6)
Alphanumeric
  in Interfaces.COBOL B.4(16/3)
Any_Priority *subtype of* Integer
  in System 13.7(16)
Attribute_Handle
  in Ada.Task_Attributes C.7.2(3)
Barrier_Limit *subtype of* Positive
  in Ada.Synchronous_Barriers D.10.1(4/3)
Big_Integer
  in Ada.Numerics.Big_Numbers.Big_Integers A.5.6(3/5)
Big_Natural *subtype of* Big_Integer
  in Ada.Numerics.Big_Numbers.Big_Integers A.5.6(9/5)
Big_Positive *subtype of* Big_Integer
  in Ada.Numerics.Big_Numbers.Big_Integers A.5.6(8/5)
Big_Real
  in Ada.Numerics.Big_Numbers.Big_Reals A.5.7(3/5)
Binary
  in Interfaces.COBOL B.4(10)
Binary_Format
  in Interfaces.COBOL B.4(24)
Bit_Order
  in System 13.7(15/2)
Boolean
  in Standard A.1(5)
Bounded_String
  in Ada.Strings.Bounded A.4.4(6)
Buffer_Type
  in Ada.Strings.Text_Buffers.Bounded A.4.12(27/5)
  in Ada.Strings.Text_Buffers.Unbounded A.4.12(19/5)
Buffer_Type *subtype of* Storage_Array
  in Ada.Storage_IO A.9(4)
Byte
  in Interfaces.COBOL B.4(29/3)

Byte_Array
in Interfaces.COBOL B.4(29/3)
C_bool

Q.5 Language-Defined Objects

1/3 {*AI95-00440-01*} {*AI05-0299-1*} This subclause lists all language-defined constants, variables, named numbers, and enumeration literals.

1.a/2 **To be honest:** Formally, named numbers and enumeration literals aren't objects, but it was thought to be too weird to say “Language-Defined Objects and Values”.
