
  Ramification: Evaluating the entry_index of an accept_statement is not synchronized with a corresponding entry call, nor is evaluating the entry barrier of an entry_body. 7.a
- If A1 is part of the execution of an accept_statement or entry_body, and A2 is the action of returning from the corresponding entry call; 8
- If A1 is part of the execution of a protected procedure body or entry_body for a given protected object, and A2 is part of a later execution of an entry_body for the same protected object; 9

  Reason: The underlying principle here is that for one action to “signal” a second, the second action has to follow a potentially blocking operation, whose blocking is dependent on the first action in some way. Protected procedures are not potentially blocking, so they can only be "signalers", they cannot be signaled. 9.a

  Ramification: Protected subprogram calls are not defined to signal one another, which means that such calls alone cannot be used to synchronize access to shared data outside of a protected object. 9.b

  Reason: The point of this distinction is so that on multiprocessors with inconsistent caches, the caches only need to be refreshed at the beginning of an entry body, and forced out at the end of an entry body or protected procedure that leaves an entry open. Protected function calls, and protected subprogram calls for entryless protected objects do not require full cache consistency. Entryless protected objects are intended to be treated roughly like atomic objects — each operation is indivisible with respect to other operations (unless both are reads), but such operations cannot be used to synchronize access to other nonvolatile shared variables. 9.c
- If A1 signals some action that in turn signals A2. 10

{*AI12-0298-1*} Action A1 is defined to *potentially signal* action A2 if A1 signals A2, if action A1 and A2 occur as part of the execution of the same logical thread of control, and the language rules permit action A1 to precede action A2, or if action A1 potentially signals some action that in turn potentially signals A2. 10.1/5

{*AI12-0267-1*} Two actions are defined to be *sequential* if one of the following is true: 11/5

- One action signals the other; 12
- {*AI12-0119-1*} Both actions occur as part of the execution of the same logical thread of control; 13/5

13.a/5 **Reason:** {*AI12-0005-1*} {*AI12-0119-1*} Any two actions of the same logical thread of control are sequential, even if one does not signal the other because they can be executed in an "arbitrary" (but necessarily equivalent to some "sequential") order.

14/5 - {*AI12-0292-1*} Both actions occur as part of protected actions on the same protected object, and at least one of the actions is part of a call on an exclusive protected operation of the protected object.

14.a/5 **Reason:** {*AI12-0292-1*} Because actions within protected actions do not always imply signaling, we have to mention them here explicitly to make sure that actions occurring within different protected actions of the same protected object are sequential with respect to one another (unless both are part of calls on nonexclusive protected functions).

14.b/5 **Ramification:** {*AI12-0292-1*} It doesn't matter whether or not the variable being assigned is actually a subcomponent of the protected object; globals can be safely updated from within the bodies of protected procedures, protected entries, or exclusive protected functions.

15/3 {*AI05-0229-1*} Aspect Atomic or aspect Atomic_Components may also be specified to ensure that certain reads and updates are sequential — see C.6.

15.a/5 **Ramification:** {*AI12-0119-1*} If two actions are "sequential" it is known that their executions don't overlap in time, but it is not necessarily specified which occurs first. For example, all actions of a single logical thread of control are sequential, even though the exact order of execution is not fully specified for all constructs.

15.b **Discussion:** Note that if two assignments to the same variable are sequential, but neither signals the other, then the program is not erroneous, but it is not specified which assignment ultimately prevails. Such a situation usually corresponds to a programming mistake, but in some (rare) cases, the order makes no difference, and for this reason this situation is not considered erroneous nor even a bounded error. In Ada 83, this was considered an "incorrect order dependence" if the "effect" of the program was affected, but "effect" was never fully defined. In Ada 95, this situation represents a potential nonportability, and a friendly compiler might want to warn the programmer about the situation, but it is not considered an error. An example where this would come up would be in gathering statistics as part of referencing some information, where the assignments associated with statistics gathering don't need to be ordered since they are just accumulating aggregate counts, sums, products, etc.

16/5 {*AI12-0267-1*} Two actions that are not sequential are defined to be *concurrent* actions.

17/5 {*AI12-0267-1*} {*AI12-0298-1*} Two actions are defined to *conflict* if one action assigns to an object, and the other action reads or assigns to a part of the same object (or of a neighboring object if the two are not independently addressable). The action comprising a call on a subprogram or an entry is defined to *potentially conflict* with another action if the Global aspect (or Global'Class aspect in the case of a dispatching call) of the called subprogram or entry is such that a conflicting action would be possible during the execution of the call. Similarly, two calls are considered to potentially conflict if they each have Global (or Global'Class in the case of a dispatching call) aspects such that conflicting actions would be possible during the execution of the calls. Finally, two actions that conflict are also considered to potentially conflict.

18/5 {*AI12-0267-1*} A *synchronized* object is an object of a task or protected type, an atomic object (see C.6), a suspension object (see D.10), or a synchronous barrier (see D.10.1). [Operations on such objects are necessarily sequential with respect to one another, and hence are never considered to conflict.]

Erroneous Execution

19/5 {*AI12-0267-1*} The execution of two concurrent actions is erroneous if the actions make conflicting uses of a shared variable (or neighboring variables that are not independently addressable).

Wording Changes from Ada 95

19.a/2 {*8652/0031*} {*AI95-00118-01*} **Corrigendum:** Clarified that a task T2 can rely on values of variables that are updated by another task T1, if task T2 first verifies that T1'Terminated is True.

Wording Changes from Ada 2005

19.b/3 {*AI05-0009-1*} {*AI05-0201-1*} **Correction:** Revised the definition of independent addressability to exclude conforming representation clauses and to require that atomic and independent objects always have independent addressability. This should not change behavior that the user sees for any Ada program, so it is not an inconsistency.

{*AI05-0072-1*} **Correction:** Corrected the wording of AI95-00118-01 to actually say what was intended (as described above). 19.c/3

Wording Changes from Ada 2012

{*AI12-0119-1*} Added wording to support interaction of parallel constructs with tasks by changing various wording to talk about logical threads of control rather than purely about tasks. 19.d/5

{*AI12-0267-1*} {*AI12-0298-1*} Added wording to define potentially signalling actions and conflicting actions; these are used to define conflict policies. 19.e/5

9.10.1 Conflict Check Policies

{*AI12-0267-1*} This subclause determines what checks are performed relating to possible concurrent conflicting actions (see 9.10). 1/5

Syntax

{*AI12-0267-1*} {*AI12-0298-1*} The form of a pragma Conflict_Check_Policy is as follows: 2/5

pragma Conflict_Check_Policy (*policy_*identifier[, *policy_*identifier]); 3/5

{*AI12-0267-1*} A pragma Conflict_Check_Policy is allowed only immediately within a declarative_part, a package_specification, or as a configuration pragma. 4/5

Legality Rules

{*AI12-0267-1*} Each *policy_*identifier shall be one of No_Parallel_Conflict_Checks, Known_Parallel_Conflict_Checks, All_Parallel_Conflict_Checks, No_Tasking_Conflict_Checks, Known_Tasking_Conflict_Checks, All_Tasking_Conflict_Checks, No_Conflict_Checks, Known_Conflict_Checks, All_Conflict_Checks, or an implementation-defined conflict check policy. If two *policy_*identifiers are given, one shall include the word Parallel and one shall include the word Tasking. If only one *policy_*identifier is given, it shall not include the word Parallel or Tasking. 5/5

Implementation defined: Implementation-defined conflict check policies. 5.a.1/5

{*AI12-0267-1*} A pragma Conflict_Check_Policy given in a declarative_part or immediately within a package_specification applies from the place of the pragma to the end of the innermost enclosing declarative region. The region for a pragma Conflict_Check_Policy given as a configuration pragma is the declarative region for the entire compilation unit (or units) to which it applies. 6/5

{*AI12-0267-1*} If a pragma Conflict_Check_Policy applies to a generic_instantiation, then the pragma Conflict_Check_Policy applies to the entire instance. 7/5

{*AI12-0267-1*} {*AI12-0294-1*} {*AI12-0298-1*} If multiple Conflict_Check_Policy pragmas apply to a given construct, the conflict check policy is determined by the one in the innermost enclosing region. If no Conflict_Check_Policy pragma applies to a construct, the policy is (All_Parallel_Conflict_Checks, No_Tasking_Conflict_Checks) (see below). 8/5

To be honest: {*AI12-0294-1*} The region mentioned in this rule is the region to which the policy pragma applies, and not the declarative region in which the policy pragma appears. This distinction matters when there are multiple policy pragmas in a single declarative region. 8.a/5

{*AI12-0267-1*} {*AI12-0298-1*} Certain potentially conflicting actions are disallowed according to which conflict check policies apply at the place where the action or actions occur, as follows: 9/5

No_Parallel_Conflict_Checks 10/5

This policy imposes no restrictions on concurrent actions arising from parallel constructs.

No_Tasking_Conflict_Checks 11/5

This policy imposes no restrictions on concurrent actions arising from tasking constructs.

12/5 Known_Parallel_Conflict_Checks

If this policy applies to two concurrent actions appearing within parallel constructs, they are disallowed if they are known to denote the same object (see 6.4.1) with uses that conflict. For the purposes of this check, any parallel loop may be presumed to involve multiple concurrent iterations. Also, for the purposes of deciding whether two actions are concurrent, it is enough for the logical threads of control in which they occur to be concurrent at any point in their execution, unless all of the following are true:

13/5 • the shared object is volatile;

14/5 • the two logical threads of control are both known to also refer to a shared synchronized object; and

15/5 • each thread whose potentially conflicting action updates the shared volatile object, also updates this shared synchronized object.

15.a/5 **Reason:** To properly synchronize two actions to prevent concurrency, a thread that does an update of a volatile object must update a synchronized object afterwards to indicate it has completed its update, and the other thread needs to test the value of the synchronized object before it reads the updated volatile object. In a parallel construct, "signaling" cannot be used to prevent concurrency, since that generally requires some blocking, so testing the value of the synchronized object would probably need to use a busy-wait loop.

16/5 Known_Tasking_Conflict_Checks

If this policy applies to two concurrent actions appearing within the same compilation unit, at least one of which appears within a task body but not within a parallel construct, they are disallowed if they are known to denote the same object (see 6.4.1) with uses that conflict, and neither potentially signals the other (see 9.10). For the purposes of this check, any named task type may be presumed to have multiple instances. Also, for the purposes of deciding whether two actions are concurrent, it is enough for the tasks in which they occur to be concurrent at any point in their execution, unless all of the following are true:

17/5 • the shared object is volatile;

18/5 • the two tasks are both known to also refer to a shared synchronized object; and

19/5 • each task whose potentially conflicting action updates the shared volatile object, also updates this shared synchronized object.

19.a/5 **Reason:** To properly synchronize two actions to prevent concurrency, a task that does an update of a *non*volatile object must use signaling via a synchronized object to indicate it has completed its update, and the other task needs to be signaled by this action on the synchronized object before it reads the updated nonvolatile object. In other words, to synchronize communication via a nonvolatile object, signaling must be used. To synchronize communication via a volatile object, an update of a shared synchronized object followed by a read of the synchronized object in the other task can be sufficient.

20/5 All_Parallel_Conflict_Checks

This policy includes the restrictions imposed by the Known_Parallel_Conflict_Checks policy, and in addition disallows a parallel construct from reading or updating a variable that is global to the construct, unless it is a synchronized object, or unless the construct is a parallel loop, and the global variable is a part of a component of an array denoted by an indexed component with at least one index expression that statically denotes the loop parameter of the loop_parameter_specification or the chunk parameter of the parallel loop.

21/5 All_Tasking_Conflict_Checks

This policy includes the restrictions imposed by the Known_Tasking_Conflict_Checks policy, and in addition disallows a task body from reading or updating a variable that is global to the task body, unless it is a synchronized object.

22/5 No_Conflict_Checks, Known_Conflict_Checks, All_Conflict_Checks

These are shorthands for (No_Parallel_Conflict_Checks, No_Tasking_Conflict_Checks), (Known_Parallel_Conflict_Checks, Known_Tasking_Conflict_Checks), and (All_Parallel_Conflict_Checks, All_Tasking_Conflict_Checks), respectively.

Static Semantics

{*AI12-0344-1*} For a subprogram, the following language-defined representation aspect may be specified: 23/5

Parallel_Calls 24/5

The Parallel_Calls aspect is of type Boolean. The specified value shall be static. The Parallel_Calls aspect of an inherited primitive subprogram is True if Parallel_Calls is True either for the corresponding subprogram of the progenitor type or for any other inherited subprogram that it overrides. If not specified or inherited as True, the Parallel_Calls aspect of a subprogram is False.

Specifying the Parallel_Calls aspect to be True for a subprogram indicates that the subprogram can be safely called in parallel. Conflict checks (if required by the Conflict_Check_Policy in effect) are made on the subprogram assuming that multiple concurrent calls exist.[Such checks can then be omitted on a call of the subprogram in a parallel iteration context.] 25/5

Aspect Description for Parallel_Calls: Specifies whether a given subprogram is expected to be called in parallel. 25.a/5

Implementation Permissions

{*AI12-0267-1*} {*AI12-0298-1*} When the conflict check policy Known_Parallel_Conflict_Checks or All_Parallel_Conflict_Checks applies, the implementation may disallow two concurrent actions appearing within parallel constructs if the implementation can prove they will at run-time denote the same object with uses that conflict. Similarly, when the conflict check policy Known_Tasking_Conflict_Checks or All_Tasking_Conflict_Checks applies, the implementation may disallow two concurrent actions, at least one of which appears within a task body but not within a parallel construct, if the implementation can prove they will at run-time denote the same object with uses that conflict. 26/5

Ramification: This permission allows additional enforcement in instance bodies (where Legality Rules aren't usually enforced), in subunits and their parents, and across compilation units, if the implementation wishes. 26.a/5

Extensions to Ada 2012

{*AI12-0267-1*} Conflict check policies (and the associated checks) are new. 26.b/5

{*AI12-0344-1*} Aspect Parallel_Calls is new. 26.c/5

9.11 Example of Tasking and Synchronization

Examples

{*AI12-0440-1*} The following example defines a buffer protected object to smooth variations between the speed of output of a producing task and the speed of input of some consuming task. For instance, the producing task can have the following structure: 1/5

```
task Producer;                                                    2
{AI95-00433-01} task body Producer is                             3/2
   Person : Person_Name; -- see 3.10.1
begin
   loop
      ... -- simulate arrival of the next customer
      Buffer.Append_Wait(Person);
      exit when Person = null;
   end loop;
end Producer;
```

{*AI12-0440-1*} and the consuming task can have the following structure: 4/5

```
task Consumer;                                                    5
```

6/2
```
{AI95-00433-01} task body Consumer is
   Person : Person_Name;
begin
   loop
      Buffer.Remove_First_Wait(Person);
      exit when Person = null;
      ... -- simulate serving a customer
   end loop;
end Consumer;
```

7/2 {*AI95-00433-01*} The buffer object contains an internal array of person names managed in a round-robin fashion. The array has two indices, an In_Index denoting the index for the next input person name and an Out_Index denoting the index for the next output person name.

7.1/2 {*AI95-00433-01*} The Buffer is defined as an extension of the Synchronized_Queue interface (see 3.9.4), and as such promises to implement the abstraction defined by that interface. By doing so, the Buffer can be passed to the Transfer class-wide operation defined for objects of a type covered by Queue'Class.

7.2/5
```
{AI12-0178-1} type Person_Name_Array is array (Positive range <>)
   of Person_Name;  -- see 3.10.1
```

8/2
```
{AI95-00433-01} protected Buffer is new Synchronized_Queue with  -- see 3.9.4
   entry Append_Wait(Person : in Person_Name);
   entry Remove_First_Wait(Person : out Person_Name);
   function Cur_Count return Natural;
   function Max_Count return Natural;
   procedure Append(Person : in Person_Name);
   procedure Remove_First(Person : out Person_Name);
private
   Pool      : Person_Name_Array(1 .. 100);
   Count     : Natural := 0;
   In_Index, Out_Index : Positive := 1;
end Buffer;
```

9/2
```
{AI95-00433-01} protected body Buffer is
   entry Append_Wait(Person : in Person_Name)
      when Count < Pool'Length is
   begin
      Append(Person);
   end Append_Wait;
```

9.1/2
```
{AI95-00433-01}    procedure Append(Person : in Person_Name) is
   begin
      if Count = Pool'Length then
         raise Queue_Error with "Buffer Full";  -- see 11.3
      end if;
      Pool(In_Index) := Person;
      In_Index       := (In_Index mod Pool'Length) + 1;
      Count          := Count + 1;
   end Append;
```

10/2
```
{AI95-00433-01}    entry Remove_First_Wait(Person : out Person_Name)
      when Count > 0 is
   begin
      Remove_First(Person);
   end Remove_First_Wait;
```

11/2
```
{AI95-00433-01}    procedure Remove_First(Person : out Person_Name) is
   begin
      if Count = 0 then
         raise Queue_Error with "Buffer Empty"; -- see 11.3
      end if;
      Person    := Pool(Out_Index);
      Out_Index := (Out_Index mod Pool'Length) + 1;
      Count     := Count - 1;
   end Remove_First;
```

```
{AI95-00433-01}    function Cur_Count return Natural is                    12/2
   begin
       return Buffer.Count;
   end Cur_Count;
{AI95-00433-01}    function Max_Count return Natural is                    13/2
   begin
       return Pool'Length;
   end Max_Count;
end Buffer;
```

10 Program Structure and Compilation Issues

{*AI05-0299-1*} [The overall structure of programs and the facilities for separate compilation are described in this clause. A *program* is a set of *partitions*, each of which may execute in a separate address space, possibly on a separate computer. 1/3

Term entry: program — set of partitions, each of which can execute in a separate address space, possibly on a separate computer 1.a/5

Term entry: partition — part of a program, which consists of a set of interdependent library units 1.b/5
Note: Each partition can run in a separate address space, possibly on a separate computer. A program can contain just one partition, or it can be distributed across multiple partitions, which can execute concurrently.

As explained below, a partition is constructed from *library units*. Syntactically, the declaration of a library unit is a library_item, as is the body of a library unit. An implementation may support a concept of a *program library* (or simply, a "library"), which contains library_items and their subunits. Library units may be organized into a hierarchy of children, grandchildren, and so on.] 2

{*AI05-0299-1*} This clause has two subclauses: 10.1, "Separate Compilation" discusses compile-time issues related to separate compilation. 10.2, "Program Execution" discusses issues related to what is traditionally known as "link time" and "run time" — building and executing partitions. 3/3

Language Design Principles

We should avoid specifying details that are outside the domain of the language itself. The standard is intended (at least in part) to promote portability of Ada programs at the source level. It is not intended to standardize extra-language issues such as how one invokes the compiler (or other tools), how one's source is represented and organized, version management, the format of error messages, etc. 3.a

The rules of the language should be enforced even in the presence of separate compilation. Using separate compilation should not make a program less safe. 3.b

It should be possible to determine the legality of a compilation unit by looking only at the compilation unit itself and the compilation units upon which it depends semantically. As an example, it should be possible to analyze the legality of two compilation units in parallel if they do not depend semantically upon each other. 3.c

On the other hand, it may be necessary to look outside that set in order to generate code — this is generally true for generic instantiation and inlining, for example. Also on the other hand, it is generally necessary to look outside that set in order to check Post-Compilation Rules. 3.d

See also the "generic contract model" Language Design Principle of 12.3, "Generic Instantiation". 3.e

Wording Changes from Ada 83

{*AI05-0299-1*} The clause organization mentioned above is different from that of RM83. 3.f/3

10.1 Separate Compilation

[A *program unit* is either a package, a task unit, a protected unit, a protected entry, a generic unit, or an explicitly declared subprogram other than an enumeration literal. Certain kinds of program units can be separately compiled. Alternatively, they can appear physically nested within other program units. 1

Term entry: program unit — language construct that is a package, a task unit, a protected unit, a protected entry, a generic unit, or an explicitly declared subprogram other than an enumeration literal 1.a/5
Note: Certain kinds of program units can be separately compiled. Alternatively, they can appear physically nested within other program units.

The text of a program can be submitted to the compiler in one or more compilations. Each compilation is a succession of compilation_units. A compilation_unit contains either the declaration, the body, or a renaming of a program unit.] The representation for a compilation is implementation-defined. 2

Implementation defined: The representation for a compilation. 2.a

2.b **Ramification:** Some implementations might choose to make a compilation be a source (text) file. Others might allow multiple source files to be automatically concatenated to form a single compilation. Others still may represent the source in a nontextual form such as a parse tree. Note that the RM95 does not even define the concept of a source file.

2.c Note that a protected subprogram is a subprogram, and therefore a program unit. An instance of a generic unit is a program unit.

2.d A protected entry is a program unit, but protected entries cannot be separately compiled.

2.e/5 **Term entry: compilation unit** — program unit that is separately compiled
Note: A compilation_unit contains either the declaration, the body, or a renaming of a program unit.

3 A library unit is a separately compiled program unit, and is a package, subprogram, or generic unit. Library units may have other (logically nested) library units as children, and may have other program units physically nested within them. A root library unit, together with its children and grandchildren and so on, form a *subsystem*.

3.a/5 **Term entry: library unit** — separately compiled program unit, which is a package, a subprogram, or a generic unit
Note: Library units can have other (logically nested) library units as children, and can have other program units physically nested within them. A root library unit, together with its children and grandchildren and so on, form a subsystem.

Implementation Permissions

4 An implementation may impose implementation-defined restrictions on compilations that contain multiple compilation_units.

4.a **Implementation defined:** Any restrictions on compilations that contain multiple compilation_units.

4.b **Discussion:** For example, an implementation might disallow a compilation that contains two versions of the same compilation unit, or that contains the declarations for library packages P1 and P2, where P1 precedes P2 in the compilation but P1 has a with_clause that mentions P2.

Wording Changes from Ada 83

4.c The interactions between language issues and environmental issues are left open in Ada 95. The environment concept is new. In Ada 83, the concept of the program library, for example, appeared to be quite concrete, although the rules had no force, since implementations could get around them simply by defining various mappings from the concept of an Ada program library to whatever data structures were actually stored in support of separate compilation. Indeed, implementations were encouraged to do so.

4.d In RM83, it was unclear which was the official definition of "program unit". Definitions appeared in RM83-5, 6, 7, and 9, but not 12. Placing it here seems logical, since a program unit is sort of a potential compilation unit.

10.1.1 Compilation Units - Library Units

1 [A library_item is a compilation unit that is the declaration, body, or renaming of a library unit. Each library unit (except Standard) has a *parent unit*, which is a library package or generic library package.] A library unit is a *child* of its parent unit. The *root* library units are the children of the predefined library package Standard.

1.a **Ramification:** Standard is a library unit.

Syntax

2 compilation ::= {compilation_unit}

3 compilation_unit ::=
    context_clause library_item
  | context_clause subunit

4 library_item ::= [**private**] library_unit_declaration
  | library_unit_body
  | [**private**] library_unit_renaming_declaration

library_unit_declaration ::= 5
    subprogram_declaration | package_declaration
  | generic_declaration | generic_instantiation

library_unit_renaming_declaration ::= 6
  package_renaming_declaration
| generic_renaming_declaration
| subprogram_renaming_declaration

library_unit_body ::= subprogram_body | package_body 7

parent_unit_name ::= name 8

{*AI95-00397-01*} An overriding_indicator is not allowed in a subprogram_declaration, generic_instantiation, or subprogram_renaming_declaration that declares a library unit. 8.1/2

Reason: All of the listed items syntactically include overriding_indicator, but a library unit can never override anything. A majority of the ARG thought that allowing **not overriding** in that case would be confusing instead of helpful. 8.a.1/2

A *library unit* is a program unit that is declared by a library_item. When a program unit is a library unit, the prefix "library" is used to refer to it (or "generic library" if generic), as well as to its declaration and body, as in "library procedure", "library package_body", or "generic library package". The term *compilation unit* is used to refer to a compilation_unit. When the meaning is clear from context, the term is also used to refer to the library_item of a compilation_unit or to the proper_body of a subunit [(that is, the compilation_unit without the context_clause and the **separate** (parent_unit_name))]. 9

Discussion: In this example: 9.a

```
with Ada.Text_IO;                                                    9.b
package P is
   ...
end P;
```

the term "compilation unit" can refer to this text: "**with** Ada.Text_IO; **package** P **is** ... **end** P;" or to this text: "**package** P **is** ... **end** P;". We use this shorthand because it corresponds to common usage. 9.c

We like to use the word "unit" for declaration-plus-body things, and "item" for declaration or body separately (as in declarative_item). The terms "compilation_unit", "compilation unit", and "subunit" are exceptions to this rule. We considered changing "compilation_unit", "compilation unit" to "compilation_item", "compilation item", respectively, but we decided not to. 9.d

The *parent declaration* of a library_item (and of the library unit) is the declaration denoted by the parent_unit_name, if any, of the defining_program_unit_name of the library_item. If there is no parent_unit_name, the parent declaration is the declaration of Standard, the library_item is a *root* library_item, and the library unit (renaming) is a *root* library unit (renaming). The declaration and body of Standard itself have no parent declaration. The *parent unit* of a library_item or library unit is the library unit declared by its parent declaration. 10

Discussion: The declaration and body of Standard are presumed to exist from the beginning of time, as it were. There is no way to actually write them, since there is no syntactic way to indicate lack of a parent. An attempt to compile a package Standard would result in Standard.Standard. 10.a

Reason: Library units (other than Standard) have "parent declarations" and "parent units". Subunits have "parent bodies". We didn't bother to define the other possibilities: parent body of a library unit, parent declaration of a subunit, parent unit of a subunit. These are not needed, and might get in the way of a correct definition of "child". 10.b

[The children of a library unit occur immediately within the declarative region of the declaration of the library unit.] The *ancestors* of a library unit are itself, its parent, its parent's parent, and so on. [(Standard is an ancestor of every library unit.)] The *descendant* relation is the inverse of the ancestor relation. 11

Reason: These definitions are worded carefully to avoid defining subunits as children. Only library units can be children. 11.a

We use the unadorned term "ancestors" here to concisely define both "ancestor unit" and "ancestor declaration". 11.b

12 A library_unit_declaration or a library_unit_renaming_declaration is *private* if the declaration is immediately preceded by the reserved word **private**; it is otherwise *public*. A library unit is private or public according to its declaration. The *public descendants* of a library unit are the library unit itself, and the public descendants of its public children. Its other descendants are *private descendants*.

12.a **Discussion:** The first concept defined here is that a library_item is either public or private (not in relation to anything else — it's just a property of the library unit). The second concept is that a library_item is a public descendant or private descendant *of a given ancestor*. A given library_item can be a public descendant of one of its ancestors, but a private descendant of some other ancestor.

12.b A subprogram declared by a subprogram_body (as opposed to a subprogram_declaration) is always public, since the syntax rules disallow the reserved word **private** on a body.

12.c Note that a private library unit is a *public* descendant of itself, but a *private* descendant of its parent. This is because it is visible outside itself — its privateness means that it is not visible outside its parent.

12.d Private children of Standard are legal, and follow the normal rules. It is intended that implementations might have some method for taking an existing environment, and treating it as a package to be "imported" into another environment, treating children of Standard in the imported environment as children of the imported package.

12.e **Ramification:** Suppose we have a public library unit A, a private library unit A.B, and a public library unit A.B.C. A.B.C is a public descendant of itself and of A.B, but a private descendant of A; since A.B is private to A, we don't allow A.B.C to escape outside A either. This is similar to the situation that would occur with physical nesting, like this:

12.f
```
package A is
private
    package B is
        package C is
        end C;
    private
    end B;
end A;
```

12.g Here, A.B.C is visible outside itself and outside A.B, but not outside A. (Note that this example is intended to illustrate the visibility of program units from the outside; the visibility within child units is not quite identical to that of physically nested units, since child units are nested after their parent's declaration.)

12.1/2 {*AI95-00217-06*} For each library package_declaration in the environment, there is an implicit declaration of a *limited view* of that library package. The limited view of a package contains:

12.2/3 - {*AI95-00217-06*} {*AI05-0129-1*} {*AI05-0262-1*} For each package_declaration occurring immediately within the visible part, a declaration of the limited view of that package, with the same defining_program_unit_name.

12.3/3 - {*AI95-00217-06*} {*AI95-00326-01*} {*AI05-0108-1*} {*AI05-0129-1*} {*AI05-0262-1*} For each type_declaration occurring immediately within the visible part that is not an incomplete_type_declaration, an incomplete view of the type with no discriminant_part; if the type_declaration is tagged, then the view is a tagged incomplete view.

12.g.1/3 **Reason:** {*AI05-0108-1*} The incomplete view of a type does not have a discriminant_part even if the type_declaration does have one. This is necessary because semantic analysis (and the associated dependence on with_clauses) would be necessary to determine the types of the discriminants.

12.g.2/3 {*AI05-0129-1*} No incomplete views of incomplete types are included in the limited view. The rules of 3.10.1 ensure that the completion of any visible incomplete type is declared in the same visible part, so such an incomplete view would simply be redundant.

12.g.3/2 **Discussion:** {*AI95-00217-06*} The implementation model of a limited view is that it can be determined solely from the syntax of the source of the unit, without any semantic analysis. That allows it to be created without the semantic dependences of a full unit, which is necessary for it to break mutual dependences of units.

12.g.4/2 **Ramification:** The limited view does not include package instances and their contents. Semantic analysis of a unit (and dependence on its with_clauses) would be needed to determine the contents of an instance.

12.4/2 The limited view of a library package_declaration is private if that library package_declaration is immediately preceded by the reserved word **private**.

12.5/2 [There is no syntax for declaring limited views of packages, because they are always implicit.] The implicit declaration of a limited view of a library package [is not the declaration of a library unit (the

library package_declaration is); nonetheless, it] is a library_item. The implicit declaration of the limited view of a library package forms an (implicit) compilation unit whose context_clause is empty.

A library package_declaration is the completion of the declaration of its limited view. 12.6/2

To be honest: This is notwithstanding the rule in 3.11.1 that says that implicit declarations don't have completions. 12.h/2

Reason: This rule explains where to find the completions of the incomplete views defined by the limited view. 12.i/2

Legality Rules

The parent unit of a library_item shall be a [library] package or generic [library] package. 13

If a defining_program_unit_name of a given declaration or body has a parent_unit_name, then the given declaration or body shall be a library_item. The body of a program unit shall be a library_item if and only if the declaration of the program unit is a library_item. In a library_unit_renaming_declaration, the [(old)] name shall denote a library_item. 14

Discussion: We could have allowed nested program units to be children of other program units; their semantics would make sense. We disallow them to keep things simpler and because they wouldn't be particularly useful. 14.a

{*AI95-00217-06*} A parent_unit_name [(which can be used within a defining_program_unit_name of a library_item and in the **separate** clause of a subunit)], and each of its prefixes, shall not denote a renaming_declaration. [On the other hand, a name that denotes a library_unit_renaming_declaration is allowed in a nonlimited_with_clause and other places where the name of a library unit is allowed.] 15/2

If a library package is an instance of a generic package, then every child of the library package shall either be itself an instance or be a renaming of a library unit. 16

Discussion: A child of an instance of a given generic unit will often be an instance of a (generic) child of the given generic unit. This is not required, however. 16.a

Reason: Instances are forbidden from having noninstance children for two reasons: 16.b

1. We want all source code that can depend on information from the private part of a library unit to be inside the "subsystem" rooted at the library unit. If an instance of a generic unit were allowed to have a noninstance as a child, the source code of that child might depend on information from the private part of the generic unit, even though it is outside the subsystem rooted at the generic unit. 16.c
2. Disallowing noninstance children simplifies the description of the semantics of children of generic packages. 16.d

{*AI05-0004-1*} A child of a generic library package shall either be itself a generic unit or be a renaming of some other child of the same generic unit. 17/3

A child of a parent generic package shall be instantiated or renamed only within the declarative region of the parent generic. 18

{*AI95-00331-01*} For each child *C* of some parent generic package *P*, there is a corresponding declaration *C* nested immediately within each instance of *P*. For the purposes of this rule, if a child *C* itself has a child *D*, each corresponding declaration for *C* has a corresponding child *D*. [The corresponding declaration for a child within an instance is visible only within the scope of a with_clause that mentions the (original) child generic unit.] 19/2

Implementation Note: Within the child, like anything nested in a generic unit, one can make up-level references to the current instance of its parent, and thereby gain access to the formal parameters of the parent, to the types declared in the parent, etc. This “nesting” model applies even within the generic_formal_part of the child, as it does for a generic child of a nongeneric unit. 19.a

Ramification: Suppose P is a generic library package, and P.C is a generic child of P. P.C can be instantiated inside the declarative region of P. Outside P, P.C can be mentioned only in a with_clause. Conceptually, an instance I of P is a package that has a nested generic unit called I.C. Mentioning P.C in a with_clause allows I.C to be instantiated. I need not be a library unit, and the instantiation of I.C need not be a library unit. If I is a library unit, and an instance of I.C is a child of I, then this instance has to be called something other than C. 19.b

A library subprogram shall not override a primitive subprogram. 20

20.a **Reason:** This prevents certain obscure anomalies. For example, if a library subprogram were to override a subprogram declared in its parent package, then in a compilation unit that depends *in*directly on the library subprogram, the library subprogram could hide the overridden operation from all visibility, but the library subprogram itself would not be visible.

20.b Note that even without this rule, such subprograms would be illegal for tagged types, because of the freezing rules.

21 The defining name of a function that is a compilation unit shall not be an operator_symbol.

21.a **Reason:** Since overloading is not permitted among compilation units, it seems unlikely that it would be useful to define one as an operator. Note that a subunit could be renamed within its parent to be an operator.

Static Semantics

22 A subprogram_renaming_declaration that is a library_unit_renaming_declaration is a renaming-as-declaration, not a renaming-as-body.

23 [There are two kinds of dependences among compilation units:]

24/5 - {*AI12-0445-1*} [The *semantic dependences* (see below) are the ones necessary to check the compile-time rules across compilation unit boundaries; a compilation unit depends semantically on the other compilation units necessary to determine its legality. The visibility rules are based on the semantic dependences.

25 - The *elaboration dependences* (see 10.2) determine the order of elaboration of library_items.]

25.a **Discussion:** Don't confuse these kinds of dependences with the run-time dependences among tasks and masters defined in 9.3, “Task Dependence - Termination of Tasks”.

26/2 {*AI95-00217-06*} A library_item depends semantically upon its parent declaration. A subunit depends semantically upon its parent body. A library_unit_body depends semantically upon the corresponding library_unit_declaration, if any. The declaration of the limited view of a library package depends semantically upon the declaration of the limited view of its parent. The declaration of a library package depends semantically upon the declaration of its limited view. A compilation unit depends semantically upon each library_item mentioned in a with_clause of the compilation unit. In addition, if a given compilation unit contains an attribute_reference of a type defined in another compilation unit, then the given compilation unit depends semantically upon the other compilation unit. The semantic dependence relationship is transitive.

26.a **Discussion:** The “if any” in the third sentence is necessary because library subprograms are not required to have a subprogram_declaration.

26.b **To be honest:** If a given compilation unit contains a choice_parameter_specification, then the given compilation unit depends semantically upon the declaration of Ada.Exceptions.

26.c If a given compilation unit contains a pragma with an argument of a type defined in another compilation unit, then the given compilation unit depends semantically upon the other compilation unit.

26.d **Discussion:** For example, a compilation unit containing X'Address depends semantically upon the declaration of package System.

26.e For the Address attribute, this fixes a hole in Ada 83. Note that in almost all cases, the dependence will need to exist due to with_clauses, even without this rule. Hence, the rule has very little effect on programmers.

26.f Note that the semantic dependence does not have the same effect as a with_clause; in order to denote a declaration in one of those packages, a with_clause will generally be needed.

26.g Note that no special rule is needed for an attribute_definition_clause, since an expression after **use** will require semantic dependence upon the compilation unit containing the type_declaration of interest.

26.h/2 {*AI95-00217-06*} Unlike a full view of a package, a limited view does not depend semantically on units mentioned in with_clauses of the compilation_unit that defines the package. Formally, this is achieved by saying that the limited view has an empty context_clause. This is necessary so that they can be useful for their intended purpose: allowing mutual dependences between packages. The lack of semantic dependence limits the contents of a limited view to the items that can be determined solely from the syntax of the source of the package, without any semantic analysis. That allows it to be created without the semantic dependences of a full package.

Dynamic Semantics

{*AI95-00217-06*} The elaboration of the declaration of the limited view of a package has no effect. 26.1/2

NOTE 1 {*AI12-0442-1*} A simple program can consist of a single compilation unit. A compilation can have no compilation units; for example, its text can consist of pragmas. 27/5

Ramification: Such pragmas cannot have any arguments that are names, by a previous rule of this subclause. A compilation can even be entirely empty, which is probably not useful. 27.a

Some interesting properties of the three kinds of dependence: The elaboration dependences also include the semantic dependences, except that subunits are taken together with their parents. The semantic dependences partly determine the order in which the compilation units appear in the environment at compile time. At run time, the order is partly determined by the elaboration dependences. 27.b

The model whereby a child is inside its parent's declarative region, after the parent's declaration, as explained in 8.1, has the following ramifications: 27.c

- The restrictions on "early" use of a private type (RM83-7.4.1(4)) or a deferred constant (RM83-7.4.3(2)) do not apply to uses in child units, because they follow the full declaration. 27.d
- A library subprogram is never primitive, even if its profile includes a type declared immediately within the parent's package_specification, because the child is not declared immediately within the same package_specification as the type (so it doesn't declare a new primitive subprogram), and because the child is forbidden from overriding an old primitive subprogram. It is immediately within the same declarative region, but not the same package_specification. Thus, for a tagged type, it is not possible to call a child subprogram in a dispatching manner. (This is also forbidden by the freezing rules.) Similarly, it is not possible for the user to declare primitive subprograms of the types declared in the declaration of Standard, such as Integer (even if the rules were changed to allow a library unit whose name is an operator symbol). 27.e
- When the parent unit is "used" the simple names of the with'd child units are directly visible (see 8.4, "Use Clauses"). 27.f
- When a parent body with's its own child, the defining name of the child is directly visible, and the parent body is not allowed to include a declaration of a homograph of the child unit immediately within the declarative_part of the body (RM83-8.3(17)). 27.g

Note that "declaration of a library unit" is different from "library_unit_declaration" — the former includes subprogram_body. Also, we sometimes really mean "declaration of a view of a library unit", which includes library_unit_renaming_declarations. 27.h

The visibility rules generally imply that the renamed view of a library_unit_renaming_declaration has to be mentioned in a with_clause of the library_unit_renaming_declaration. 27.i

To be honest: The real rule is that the renamed library unit has to be visible in the library_unit_renaming_declaration. 27.j

Reason: In most cases, "has to be visible" means there has to be a with_clause. However, it is possible in obscure cases to avoid the need for a with_clause; in particular, a compilation unit such as "**package** P.Q **renames** P;" is legal with no with_clauses (though not particularly interesting). ASCII is physically nested in Standard, and so is not a library unit, and cannot be renamed as a library unit. 27.k

NOTE 2 The designator of a library function cannot be an operator_symbol, but a nonlibrary renaming_declaration is allowed to rename a library function as an operator. Within a partition, two library subprograms are required to have distinct names and hence cannot overload each other. However, renaming_declarations are allowed to define overloaded names for such subprograms, and a locally declared subprogram is allowed to overload a library subprogram. The expanded name Standard.L can be used to denote a root library unit L (unless the declaration of Standard is hidden) since root library unit declarations occur immediately within the declarative region of package Standard. 28

Examples

Examples of library units: 29

```
package Rational_Numbers.IO is   -- public child of Rational_Numbers, see 7.1
   procedure Put(R : in  Rational);
   procedure Get(R : out Rational);
end Rational_Numbers.IO;
```
30

```
private procedure Rational_Numbers.Reduce(R : in out Rational);
                                 -- private child of Rational_Numbers
```
31

```
with Rational_Numbers.Reduce;    -- refer to a private child
package body Rational_Numbers is
   ...
end Rational_Numbers;
```
32

33
```
with Rational_Numbers.IO; use Rational_Numbers;
with Ada.Text_io;                -- see A.10
procedure Main is                -- a root library procedure
   R : Rational;
begin
   R := 5/3;                     -- construct a rational number, see 7.1
   Ada.Text_IO.Put("The answer is: ");
   IO.Put(R);
   Ada.Text_IO.New_Line;
end Main;
```

34
```
with Rational_Numbers.IO;
package Rational_IO renames Rational_Numbers.IO;
                                 -- a library unit renaming declaration
```

35 Each of the above library_items can be submitted to the compiler separately.

35.a **Discussion:** *Example of a generic package with children:*

35.b
```
generic
   type Element is private;
   with function Image(E : Element) return String;
package Generic_Bags is
   type Bag is limited private; -- A bag of Elements.
   procedure Add(B : in out Bag; E : Element);
   function Bag_Image(B : Bag) return String;
private
   type Bag is ...;
end Generic_Bags;
```

35.c
```
generic
package Generic_Bags.Generic_Iterators is
   ... -- various additional operations on Bags.
```

35.d
```
   generic
      with procedure Use_Element(E : in Element);
         -- Called once per bag element.
   procedure Iterate(B : in Bag);
end Generic_Bags.Generic_Iterators;
```

35.e A package that instantiates the above generic units:

35.f
```
with Generic_Bags;
with Generic_Bags.Generic_Iterators;
package My_Abstraction is
    type My_Type is ...;
    function Image(X : My_Type) return String;
    package Bags_Of_My_Type is new Generic_Bags(My_Type, Image);
    package Iterators_Of_Bags_Of_My_Type is new Bags_Of_My_Type.Generic_Iterators;
end My_Abstraction;
```

35.g In the above example, Bags_Of_My_Type has a nested generic unit called Generic_Iterators. The second with_clause makes that nested unit visible.

35.h Here we show how the generic body could depend on one of its own children:

35.i
```
with Generic_Bags.Generic_Iterators;
package body Generic_Bags is
   procedure Add(B : in out Bag; E : Element) is ... end Add;
```

35.j
```
   package Iters is new Generic_Iterators;
```

35.k
```
   function Bag_Image(B : Bag) return String is
      Buffer : String(1..10_000);
      Last : Integer := 0;
```

35.l
```
      procedure Append_Image(E : in Element) is
         Im : constant String := Image(E);
      begin
         if Last /= 0 then -- Insert a comma.
            Last := Last + 1;
            Buffer(Last) := ',';
         end if;
         Buffer(Last+1 .. Last+Im'Length) := Im;
         Last := Last + Im'Length;
      end Append_Image;
```

```
      procedure Append_All is new Iters.Iterate(Append_Image);
   begin
      Append_All(B);
      return Buffer(1..Last);
   end Bag_Image;
end Generic_Bags;
```

35.m

Extensions to Ada 83

The syntax rule for library_item is modified to allow the reserved word **private** before a library_unit_declaration. 35.n

Children (other than children of Standard) are new in Ada 95. 35.o

Library unit renaming is new in Ada 95. 35.p

Wording Changes from Ada 83

Standard is considered a library unit in Ada 95. This simplifies the descriptions, since it implies that the parent of each library unit is a library unit. (Standard itself has no parent, of course.) As in Ada 83, the language does not define any way to recompile Standard, since the name given in the declaration of a library unit is always interpreted in relation to Standard. That is, an attempt to compile a package Standard would result in Standard.Standard. 35.q

Extensions to Ada 95

{*AI95-00217-06*} The concept of a limited view is new. Combined with limited_with_clauses (see 10.1.2), they facilitate construction of mutually recursive types in multiple packages. 35.r/2

Wording Changes from Ada 95

{*AI95-00331-01*} Clarified the wording so that a grandchild generic unit will work as expected. 35.s/2

Wording Changes from Ada 2005

{*AI05-0108-1*} {*AI05-0129-1*} **Correction:** Clarified the wording so that it is clear that limited views of types never have discriminants and never are of incomplete types. 35.t/3

10.1.2 Context Clauses - With Clauses

[A context_clause is used to specify the library_items whose names are needed within a compilation unit.] 1

Language Design Principles

The reader should be able to understand a context_clause without looking ahead. Similarly, when compiling a context_clause, the compiler should not have to look ahead at subsequent context_items, nor at the compilation unit to which the context_clause is attached. (We have not completely achieved this.) 1.a

{*AI95-00217-06*} A *ripple effect* occurs when the legality of a compilation unit could be affected by adding or removing an otherwise unneeded with_clause on some compilation unit on which the unit depends, directly or indirectly. We try to avoid ripple effects because they make understanding and maintenance more difficult. However, ripple effects can occur because of direct visibility (as in child units); this seems impossible to eliminate. The ripple effect for with_clauses is somewhat similar to the Beaujolais effect (see 8.4) for use_clauses, which we also try to avoid. 1.b/2

Syntax

context_clause ::= {context_item} 2

context_item ::= with_clause | use_clause 3

{*AI95-00217-06*} {*AI95-00262-01*} with_clause ::= limited_with_clause | nonlimited_with_clause 4/2

limited_with_clause ::= **limited** [**private**] **with** *library_unit*_name {, *library_unit*_name}; 4.1/2

nonlimited_with_clause ::= [**private**] **with** *library_unit*_name {, *library_unit*_name}; 4.2/2

Discussion: {*AI95-00217-06*} A limited_with_clause makes a limited view of a unit visible. 4.a/2

4.b/2 {*AI95-00262-01*} A with_clause containing the reserved word **private** is called a *private with_clause*. It can be thought of as making items visible only in the private part, although it really makes items visible everywhere except the visible part. It can be used both for documentation purposes (to say that a unit is not used in the visible part), and to allow access to private units that otherwise would be prohibited.

Name Resolution Rules

5 The *scope* of a with_clause that appears on a library_unit_declaration or library_unit_renaming_-declaration consists of the entire declarative region of the declaration[, which includes all children and subunits]. The scope of a with_clause that appears on a body consists of the body[, which includes all subunits].

5.a/2 **Discussion:** {*AI95-00262-01*} Suppose a nonprivate with_clause of a public library unit mentions one of its private siblings. (This is only allowed on the body of the public library unit.) We considered making the scope of that with_clause not include the visible part of the public library unit. (This would only matter for a subprogram_body, since those are the only kinds of body that have a visible part, and only if the subprogram_body completes a subprogram_declaration, since otherwise the with_clause would be illegal.) We did not put in such a rule for two reasons: (1) It would complicate the wording of the rules, because we would have to split each with_clause into pieces, in order to correctly handle "**with** P, Q;" where P is public and Q is private. (2) The conformance rules prevent any problems. It doesn't matter if a type name in the spec of the body denotes the completion of a private_type_declaration.

5.b A with_clause also affects visibility within subsequent use_clauses and pragmas of the same context_clause, even though those are not in the scope of the with_clause.

6/2 {*AI95-00217-06*} A library_item (and the corresponding library unit) is *named* in a with_clause if it is denoted by a *library_unit*_name in the with_clause. A library_item (and the corresponding library unit) is *mentioned* in a with_clause if it is named in the with_clause or if it is denoted by a prefix in the with_clause.

6.a **Discussion:** With_clauses control the visibility of declarations or renamings of library units. Mentioning a root library unit in a with_clause makes its declaration directly visible. Mentioning a nonroot library unit makes its declaration visible. See Clause 8 for details.

6.b/2 {*AI95-00114-01*} Note that this rule implies that "**with** A.B.C;" is almost equivalent to "**with** A, A.B, A.B.C;". The reason for making a with_clause apply to all the ancestor units is to avoid "visibility holes" — situations in which an inner program unit is visible while an outer one is not. Visibility holes would cause semantic complexity and implementation difficulty. (This is not exactly equivalent because the latter with_clause names A and A.B, while the previous one does not. Whether a unit is "named" does not have any effect on visibility, however, so it is equivalent for visibility purposes.)

7 [Outside its own declarative region, the declaration or renaming of a library unit can be visible only within the scope of a with_clause that mentions it. The visibility of the declaration or renaming of a library unit otherwise follows from its placement in the environment.]

Legality Rules

8/2 {*AI95-00262-01*} If a with_clause of a given compilation_unit mentions a private child of some library unit, then the given compilation_unit shall be one of:

9/2 - {*AI95-00262-01*} the declaration, body, or subunit of a private descendant of that library unit;

10/2 - {*AI95-00220-01*} {*AI95-00262-01*} the body or subunit of a public descendant of that library unit, but not a subprogram body acting as a subprogram declaration (see 10.1.4); or

11/2 - {*AI95-00262-01*} the declaration of a public descendant of that library unit, in which case the with_clause shall include the reserved word **private**.

11.a/2 **Reason:** {*AI95-00262-01*} The purpose of this rule is to prevent a private child from being visible from outside the subsystem rooted at its parent. A private child can be semantically depended-on without violating this principle if it is used in a private with_clause.

11.b **Discussion:** This rule violates the one-pass context_clauses Language Design Principle. We rationalize this by saying that at least that Language Design Principle works for legal compilation units.

Example: 11.c

```
package A is                                                    11.d
end A;

package A.B is                                                  11.e
end A.B;

private package A.B.C is                                        11.f
end A.B.C;

package A.B.C.D is                                              11.g
end A.B.C.D;

with A.B.C; -- (1)                                              11.h
private package A.B.X is
end A.B.X;

package A.B.Y is                                                11.i
end A.B.Y;

with A.B.C; -- (2)                                              11.j
package body A.B.Y is
end A.B.Y;

private with A.B.C; -- (3)                                      11.j.1/2
package A.B.Z is
end A.B.Z;
```

{*AI95-00262-01*} (1) is OK because it's a private child of A.B — it would be illegal if we made A.B.X a public child of A.B. (2) is OK because it's the body of a child of A.B. (3) is OK because it's a child of A.B, and it is a private with_clause. It would be illegal to say "**with** A.B.C;" on any library_item whose name does not start with "A.B". Note that mentioning A.B.C.D in a with_clause automatically mentions A.B.C as well, so "**with** A.B.C.D;" is illegal in the same places as "**with** A.B.C;". 11.k/2

{*AI05-0005-1*} {*AI95-00262-01*} {*AI95-00262-01*} {*AI05-0077-1*} {*AI05-0122-1*} {*AI12-0261-1*} A name denoting a library_item (or the corresponding declaration for a child of a generic within an instance — see 10.1.1), if it is visible only due to being mentioned in one or more with_clauses of a unit *U* that include the reserved word **private**, shall appear only within: 12/5

- a private part; 13/2
- {*AI12-0261-1*} a body of a public descendant of *U*, but not within the subprogram_specification of a body of a subprogram that is a public descendant of *U*; 14/5
- {*AI12-0261-1*} a private descendant of *U* or its body; or 15/5
- a pragma within a context clause. 16/2

Ramification: These rules apply only if all of the with_clauses that mention the name include the reserved word **private**. They do not apply if the name is mentioned in any with_clause that does not include **private**. 16.a/2

Reason: {*AI05-0077-1*} These rules make the library_item visible anywhere that is not visible outside the subsystem rooted at the compilation_unit having the private with_clause, including private parts of packages nested in the visible part, private parts of child packages, the visible part of private children, and context clause pragmas like Elaborate_All. 16.b/3

We considered having the scope of a private with_clause not include the visible part. However, that rule would mean that moving a declaration between the visible part and the private part could change its meaning from one legal interpretation to a different legal interpretation. For example: 16.c/2

```
package A is                                                    16.d/2
    function B return Integer;
end A;

function B return Integer;                                      16.e/2

with A;                                                         16.f/2
private with B;
package C is
    use A;
    V1 : Integer := B; -- (1)
private
    V2 : Integer := B; -- (2)
end C;
```

If we say that library subprogram B is not in scope in the visible part of C, then the B at (1) resolves to A.B, while (2) resolves to library unit B. Simply moving a declaration could silently change its meaning. With the legality rule defined above, the B at (1) is illegal. If the user really meant A.B, they still can say that. 16.g/2

17/2 {*AI95-00217-06*} [A library_item mentioned in a limited_with_clause shall be the implicit declaration of the limited view of a library package, not the declaration of a subprogram, generic unit, generic instance, or a renaming.]

17.a/2 **Proof:** This is redundant because only such implicit declarations are visible in a limited_with_clause. See 10.1.6.

18/2 {*AI95-00217-06*} {*AI95-00412-01*} A limited_with_clause shall not appear on a library_unit_body, subunit, or library_unit_renaming_declaration.

18.a/2 **Reason:** {*AI95-00412-01*} We don't allow a limited_with_clause on a library_unit_renaming_declaration because it would be useless and therefore probably is a mistake. A renaming cannot appear in a limited_with_clause (by the rule prior to this one), and a renaming of a limited view cannot appear in a nonlimited_with_clause (because the name would not be within the scope of a with_clause denoting the package, see 8.5.3). Nor could it be the parent of another unit. That doesn't leave anywhere that the name of such a renaming **could** appear, so we simply make writing it illegal.

19/2 {*AI95-00217-06*} A limited_with_clause that names a library package shall not appear:

20/3 - {*AI95-00217-06*} {*AI05-0040-1*} in the context_clause for the explicit declaration of the named library package or any of its descendants;

20.a/2 **Reason:** We have to explicitly disallow

20.b/2
```
limited with P;
package P is ...
```

20.c/2 as we can't depend on the semantic dependence rules to do it for us as with regular withs. This says “named” and not “mentioned” in order that

20.d/2
```
limited private with P.Child;
package P is ...
```

20.e/2 can be used to allow a mutual dependence between the private part of P and the private child P.Child, which occurs in interfacing and other problems. Since the child always semantically depends on the parent, this is the only way such a dependence can be broken.

20.f/3 {*AI05-0040-1*} The part about descendants catches examples like

20.g/3
```
limited with P;
package P.Child is ...
```

21/3 - {*AI95-00217-06*} {*AI05-0077-1*} {*AI05-0262-1*} within a context_clause for a library_item that is within the scope of a nonlimited_with_clause that mentions the same library package; or

21.a.1/3 **Ramification:** {*AI05-0077-1*} This applies to nonlimited_withclauses found in the same context_clause, as well as nonlimited_withclauses found on parent units.

21.a/3 **Reason:** {*AI05-0077-1*} Such a limited_with_clause could have no effect, and would be confusing. If a nonlimited_with_clause for the same package is inherited from a parent unit or given in the context_clause, the full view is available, which strictly provides more information than the limited view.

22/3 - {*AI95-00217-06*} {*AI05-0077-1*} {*AI05-0262-1*} within a context_clause for a library_item that is within the scope of a use_clause that names an entity declared within the declarative region of the library package.

22.a.1/3 **Ramification:** {*AI05-0077-1*} This applies to use_clauses found in the same context_clause, as well as use_clauses found in (or on) parent units.

22.a/2 **Reason:** This prevents visibility issues, where whether an entity is an incomplete or full view depends on how the name of the entity is written. The limited_with_clause cannot be useful, as we must have the full view available in the parent in order for the use_clause to be legal.

23/2 NOTE {*AI95-00217-06*} A library_item mentioned in a nonlimited_with_clause of a compilation unit is visible within the compilation unit and hence acts just like an ordinary declaration. Thus, within a compilation unit that mentions its declaration, the name of a library package can be given in use_clauses and can be used to form expanded names, a library subprogram can be called, and instances of a generic library unit can be declared. If a child of a parent generic package is mentioned in a nonlimited_with_clause, then the corresponding declaration nested within each visible instance is visible within the compilation unit. Similarly, a library_item mentioned in a limited_with_clause of a compilation unit is visible within the compilation unit and thus can be used to form expanded names.

23.a **Ramification:** The rules given for with_clauses are such that the same effect is obtained whether the name of a library unit is mentioned once or more than once by the applicable with_clauses, or even within a given with_clause.

If a with_clause mentions a library_unit_renaming_declaration, it only "mentions" the prefixes appearing explicitly in the with_clause (and the renamed view itself); the with_clause is not defined to mention the ancestors of the renamed entity. Thus, if X renames Y.Z, then "with X;" does not make the declarations of Y or Z visible. Note that this does not cause the dreaded visibility holes mentioned above. 23.b

Examples

{AI12-0429-1} Examples of use of with clauses, limited with clauses, and private with clauses: 24/5

```
{AI95-00433-01} package Office is                                                    25/2
end Office;

{AI95-00433-01} with Ada.Strings.Unbounded;                                          26/2
package Office.Locations is
   type Location is new Ada.Strings.Unbounded.Unbounded_String;
end Office.Locations;

{AI95-00433-01} limited with Office.Departments;   -- types are incomplete           27/2
private with Office.Locations;     -- only visible in private part
package Office.Employees is
   type Employee is private;

   function Dept_Of(Emp : Employee) return access Departments.Department;            28/2
   procedure Assign_Dept(Emp  : in out Employee;
                         Dept : access Departments.Department);

   ...                                                                               29/2
private
   type Employee is
      record
         Dept : access Departments.Department;
         Loc : Locations.Location;
         ...
      end record;
end Office.Employees;

{AI12-0178-1} limited with Office.Employees;                                         30/5
package Office.Departments is
   type Department is ...;

   function Manager_Of(Dept : Department) return access Employees.Employee;          31/2
   procedure Assign_Manager(Dept : in out Department;
                            Mgr  : access Employees.Employee);
   ...
end Office.Departments;
```

{AI95-00433-01} {AI12-0429-1} {AI12-0440-1} The limited_with_clause *can be used to support mutually dependent abstractions that are split across multiple packages. In this case, an employee is assigned to a department, and a department has a manager who is an employee. If a* with_clause *with the reserved word* ***private*** *appears on one library unit and mentions a second library unit, it provides visibility to the second library unit, but restricts that visibility to the private part and body of the first unit. The compiler checks that no use is made of the second unit in the visible part of the first unit.* 32/5

Extensions to Ada 83

The syntax rule for with_clause is modified to allow expanded name notation. 32.a

A use_clause in a context_clause may be for a package (or type) nested in a library package. 32.b

Wording Changes from Ada 83

The syntax rule for context_clause is modified to more closely reflect the semantics. The Ada 83 syntax rule implies that the use_clauses that appear immediately after a particular with_clause are somehow attached to that with_clause, which is not true. The new syntax allows a use_clause to appear first, but that is prevented by a textual rule that already exists in Ada 83. 32.c

The concept of "scope of a with_clause" (which is a region of text) replaces RM83's notion of "apply to" (a with_clause applies to a library_item) The visibility rules are interested in a region of text, not in a set of compilation units. 32.d

32.e No need to define “apply to” for use_clauses. Their semantics are fully covered by the “scope (of a use_clause)” definition in 8.4.

Incompatibilities With Ada 95

32.f/2 {*AI95-00220-01*} **Amendment Correction:** A subprogram body acting as a declaration cannot **with** a private child unit. This would allow public export of types declared in private child packages, and thus cannot be allowed. This was allowed by mistake in Ada 95; a subprogram that does this will now be illegal.

Extensions to Ada 95

32.g/2 {*AI95-00217-06*} limited_with_clauses are new. They make a limited view of a package visible, where all of the types in the package are incomplete. They facilitate construction of mutually recursive types in multiple packages.

32.h/3 {*AI95-00262-01*} {*AI05-0077-1*} The syntax rules for with_clause are modified to allow the reserved word **private**. Private with_clauses do not allow the use of their library_item in the visible part of their compilation_unit. They also allow using private units in more locations than in Ada 95.

Incompatibilities With Ada 2005

32.i/3 {*AI05-0040-1*} **Correction:** Added missing rule that a limited with clause cannot name an ancestor unit. This is incompatible if an Ada 2005 program does this, but as this is a new Ada 2005 feature and the unintentionally allowed capability is not useful, the incompatibility is very unlikely to occur in practice.

Wording Changes from Ada 2005

32.j/3 {*AI05-0077-1*} **Correction:** Fixed wording so that we are not checking whether something in a context_clause is “within the scope of” something, as context_clauses are never included in anything's scope. The intended meaning is unchanged, however.

32.k/3 {*AI05-0122-1*} **Correction:** Fixed wording so the rules for private with clauses also apply to "sprouted" generic child units.

Wording Changes from Ada 2012

32.l/5 {*AI12-0261-1*} **Correction:** Fixed wording so the privately withed units are visible in the subprogram specification of the body of a private descendant; otherwise, the private specification is legal but the completion is not.

10.1.3 Subunits of Compilation Units

1 [Subunits are like child units, with these (important) differences: subunits support the separate compilation of bodies only (not declarations); the parent contains a body_stub to indicate the existence and place of each of its subunits; declarations appearing in the parent's body can be visible within the subunits.]

Syntax

2
```
body_stub ::=
   subprogram_body_stub | package_body_stub
 | task_body_stub | protected_body_stub
```

3/3 {*AI95-00218-03*} {*AI05-0267-1*}
```
subprogram_body_stub ::=
   [overriding_indicator]
   subprogram_specification is separate
     [aspect_specification];
```

3.a **Discussion:** Although this syntax allows a parent_unit_name, that is disallowed by 10.1.1, “Compilation Units - Library Units”.

4/3 {*AI05-0267-1*}
```
package_body_stub ::=
  package body defining_identifier is separate
    [aspect_specification];
```

5/3 {*AI05-0267-1*}
```
task_body_stub ::=
```

task body defining_identifier **is separate**
[aspect_specification];

{*AI05-0267-1*} protected_body_stub ::= 6/3
protected body defining_identifier **is separate**
[aspect_specification];

subunit ::= **separate** (parent_unit_name) proper_body 7

Legality Rules

{*AI95-00243-01*} The *parent body* of a subunit is the body of the program unit denoted by its parent_unit_name. The term *subunit* is used to refer to a subunit and also to the proper_body of a subunit. The *subunits of a program unit* include any subunit that names that program unit as its parent, as well as any subunit that names such a subunit as its parent (recursively). 8/2

Reason: {*AI95-00243-01*} We want any rule that applies to a subunit to apply to a subunit of a subunit as well. 8.a.1/2

Term entry: subunit — body of a program unit that can be compiled separately from its enclosing program unit 8.a/5

The parent body of a subunit shall be present in the current environment, and shall contain a corresponding body_stub with the same defining_identifier as the subunit. 9

Discussion: This can't be a Name Resolution Rule, because a subunit is not a complete context. 9.a

{*AI05-0004-1*} A package_body_stub shall be the completion of a package_declaration or generic_package_declaration; a task_body_stub shall be the completion of a task declaration; a protected_body_stub shall be the completion of a protected declaration. 10/3

{*AI12-0444-1*} In contrast, a subprogram_body_stub can be defined without it being the completion of a previous declaration, [in which case the _stub declares the subprogram]. If the _stub is a completion, it shall be the completion of a subprogram_declaration or generic_subprogram_declaration. The profile of a subprogram_body_stub that completes a declaration shall conform fully to that of the declaration. 11/5

Discussion: The part about subprogram_body_stubs echoes the corresponding rule for subprogram_bodies in 6.3, "Subprogram Bodies". 11.a

A subunit that corresponds to a body_stub shall be of the same kind (package_, subprogram_, task_, or protected_) as the body_stub. The profile of a subprogram_body subunit shall be fully conformant to that of the corresponding body_stub. 12

A body_stub shall appear immediately within the declarative_part of a compilation unit body. This rule does not apply within an instance of a generic unit. 13

Discussion: This is a methodological restriction; that is, it is not necessary for the semantics of the language to make sense. 13.a

The defining_identifiers of all body_stubs that appear immediately within a particular declarative_part shall be distinct. 14

Post-Compilation Rules

For each body_stub, there shall be a subunit containing the corresponding proper_body. 15

NOTE The rules in 10.1.4, "The Compilation Process" say that a body_stub is equivalent to the corresponding proper_body. This implies: 16

- Visibility within a subunit is the visibility that would be obtained at the place of the corresponding body_stub (within the parent body) if the context_clause of the subunit were appended to that of the parent body. 17

  Ramification: Recursively. Note that this transformation might make the parent illegal; hence it is not a true equivalence, but applies only to visibility within the subunit. 17.a

- The effect of the elaboration of a body_stub is to elaborate the subunit. 18

18.a **Ramification:** The elaboration of a subunit is part of its parent body's elaboration, whereas the elaboration of a child unit is not part of its parent declaration's elaboration.

18.b **Ramification:** A library_item that is mentioned in a with_clause of a subunit can be hidden (from direct visibility) by a declaration (with the same identifier) given in the subunit. Moreover, such a library_item can even be hidden by a declaration given within the parent body since a library unit is declared in its parent's declarative region; this however does not affect the interpretation of the with_clauses themselves, since only library_items are visible or directly visible in with_clauses.

18.c The body of a protected operation cannot be a subunit. This follows from the syntax rules. The body of a protected unit can be a subunit.

Examples

19/5 *{AI12-0429-1} Example that defines package Parent without subunits:*

20
```
package Parent is
    procedure Inner;
end Parent;
```

21
```
with Ada.Text_IO;
package body Parent is
    Variable : String := "Hello, there.";
    procedure Inner is
    begin
        Ada.Text_IO.Put_Line(Variable);
    end Inner;
end Parent;
```

22/5 *{AI12-0429-1} {AI12-0440-1} Example showing how the body of procedure Inner can be turned into a subunit by rewriting the package body as follows (with the declaration of Parent remaining the same):*

23
```
package body Parent is
    Variable : String := "Hello, there.";
    procedure Inner is separate;
end Parent;
```

24
```
with Ada.Text_IO;
separate(Parent)
procedure Inner is
begin
    Ada.Text_IO.Put_Line(Variable);
end Inner;
```

Extensions to Ada 83

24.a Subunits of the same ancestor library unit are no longer restricted to have distinct identifiers. Instead, we require only that the full expanded names be distinct.

Extensions to Ada 95

24.b/2 *{AI95-00218-03}* An overriding_indicator (see 8.3.1) is allowed on a subprogram stub.

Wording Changes from Ada 95

24.c/2 *{AI95-00243-01}* Clarified that a subunit of a subunit is still a subunit.

Extensions to Ada 2005

24.d/3 *{AI05-0267-1}* An optional aspect_specification can be used in a body_stub. This is described in 13.1.1.

10.1.4 The Compilation Process

1 Each compilation unit submitted to the compiler is compiled in the context of an *environment* declarative_part (or simply, an *environment*), which is a conceptual declarative_part that forms the outermost declarative region of the context of any compilation. At run time, an environment forms the declarative_part of the body of the environment task of a partition (see 10.2, “Program Execution”).

Ramification: At compile time, there is no particular construct that the declarative region is considered to be nested within — the environment is the universe. 1.a

To be honest: The environment is really just a portion of a declarative_part, since there might, for example, be bodies that do not yet exist. 1.b

{*AI12-0445-1*} The declarative_items of the environment are library_items appearing in an order such that there are no forward semantic dependences. Each included subunit occurs in place of the corresponding stub. The visibility rules apply as if the environment were the outermost declarative region, except that with_clauses are necessary to make declarations of library units visible (see 10.1.2). 2/5

{*AI95-00217-06*} The mechanisms for creating an environment and for adding and replacing compilation units within an environment are implementation defined. The mechanisms for adding a compilation unit mentioned in a limited_with_clause to an environment are implementation defined. 3/2

Implementation defined: The mechanisms for creating an environment and for adding and replacing compilation units. 3.a

Implementation defined: The mechanisms for adding a compilation unit mentioned in a limited_with_clause to an environment. 3.a.1/2

Ramification: The traditional model, used by most Ada 83 implementations, is that one places a compilation unit in the environment by compiling it. Other models are possible. For example, an implementation might define the environment to be a directory; that is, the compilation units in the environment are all the compilation units in the source files contained in the directory. In this model, the mechanism for replacing a compilation unit with a new one is simply to edit the source file containing that compilation unit. 3.b

Name Resolution Rules

{*8652/0032*} {*AI95-00192-01*} {*AI05-0264-1*} If a library_unit_body that is a subprogram_body is submitted to the compiler, it is interpreted only as a completion if a library_unit_declaration with the same defining_program_unit_name already exists in the environment for a subprogram other than an instance of a generic subprogram or for a generic subprogram (even if the profile of the body is not type conformant with that of the declaration); otherwise, the subprogram_body is interpreted as both the declaration and body of a library subprogram. 4/3

Ramification: The principle here is that a subprogram_body should be interpreted as only a completion if and only if it "might" be legal as the completion of some preexisting declaration, where "might" is defined in a way that does not require overload resolution to determine. 4.a

Hence, if the preexisting declaration is a subprogram_declaration or generic_subprogram_declaration, we treat the new subprogram_body as its completion, because it "might" be legal. If it turns out that the profiles don't fully conform, it's an error. In all other cases (the preexisting declaration is a package or a generic package, or an instance of a generic subprogram, or a renaming, or a "spec-less" subprogram, or in the case where there is no preexisting thing), the subprogram_body declares a new subprogram. 4.b

See also AI83-00266/09. 4.c

Legality Rules

When a compilation unit is compiled, all compilation units upon which it depends semantically shall already exist in the environment; the set of these compilation units shall be *consistent* in the sense that the new compilation unit shall not semantically depend (directly or indirectly) on two different versions of the same compilation unit, nor on an earlier version of itself. 5

Discussion: For example, if package declarations A and B both say "**with** X;", and the user compiles a compilation unit that says "**with** A, B;", then the A and B have to be talking about the same version of X. 5.a

Ramification: What it means to be a "different version" is not specified by the language. In some implementations, it means that the compilation unit has been recompiled. In others, it means that the source of the compilation unit has been edited in some significant way. 5.b

Note that an implementation cannot require the existence of compilation units upon which the given one does not semantically depend. For example, an implementation is required to be able to compile a compilation unit that says "**with** A;" when A's body does not exist. It has to be able to detect errors without looking at A's body. 5.c

5.d/3 {*AI05-0229-1*} Similarly, the implementation has to be able to compile a call to a subprogram for which aspect Inline has been specified without seeing the body of that subprogram — inlining would not be achieved in this case, but the call is still legal.

5.e/3 {*AI95-00217-06*} {*AI05-0005-1*} The consistency rule applies to limited views as well as the full view of a compilation unit. That means that an implementation needs a way to enforce consistency of limited views, not just of full views.

Implementation Permissions

6/2 {*AI95-00217-06*} The implementation may require that a compilation unit be legal before it can be mentioned in a limited_with_clause or it can be inserted into the environment.

7/3 {*AI95-00214-01*} {*AI05-0229-1*} When a compilation unit that declares or renames a library unit is added to the environment, the implementation may remove from the environment any preexisting library_item or subunit with the same full expanded name. When a compilation unit that is a subunit or the body of a library unit is added to the environment, the implementation may remove from the environment any preexisting version of the same compilation unit. When a compilation unit that contains a body_stub is added to the environment, the implementation may remove any preexisting library_item or subunit with the same full expanded name as the body_stub. When a given compilation unit is removed from the environment, the implementation may also remove any compilation unit that depends semantically upon the given one. If the given compilation unit contains the body of a subprogram for which aspect Inline is True, the implementation may also remove any compilation unit containing a call to that subprogram.

7.a/3 **Ramification:** {*AI05-0005-1*} The permissions given in this paragraph correspond to the traditional model, where compilation units enter the environment by being compiled into it, and the compiler checks their legality at that time. An implementation model in which the environment consists of all source files in a given directory might not want to take advantage of these permissions. Compilation units would not be checked for legality as soon as they enter the environment; legality checking would happen later, when compilation units are compiled. In this model, compilation units might never be automatically removed from the environment; they would be removed when the user explicitly deletes a source file.

7.b Note that the rule is recursive: if the above permission is used to remove a compilation unit containing an inlined subprogram call, then compilation units that depend semantically upon the removed one may also be removed, and so on.

7.c Note that here we are talking about dependences among existing compilation units in the environment; it doesn't matter what with_clauses are attached to the new compilation unit that triggered all this.

7.d/3 {*AI05-0229-1*} An implementation may have other modes in which compilation units in addition to the ones mentioned above are removed. For example, an implementation might inline subprogram calls without an explicit aspect Inline. If so, it either has to have a mode in which that optimization is turned off, or it has to automatically regenerate code for the inlined calls without requiring the user to resubmit them to the compiler.

7.d.1/2 **Discussion:** {*8652/0108*} {*AI95-00077-01*} {*AI95-00114-01*} In the standard mode, implementations may only remove units from the environment for one of the reasons listed here, or in response to an explicit user command to modify the environment. It is not intended that the act of compiling a unit is one of the "mechanisms" for removing units other than those specified by this document.

7.e/2 {*AI95-00214-01*} These rules are intended to ensure that an implementation never need keep more than one compilation unit with any full expanded name. In particular, it is not necessary to be able to have a subunit and a child unit with the same name in the environment at one time.

8 NOTE 1 The rules of the language are enforced across compilation and compilation unit boundaries, just as they are enforced within a single compilation unit.

8.a/3 **Ramification:** {*AI05-0299-1*} Note that Clause 1 requires an implementation to detect illegal compilation units at compile time.

9/5 NOTE 2 {*AI12-0442-1*} An implementation can support a concept of a *library*, which contains library_items. If multiple libraries are supported, the implementation can document how a single environment is constructed when a compilation unit is submitted to the compiler. Naming conflicts between different libraries can, for example, be resolved by treating each library as the root of a hierarchy of child library units.

9.a **Implementation Note:** Alternatively, naming conflicts could be resolved via some sort of hiding rule.

Discussion: For example, the implementation might support a command to import library Y into library X. If a root library unit called LU (that is, Standard.LU) exists in Y, then from the point of view of library X, it could be called Y.LU. X might contain library units that say, "**with** Y.LU;". 9.b

NOTE 3 A compilation unit containing an instantiation of a separately compiled generic unit does not semantically depend on the body of the generic unit. Therefore, replacing the generic body in the environment does not result in the removal of the compilation unit containing the instantiation. 10

Implementation Note: Therefore, implementations have to be prepared to automatically instantiate generic bodies at link-time, as needed. This might imply a complete automatic recompilation, but it is the intent of the language that generic bodies can be (re)instantiated without forcing all of the compilation units that semantically depend on the compilation unit containing the instantiation to be recompiled. 10.a

Extensions to Ada 83

{*AI95-00077-01*} {*AI95-00114-01*} Ada 83 allowed implementations to require that the body of a generic unit be available when the instantiation is compiled; that permission is dropped in Ada 95. This isn't really an extension (it doesn't allow Ada users to write anything that they couldn't in Ada 83), but there isn't a more appropriate category, and it does allow users more flexibility when developing programs. 10.b/2

Wording Changes from Ada 95

{*8652/0032*} {*AI95-00192-01*} **Corrigendum:** The wording was clarified to ensure that a subprogram_body is not considered a completion of an instance of a generic subprogram. 10.c/2

{*AI95-00214-01*} The permissions to remove a unit from the environment were clarified to ensure that it is never necessary to keep multiple (sub)units with the same full expanded name in the environment. 10.d/2

{*AI95-00217-06*} Units mentioned in a limited_with_clause were added to several rules; limited views have the same presence in the environment as the corresponding full views. 10.e/2

10.1.5 Pragmas and Program Units

{*AI12-0417-1*} [This subclause discusses pragmas related to compilations.] 1/5

Paragraphs 2 through 7 were moved to Annex J, "Obsolescent Features".

Post-Compilation Rules

Certain pragmas are defined to be *configuration pragmas*; they shall appear before the first compilation_unit of a compilation. [They are generally used to select a partition-wide or system-wide option.] The pragma applies to all compilation_units appearing in the compilation, unless there are none, in which case it applies to all future compilation_units compiled into the same environment. 8

Implementation Permissions

{*AI95-00212-01*} An implementation may require that configuration pragmas that select partition-wide or system-wide options be compiled when the environment contains no library_items other than those of the predefined environment. In this case, the implementation shall still accept configuration pragmas in individual compilations that confirm the initially selected partition-wide or system-wide options. 9/2

This paragraph was deleted. 10.a/5

Paragraph 10 was moved to Annex J, "Obsolescent Features".

Wording Changes from Ada 95

This paragraph was deleted.{*8652/0033*} {*AI95-00136-01*} {*AI12-0417-1*} 10.b/5

This paragraph was deleted.{*8652/0034*} {*AI95-00041-01*} {*AI12-0417-1*} 10.c/5

This paragraph was deleted.{*AI12-0417-1*} 10.d/5

{*AI95-00212-01*} The permission to place restrictions was clarified to: 10.e/2

- Ensure that it applies only to partition-wide configuration pragmas, not ones like Assertion_Policy (see 11.4.2), which can be different in different units; and 10.f/2

10.g/2 • Ensure that confirming pragmas are always allowed.

Wording Changes from Ada 2005

10.h/5 *This paragraph was deleted.*{*AI05-0132-1*} {*AI12-0417-1*}

Wording Changes from Ada 2012

10.i/5 {*AI12-0417-1*} The terms “program unit pragma” and “library unit pragma” were moved to Annex J, “Obsolescent Features” (specifically to J.15) as all of the pragmas that use these terms are now in that annex.

10.1.6 Environment-Level Visibility Rules

1 [The normal visibility rules do not apply within a parent_unit_name or a context_clause, nor within a pragma that appears at the place of a compilation unit. The special visibility rules for those contexts are given here.]

Static Semantics

2/2 {*AI95-00217-06*} {*AI95-00312-01*} Within the parent_unit_name at the beginning of an explicit library_item, and within a nonlimited_with_clause, the only declarations that are visible are those that are explicit library_items of the environment, and the only declarations that are directly visible are those that are explicit root library_items of the environment. Within a limited_with_clause, the only declarations that are visible are those that are the implicit declaration of the limited view of a library package of the environment, and the only declarations that are directly visible are those that are the implicit declaration of the limited view of a root library package.

2.a **Ramification:** In “**package** P.Q.R **is** ... **end** P.Q.R;”, this rule requires P to be a root library unit, and Q to be a library unit (because those are the things that are directly visible and visible). Note that visibility does not apply between the “**end**” and the “;”.

2.b Physically nested declarations are not visible at these places.

2.c Although Standard is visible at these places, it is impossible to name it, since it is not directly visible, and it has no parent.

2.c.1/2 {*AI95-00217-06*} Only compilation units defining limited views can be mentioned in a limited_with_clause, while only compilation units defining full views (that is, the explicit declarations) can be mentioned in a nonlimited_with_clause. This resolves the conflict inherent in having two compilation units with the same defining name.

2.d/2 *This paragraph was deleted.*{*AI95-00312-01*}

3 Within a use_clause or pragma that is within a context_clause, each library_item mentioned in a previous with_clause of the same context_clause is visible, and each root library_item so mentioned is directly visible. In addition, within such a use_clause, if a given declaration is visible or directly visible, each declaration that occurs immediately within the given declaration's visible part is also visible. No other declarations are visible or directly visible.

3.a **Discussion:** Note the word “same”. For example, if a with_clause on a declaration mentions X, this does not make X visible in use_clauses and pragmas that are on the body. The reason for this rule is the one-pass context_clauses Language Design Principle.

3.b Note that the second part of the rule does not mention pragmas.

4 Within the parent_unit_name of a subunit, library_items are visible as they are in the parent_unit_name of a library_item; in addition, the declaration corresponding to each body_stub in the environment is also visible.

4.a **Ramification:** For a subprogram without a separate subprogram_declaration, the body_stub itself is the declaration.

5 Within a pragma that appears at the place of a compilation unit, the immediately preceding library_item and each of its ancestors is visible. The ancestor root library_item is directly visible.

{*AI95-00312-01*} Notwithstanding the rules of 4.1.3, an expanded name in a with_clause, a pragma in a context_clause, or a pragma that appears at the place of a compilation unit may consist of a prefix that denotes a generic package and a selector_name that denotes a child of that generic package. [(The child is necessarily a generic unit; see 10.1.1.)] 6/2

Reason: This rule allows **with** A.B; and **pragma** Elaborate(A.B); where A is a generic library package and B is one of its (generic) children. This is necessary because it is not normally legal to use an expanded name to reach inside a generic package. 6.a/2

Wording Changes from Ada 83

The special visibility rules that apply within a parent_unit_name or a context_clause, and within a pragma that appears at the place of a compilation_unit are clarified. 6.b

Note that a context_clause is not part of any declarative region. 6.c

We considered making the visibility rules within parent_unit_names and context_clauses follow from the context of compilation. However, this attempt failed for various reasons. For example, it would require use_clauses in context_clauses to be within the declarative region of Standard, which sounds suspiciously like a kludge. And we would still need a special rule to prevent seeing things (in our own context_clause) that were with-ed by our parent, etc. 6.d

Wording Changes from Ada 95

{*AI95-00217-06*} Added separate visibility rules for limited_with_clauses; the existing rules apply only to nonlimited_with_clauses. 6.e/2

{*AI95-00312-01*} Clarified that the name of a generic child unit may appear in a pragma in a context_clause. 6.f/2

10.2 Program Execution

An Ada *program* consists of a set of *partitions*[, which can execute in parallel with one another, possibly in a separate address space, and possibly on a separate computer.] 1

Post-Compilation Rules

{*AI12-0439-1*} {*AI12-0448-1*} A partition is a program or part of a program that can be invoked from outside the Ada implementation. [For example, on many systems, a partition can be an executable file generated by the system linker.] The user can *explicitly assign* library units to a partition. The assignment is done in an implementation-defined manner. The compilation units included in a partition are those of the explicitly assigned library units, as well as other compilation units *needed by* those library units. The compilation units needed by a given compilation unit (the *needed compilation units*) are determined as follows (unless specified otherwise via an implementation-defined pragma, or by some other implementation-defined means): 2/5

Discussion: From a run-time point of view, an Ada 95 partition is identical to an Ada 83 program — implementations were always allowed to provide inter-program communication mechanisms. The additional semantics of partitions is that interfaces between them can be defined to obey normal language rules (as is done in Annex E, “Distributed Systems”), whereas interfaces between separate programs had no particular semantics. 2.a

Implementation defined: The manner of explicitly assigning library units to a partition. 2.b

Implementation defined: The implementation-defined means, if any, of specifying which compilation units are needed by a given compilation unit. 2.c

Discussion: There are no pragmas that “specify otherwise” defined by the core language. However, an implementation is allowed to provide such pragmas, and in fact Annex E, “Distributed Systems” defines some pragmas whose semantics includes reducing the set of compilation units described here. 2.d

Term entry: needed compilation unit — compilation unit that is necessary to produce an executable partition, because some entity declared or defined within the unit is used elsewhere in the partition 2.e/5

- {*AI12-0448-1*} A compilation unit is a needed compilation unit of itself; 3/5

4/5 • {*AI12-0448-1*} If a compilation unit is among the needed compilation units, then so are any compilation units upon which it depends semantically;

5/5 • {*AI12-0448-1*} If a library_unit_declaration is among the needed compilation units, then so is any corresponding library_unit_body;

6/5 • {*AI95-00217-06*} {*AI12-0448-1*} If a compilation unit with stubs is among the needed compilation units, then so are any corresponding subunits;

6.a **Discussion:** Note that in the environment, the stubs are replaced with the corresponding proper_bodies.

6.1/5 • {*AI95-00217-06*} {*AI12-0448-1*} If the (implicit) declaration of the limited view of a library package is among the needed compilation units, then so is the explicit declaration of the library package.

6.b **Discussion:** Note that a child unit is not included just because its parent is included — to include a child, mention it in a with_clause.

6.c/2 {*AI95-00217-06*} A package is included in a partition even if the only reference to it is in a limited_with_clause. While this isn't strictly necessary (no objects of types imported from such a unit can be created), it ensures that all incomplete types are eventually completed, and is the least surprising option.

7 The user can optionally designate (in an implementation-defined manner) one subprogram as the *main subprogram* for the partition. A main subprogram, if specified, shall be a subprogram.

7.a **Discussion:** This may seem superfluous, since it follows from the definition. But we would like to have every error message that might be generated (before run time) by an implementation correspond to some explicitly stated “shall” rule.

7.b Of course, this does not mean that the “shall” rules correspond one-to-one with an implementation's error messages. For example, the rule that says overload resolution “shall” succeed in producing a single interpretation would correspond to many error messages in a good implementation — the implementation would want to explain to the user exactly why overload resolution failed. This is especially true for the syntax rules — they are considered part of overload resolution, but in most cases, one would expect an error message based on the particular syntax rule that was violated.

7.c **Implementation defined:** The manner of designating the main subprogram of a partition.

7.d **Ramification:** An implementation cannot require the user to specify, say, all of the library units to be included. It has to support, for example, perhaps the most typical case, where the user specifies just one library unit, the main program. The implementation has to do the work of tracking down all the other ones.

8 Each partition has an anonymous *environment task*[, which is an implicit outermost task whose execution elaborates the library_items of the environment declarative_part, and then calls the main subprogram, if there is one. A partition's execution is that of its tasks.]

8.a **Ramification:** An environment task has no master; all nonenvironment tasks have masters.

8.b An implementation is allowed to support multiple concurrent executions of the same partition.

9/5 {*AI12-0448-1*} [The order of elaboration of library units is determined primarily by the *elaboration dependences*.] There is an elaboration dependence of a given library_item upon another if the given library_item or any of its subunits depends semantically on the other library_item. In addition, if a given library_item or any of its subunits has a pragma Elaborate or Elaborate_All that names another library unit, then there is an elaboration dependence of the given library_item upon the body of the other library unit, and, for Elaborate_All only, upon each library_item that is a needed compilation unit of the declaration of the other library unit.

9.a.1/2 **Discussion:** {*8652/0107*} {*AI95-00180-01*} {*AI95-00256-01*} “Mentions” was used informally in the above rule; it was not intended to refer to the definition of *mentions* in 10.1.2. It was changed to “names” to make this clear.

9.a See above for a definition of which library_items are “needed by” a given declaration.

9.b/5 {*AI12-0417-1*} Note that elaboration dependences are among library_items, whereas the other two forms of dependence are among compilation units. Note that elaboration dependence includes semantic dependence. It's a little bit sad that the Elaborate_Body aspect can't be folded into this mechanism. It follows from the definition that the elaboration dependence relationship is transitive. Note that the wording of the rule does not need to take into account a

semantic dependence of a library_item or one of its subunits upon a subunit of a different library unit, because that can never happen.

The environment task for a partition has the following structure: 10

```
task Environment_Task;                                                    11
task body Environment_Task is                                             12
   ... (1) -- The environment declarative_part
           -- (that is, the sequence of library_items) goes here.
begin
   ... (2) -- Call the main subprogram, if there is one.
end Environment_Task;
```

Ramification: The name of the environment task is written in italics here to indicate that this task is anonymous. 12.a

Discussion: The model is different for a "passive partition" (see E.1). Either there is no environment task, or its sequence_of_statements is an infinite loop rather than a call on a main subprogram. 12.b

The environment declarative_part at (1) is a sequence of declarative_items consisting of copies of the library_items included in the partition[. The order of elaboration of library_items is the order in which they appear in the environment declarative_part]: 13

- The order of all included library_items is such that there are no forward elaboration dependences. 14

  Ramification: This rule is written so that if a library_item depends on itself, we don't require it to be elaborated before itself. See AI83-00113/12. This can happen only in pathological circumstances. For example, if a library subprogram_body has no corresponding subprogram_declaration, and one of the subunits of the subprogram_body mentions the subprogram_body in a with_clause, the subprogram_body will depend on itself. For another example, if a library_unit_body applies a pragma Elaborate_All to its own declaration, then the library_unit_body will depend on itself. 14.a

- {*AI05-0229-1*} {*AI12-0417-1*} Any included library_unit_declaration for which aspect Elaborate_Body is True is immediately followed by its library_unit_body, if included. 15/5

  Discussion: This implies that the body of such a library unit shall not "with" any of its own children, or anything else that depends semantically upon the declaration of the library unit. 15.a

- All library_items declared pure occur before any that are not declared pure. 16

- All preelaborated library_items occur before any that are not preelaborated. 17

  Discussion: Normally, if two partitions contain the same compilation unit, they each contain a separate *copy* of that compilation unit. See Annex E, "Distributed Systems" for cases where two partitions share the same copy of something. 17.a

  There is no requirement that the main subprogram be elaborated last. In fact, it is possible to write a partition in which the main subprogram cannot be elaborated last. 17.b

  Ramification: This declarative_part has the properties required of all environments (see 10.1.4). However, the environment declarative_part of a partition will typically contain fewer compilation units than the environment declarative_part used at compile time — only the "needed" ones are included in the partition. 17.c

There shall be a total order of the library_items that obeys the above rules. The order is otherwise implementation defined. 18

Discussion: {*AI12-0417-1*} The only way to violate this rule is to have Elaborate or Elaborate_All pragmas or Elaborate_Body aspects that cause circular ordering requirements, thus preventing an order that has no forward elaboration dependences. 18.a/5

Implementation defined: The order of elaboration of library_items. 18.b

To be honest: {*AI12-0005-1*} Notwithstanding what the RM says elsewhere, each rule that requires a declaration to have a corresponding completion is considered to be a Post-Compilation Rule when the declaration is that of a library unit. 18.c/5

Discussion: Such rules may be checked at "link time", for example. Rules requiring the completion to have certain properties, on the other hand, are checked at compile time of the completion. 18.d

The full expanded names of the library units and subunits included in a given partition shall be distinct. 19

Reason: This is a Post-Compilation Rule because making it a Legality Rule would violate the Language Design Principle labeled "legality determinable via semantic dependences". 19.a

20 The sequence_of_statements of the environment task (see (2) above) consists of either:

21 • A call to the main subprogram, if the partition has one. If the main subprogram has parameters, they are passed; where the actuals come from is implementation defined. What happens to the result of a main function is also implementation defined.

21.a **Implementation defined:** Parameter passing and function return for the main subprogram.

22 or:

23 • A null_statement, if there is no main subprogram.

23.a **Discussion:** For a passive partition, either there is no environment task, or its sequence_of_statements is an infinite loop. See E.1.

24/5 {*AI12-0439-1*} The mechanisms for building and running partitions are implementation defined. [These can be combined into one operation, as, for example, in dynamic linking, or "load-and-go" systems.]

24.a **Implementation defined:** The mechanisms for building and running partitions.

Dynamic Semantics

25 The execution of a program consists of the execution of a set of partitions. Further details are implementation defined. The execution of a partition starts with the execution of its environment task, ends when the environment task terminates, and includes the executions of all tasks of the partition. [The execution of the (implicit) task_body of the environment task acts as a master for all other tasks created as part of the execution of the partition. When the environment task completes (normally or abnormally), it waits for the termination of all such tasks, and then finalizes any remaining objects of the partition.]

25.a **Ramification:** The "further details" mentioned above include, for example, program termination — it is implementation defined. There is no need to define it here; it's entirely up to the implementation whether it wants to consider the program as a whole to exist beyond the existence of individual partitions.

25.b **Implementation defined:** The details of program execution, including program termination.

25.c **To be honest:** The execution of the partition terminates (normally or abnormally) when the environment task terminates (normally or abnormally, respectively).

Bounded (Run-Time) Errors

26 Once the environment task has awaited the termination of all other tasks of the partition, any further attempt to create a task (during finalization) is a bounded error, and may result in the raising of Program_Error either upon creation or activation of the task. If such a task is activated, it is not specified whether the task is awaited prior to termination of the environment task.

Implementation Requirements

27 The implementation shall ensure that all compilation units included in a partition are consistent with one another, and are legal according to the rules of the language.

27.a **Discussion:** The consistency requirement implies that a partition cannot contain two versions of the same compilation unit. That is, a partition cannot contain two different library units with the same full expanded name, nor two different bodies for the same program unit. For example, suppose we compile the following:

27.b
```
package A is -- Version 1.
    ...
end A;
```

27.c
```
with A;
package B is
end B;
```

27.d
```
package A is -- Version 2.
    ...
end A;
```

27.e
```
with A;
package C is
end C;
```

It would be wrong for a partition containing B and C to contain both versions of A. Typically, the implementation would require the use of Version 2 of A, which might require the recompilation of B. Alternatively, the implementation might automatically recompile B when the partition is built. A third alternative would be an incremental compiler that, when Version 2 of A is compiled, automatically patches the object code for B to reflect the changes to A (if there are any relevant changes — there might not be any). 27.f

An implementation that supported fancy version management might allow the use of Version 1 in some circumstances. In no case can the implementation allow the use of both versions in the same partition (unless, of course, it can prove that the two versions are semantically identical). 27.g

The core language says nothing about inter-partition consistency; see also Annex E, "Distributed Systems". 27.h

Implementation Permissions

{*AI05-0299-1*} The kind of partition described in this subclause is known as an *active* partition. An implementation is allowed to support other kinds of partitions, with implementation-defined semantics. 28/3

Implementation defined: The semantics of any nonactive partitions supported by the implementation. 28.a

Discussion: Annex E, "Distributed Systems" defines the concept of passive partitions; they may be thought of as a partition without an environment task, or as one with a particularly simple form of environment task, having an infinite loop rather than a call on a main subprogram as its sequence_of_statements. 28.b

An implementation may restrict the kinds of subprograms it supports as main subprograms. However, an implementation is required to support all main subprograms that are public parameterless library procedures. 29

Ramification: The implementation is required to support main subprograms that are procedures declared by generic_instantiations, as well as those that are children of library units other than Standard. Generic units are, of course, not allowed to be main subprograms, since they are not subprograms. 29.a

Note that renamings are irrelevant to this rule. This rules says which subprograms (not views) have to be supported. The implementation can choose any way it wants for the user to indicate which subprogram should be the main subprogram. An implementation might allow any name of any view, including those declared by renamings. Another implementation might require it to be the original name. Another implementation still might use the name of the source file or some such thing. 29.b

If the environment task completes abnormally, the implementation may abort any dependent tasks. 30

Reason: If the implementation does not take advantage of this permission, the normal action takes place — the environment task awaits those tasks. 30.a

The possibility of aborting them is not shown in the *Environment_Task* code above, because there is nowhere to put an exception_handler that can handle exceptions raised in both the environment declarative_part and the main subprogram, such that the dependent tasks can be aborted. If we put an exception_handler in the body of the environment task, then it won't handle exceptions that occur during elaboration of the environment declarative_part. If we were to move those things into a nested block_statement, with the exception_handler outside that, then the block_statement would await the library tasks we are trying to abort. 30.b

Furthermore, this is merely a permission, and is not fundamental to the model, so it is probably better to state it separately anyway. 30.c

Note that implementations (and tools like debuggers) can have modes that provide other behaviors in addition. 30.d

NOTE 1 {*AI12-0440-1*} An implementation can provide inter-partition communication mechanism(s) via special packages and pragmas. Standard pragmas for distribution and methods for specifying inter-partition communication are defined in Annex E, "Distributed Systems". If no such mechanisms are provided, then each partition is isolated from all others, and behaves as a program in and of itself. 31/5

Ramification: Not providing such mechanisms is equivalent to disallowing multi-partition programs. 31.a

An implementation may provide mechanisms to facilitate checking the consistency of library units elaborated in different partitions; Annex E, "Distributed Systems" does so. 31.b

NOTE 2 {*AI12-0440-1*} Partitions are not required to run in separate address spaces. For example, an implementation can support dynamic linking via the partition concept. 32/5

NOTE 3 {*AI12-0417-1*} {*AI12-0449-1*} An order of elaboration of library_items that is consistent with the partial ordering defined above does not always ensure that each library_unit_body is elaborated before any other compilation unit whose elaboration necessitates that the library_unit_body be already elaborated. (In particular, there is no requirement that the body of a library unit be elaborated as soon as possible after the library_unit_declaration is elaborated, unless the pragmas or aspects in 10.2.1 are used.) 33/5

34/5 NOTE 4 {*AI12-0442-1*} A partition (active or otherwise) does not necessarily have a main subprogram. In such a case, all the work done by the partition would be done by elaboration of various library_items, and by tasks created by that elaboration. Passive partitions, which cannot have main subprograms, are defined in Annex E, “Distributed Systems”.

34.a **Ramification:** The environment task is the outermost semantic level defined by the language.

34.b Standard has no private part. This prevents strange implementation-dependences involving private children of Standard having visibility upon Standard's private part. It doesn't matter where the body of Standard appears in the environment, since it doesn't do anything. See Annex A, “Predefined Language Environment”.

34.c Note that elaboration dependence is carefully defined in such a way that if (say) the body of something doesn't exist yet, then there is no elaboration dependence upon the nonexistent body. (This follows from the fact that “needed by” is defined that way, and the elaboration dependences caused by a pragma Elaborate or Elaborate_All are defined in terms of “needed by”.) This property allows us to use the environment concept both at compile time and at partition-construction time/run time.

Extensions to Ada 83

34.d The concept of partitions is new to Ada 95.

34.e A main subprogram is now optional. The language-defined restrictions on main subprograms are relaxed.

Wording Changes from Ada 83

34.f Ada 95 uses the term “main subprogram” instead of Ada 83's “main program” (which was inherited from Pascal). This is done to avoid confusion — a main subprogram is a subprogram, not a program. The program as a whole is an entirely different thing.

Wording Changes from Ada 95

34.g/2 {*AI95-00256-01*} The mistaken use of “mentions” in the elaboration dependence rule was fixed.

34.h/5 {*AI95-00217-06*} {*AI12-0448-1*} The *needed* relationship was extended to include limited views.

10.2.1 Elaboration Control

1/5 {*AI12-0417-1*} [This subclause defines aspects and pragmas that help control the elaboration order of library_items.]

Language Design Principles

1.a The rules governing preelaboration are designed to allow it to be done largely by bulk initialization of statically allocated storage from information in a “load module” created by a linker. Some implementations may require run-time code to be executed in some cases, but we consider these cases rare enough that we need not further complicate the rules.

1.b It is important that programs be able to declare data structures that are link-time initialized with aggregates, string_literals, and concatenations thereof. It is important to be able to write link-time evaluated expressions involving the First, Last, and Length attributes of such data structures (including variables), because they might be initialized with positional aggregates or string_literals, and we don't want the user to have to count the elements. There is no corresponding need for accessing discriminants, since they can be initialized with a static constant, and then the constant can be referred to elsewhere. It is important to allow link-time initialized data structures involving discriminant-dependent components. It is important to be able to write link-time evaluated expressions involving pointers (both access values and addresses) to the above-mentioned data structures.

1.c The rules also ensure that no Elaboration_Check need be performed for calls on library-level subprograms declared within a preelaborated package. This is true also of the Elaboration_Check on task activation for library level task types declared in a preelaborated package. However, it is not true of the Elaboration_Check on instantiations.

1.d A static expression should never prevent a library unit from being preelaborable.

Paragraphs 2 through 4 were moved to Annex J, “Obsolescent Features”.

Legality Rules

5 An elaborable construct is preelaborable unless its elaboration performs any of the following actions:

5.a **Ramification:** A *preelaborable* construct can be elaborated without using any information that is available only at run time. Note that we don't try to prevent exceptions in preelaborable constructs; if the implementation wishes to generate code to raise an exception, that's OK.

Because there is no flow of control and there are no calls (other than to predefined subprograms), these run-time properties can actually be detected at compile time. This is necessary in order to require compile-time enforcement of the rules. 5.b

- The execution of a statement other than a null_statement. 6

  Ramification: A preelaborable construct can contain labels and null_statements. 6.a

- {*AI12-0175-1*} A call to a subprogram other than: 7/5
  - a static function; 7.1/5
  - an instance of Unchecked_Conversion (see 13.9); 7.2/5
  - a function declared in System.Storage_Elements (see 13.7.1); or 7.3/5
  - the functions To_Pointer and To_Address declared in an instance of System.Address_to_Access_Conversions (see 13.7.2). 7.4/5

    Ramification: {*AI12-0175-1*} The parameters of any such function have to pass the preelaborability rules, so they typically have to be static expressions. The extra allowed functions are all forms of conversion that the compiler understands, so there should be little implementation burden. Note that such a call might raise an exception; preelaborable is not the same as elaborable with no code. 7.a/5

- The evaluation of a primary that is a name of an object, unless the name is a static expression, or statically denotes a discriminant of an enclosing type. 8

  Ramification: One can evaluate such a name, but not as a primary. For example, one can evaluate an attribute of the object. One can evaluate an attribute_reference, so long as it does not denote an object, and its prefix does not disobey any of these rules. For example, Obj'Access, Obj'Unchecked_Access, and Obj'Address are generally legal in preelaborated library units. 8.a

- {*AI95-00161-01*} {*AI05-0028-1*} The creation of an object [(including a component)] that is initialized by default, if its type does not have preelaborable initialization. Similarly, the evaluation of an extension_aggregate with an ancestor subtype_mark denoting a subtype of such a type. 9/3

  Ramification: One can declare these kinds of types, but one cannot create objects of those types. 9.a

  It is also nonpreelaborable to create an object if that will cause the evaluation of a default expression that will call a user-defined function. This follows from the rule above forbidding nonnull statements. 9.b

  This paragraph was deleted.{*AI95-00161-01*} 9.c/2

- {*AI12-0232-1*} The elaboration of any elaborable construct that is not preelaborable. 9.1/5

{*AI12-0232-1*} A generic declaration is preelaborable unless every instance would perform one of the above actions. 9.2/5

Ramification: {*AI12-0232-1*} {*AI12-0417-1*} A generic declaration is preelaborable unless there is no instance that could be declared preelaborated. For instance, a generic package declaration that directly contains a variable initialized by a non-static function that is not a formal function is not preelaborable (and thus would be illegal if the Preelaborate aspect were applied to it). 9.d/5

{*AI95-00403-01*} A generic body is preelaborable only if elaboration of a corresponding instance body would not perform any such actions, presuming that: 10/2

- {*AI95-00403-01*} {*AI05-0028-1*} {*AI12-0417-1*} the actual for each discriminated formal derived type, formal private type, or formal private extension declared within the formal part of the generic unit is a type that does not have preelaborable initialization, unless the Preelaborable_Initialization aspect was specified for the formal type; 10.1/5
- {*AI95-00403-01*} the actual for each formal type is nonstatic; 10.2/2
- {*AI95-00403-01*} the actual for each formal object is nonstatic; and 10.3/2
- {*AI95-00403-01*} the actual for each formal subprogram is a user-defined subprogram. 10.4/2

  Discussion: {*AI95-00403-01*} This is an “assume-the-worst” rule. The elaboration of a generic unit doesn't perform any of the actions listed above, because its sole effect is to establish that the generic can from now on be instantiated. 10.a.1/2

So the elaboration of the generic itself is not the interesting part when it comes to preelaboration rules. The interesting part is what happens when you elaborate "any instantiation" of the generic. For instance, declaring an object of a limited formal private type might well start tasks, call functions, and do all sorts of nonpreelaborable things. We prevent these situations by assuming that the actual parameters are as badly behaved as possible.

10.a **Reason:** Without this rule about generics, we would have to forbid instantiations in preelaborated library units, which would significantly reduce their usefulness.

11/5 {*8652/0035*} {*AI95-00002-01*} {*AI05-0034-1*} {*AI05-0243-1*} {*AI12-0417-1*} When the library unit aspect (see 13.1.1) Preelaborate of a program unit is True, the unit is said to be *preelaborated*. When the Preelaborate aspect is specified True for a library unit, all compilation units of the library unit are preelaborated. The declaration and body of a preelaborated library unit, and all subunits that are elaborated as part of elaborating the library unit, shall be preelaborable. All compilation units of a preelaborated library unit shall depend semantically only on declared pure or preelaborated library_items. In addition to the places where Legality Rules normally apply (see 12.3), these rules also apply in the private part of an instance of a generic unit. [If a library unit is preelaborated, then its declaration, if any, and body, if any, are elaborated prior to all nonpreelaborated library_items of the partition.]

11.a **Ramification:** In a generic body, we assume the worst about formal private types and extensions.

11.a.1/1 {*8652/0035*} {*AI95-00002-01*} Subunits of a preelaborated subprogram unit do not need to be preelaborable. This is needed in order to be consistent with units nested in a subprogram body, which do not need to be preelaborable even if the subprogram is preelaborated. However, such subunits cannot depend semantically on nonpreelaborated units, which is also consistent with nested units.

11.a.2/5 {*AI12-0417-1*} If a unit is not preelaborated, the value of the Preelaborate aspect for that unit is False.

11.b/3 **Aspect Description for Preelaborate:** Code execution during elaboration is avoided for a given package.

11.c/5 **Discussion:** {*AI12-0417-1*} Rules for specifying a library unit aspect (like Preelaborate) are found in 13.1.1.

11.1/5 {*AI95-00161-01*} {*AI12-0409-1*} The following rules specify which entities have *preelaborable initialization*, namely that the Preelaborable_Initialization aspect of the entity is True:

11.2/5 - {*AI05-0028-1*} {*AI12-0409-1*} {*AI12-0444-1*} The partial view of a private type or private extension, a protected type without entry_declarations, a generic formal private type, or a generic formal derived type, has preelaborable initialization if and only if the Preelaborable_Initialization aspect has been specified True for them. [A protected type with entry_declarations or a task type never has preelaborable initialization.] The Preelaborable_Initialization aspect of a partial view of a type may be specified as False, even if the full view of the type has preelaborable initialization. Similarly, a generic formal type may be specified with Preelaborable_Initialization False, even if the actual type in an instance has preelaborable initialization.

11.3/2 - A component (including a discriminant) of a record or protected type has preelaborable initialization if its declaration includes a default_expression whose execution does not perform any actions prohibited in preelaborable constructs as described above, or if its declaration does not include a default expression and its type has preelaborable initialization.

11.4/3 - {*AI05-0028-1*} {*AI05-0221-1*} A derived type has preelaborable initialization if its parent type has preelaborable initialization and if the noninherited components all have preelaborable initialization. However, a controlled type with an Initialize procedure that is not a null procedure does not have preelaborable initialization.

11.5/2 - {*AI95-00161-01*} {*AI95-00345-01*} A view of a type has preelaborable initialization if it is an elementary type, an array type whose component type has preelaborable initialization, a record type whose components all have preelaborable initialization, or an interface type.

11.6/5 {*AI95-00161-01*} {*AI12-0409-1*} The following attribute is defined for a nonformal composite subtype S declared within the visible part of a package or a generic package, or a generic formal private subtype or formal derived subtype:

S'Preelaborable_Initialization 11.7/5

{*AI12-0409-1*} This attribute is of Boolean type, and its value reflects whether the type of S has preelaborable initialization. The value of this attribute, the type-related Preelaborable_Initialization aspect, may be specified for any type for which the attribute is defined. The value shall be specified by a static expression, unless the type is not a formal type but is nevertheless declared within a generic package. In this latter case, the value may also be specified by references to the Preelaborable_Initialization attribute of one or more formal types visible at the point of the declaration of the composite type, conjoined with **and**.

Ramification: {*AI12-0409-1*} "Formal types visible at the point of the declaration" includes all visible formal types, including those that might have been declared in formal packages or in child packages. 11.d/5

Aspect Description for Preelaborable_Initialization: Declares that a type has preelaborable initialization. 11.e/5

{*AI95-00161-01*} {*AI95-00345-01*} {*AI05-0028-1*} {*AI12-0409-1*} If the Preelaborable_Initialization aspect is specified True for a private type or a private extension, the full view of the type shall have preelaborable initialization. If the aspect is specified True for a protected type, the protected type shall not have entries, and each component of the protected type shall have preelaborable initialization. If the aspect is specified True for a generic formal type, then in a generic_instantiation the corresponding actual type shall have preelaborable initialization. If the aspect definition includes one or more Preelaborable_Initialization attribute_references, then the full view of the type shall have preelaborable initialization presuming the types mentioned in the prefixes of the attribute_references all have preelaborable initialization. For any other composite type, the aspect shall be specified statically True or False only if it is confirming. In addition to the places where Legality Rules normally apply (see 12.3), these rules apply also in the private part of an instance of a generic unit. 11.8/5

Reason: {*AI05-0028-1*} {*AI12-0409-1*} The reason why we need to be allowed to specify the aspect for private types, private extensions, and protected types is fairly clear: the properties of the full view determine whether the type has preelaborable initialization or not; in order to preserve privacy we need a way to express on the partial view that the full view is well-behaved. The reason why we need to be allowed to specify the aspect for other composite types is more subtle: a nonnull override for Initialize might occur in the private part, even for a nonprivate type; in order to preserve privacy, we need a way to express on a type declared in a visible part that the private part does not contain any nasty override of Initialize. 11.f/5

Ramification: {*AI12-0409-1*} Not only do protected types with entry_declarations and task types not have preelaborable initialization, but they cannot have Preelaborable_Initialization aspect specified True for them. 11.g/5

Implementation Advice

In an implementation, a type declared in a preelaborated package should have the same representation in every elaboration of a given version of the package, whether the elaborations occur in distinct executions of the same program, or in executions of distinct programs or partitions that include the given version. 12

Implementation Advice: A type declared in a preelaborated package should have the same representation in every elaboration of a given version of the package. 12.a/2

Paragraphs 13 through 15 were moved to Annex J, "Obsolescent Features".

Static Semantics

{*AI95-00366-01*} {*AI05-0035-1*} {*AI12-0232-1*} A *pure* program unit is a preelaborable program unit whose elaboration does not perform any of the following actions: 15.1/5

- the elaboration of a variable declaration; 15.2/2
- the evaluation of an allocator of an access-to-variable type; for the purposes of this rule, the partial view of a type is presumed to have nonvisible components whose default initialization evaluates such an allocator; 15.3/2

Reason: {*AI05-0004-1*} Such an allocator would provide a backdoor way to get a global variable into a pure unit, so it is prohibited. Most such allocators are illegal anyway, as their type is required to have Storage_Size = 0 (see the next two rules). But access parameters and access discriminants don't necessarily disallow allocators. However, a call is 15.a.1/3

also illegal here (by the preelaboration rules), so access parameters cannot cause trouble. So this rule is really about prohibiting allocators in discriminant constraints:

15.a.2/3
```
type Rec (Acc : access Integer) is record
    C : Character;
end record;
```

15.a.3/3
```
Not_Const : constant Rec (Acc => new Integer'(2)); -- Illegal in a pure unit.
```

15.a/5 {*AI05-0004-1*} {*AI12-0417-1*} The second half of the rule is needed because aggregates can specify the default initialization of a private type or extension using <> or the ancestor subtype of an extension aggregate. The subtype of a component could use an allocator to initialize an access discriminant; the type still could have the Preelaborable_Initialization aspect specified. Ada 95 did not allow such private types to have preelaborable initialization, so such a default initialization could not have occurred. Thus this rule is not incompatible with Ada 95.

15.4/3 • {*AI05-0035-1*} the elaboration of the declaration of a nonderived named access-to-variable type unless the Storage_Size of the type has been specified by a static expression with value zero or is defined by the language to be zero;

15.b/2 **Discussion:** A remote access-to-class-wide type (see E.2.2) has its Storage_Size defined to be zero.

15.c/2 **Reason:** {*AI95-00366-01*} We disallow most named access-to-object types because an allocator has a side effect; the pool constitutes variable data. We allow access-to-subprogram types because they don't have allocators. We even allow named access-to-object types if they have an empty predefined pool (they can't have a user-defined pool as System.Storage_Pools is not pure). In this case, most attempts to use an allocator are illegal, and any others (in a generic body) will raise Storage_Error.

15.5/5 • {*AI05-0035-1*} {*AI12-0232-1*} the elaboration of the declaration of a nonderived named access-to-constant type for which the Storage_Size has been specified by an expression other than a static expression with value zero;

15.d/2 **Discussion:** We allow access-to-constant types so long as there is no user-specified nonzero Storage_Size; if there were a user-specified nonzero Storage_Size restricting the size of the storage pool, allocators would be problematic since the package is supposedly ‘stateless’, and the allocated size count for the storage pool would represent state.

15.6/5 • {*AI12-0232-1*} the elaboration of any program unit that is not pure.

15.7/5 {*AI12-0232-1*} A generic declaration is pure unless every instance would perform one of the above actions.

15.d.1/5 **Ramification:** {*AI12-0232-1*} {*AI12-0417-1*} A generic declaration is pure unless there is no instance that could be declared pure. For instance, a generic package declaration that directly contains a variable declaration is not pure (and thus would be illegal if aspect Pure is specified for it).

15.8/5 {*AI05-0035-1*} {*AI12-0232-1*} A generic body is pure only if elaboration of a corresponding instance body would not perform any such actions presuming any composite formal types have nonvisible components whose default initialization evaluates an allocator of an access-to-variable type.

15.9/5 {*AI95-00366-01*} {*AI12-0232-1*} The Storage_Size for an anonymous access-to-variable type declared at library level in a library unit that is declared pure is defined to be zero.

15.e/2 **Ramification:** This makes allocators illegal for such types (see 4.8), making a storage pool unnecessary for these types. A storage pool would represent state.

15.f/2 Note that access discriminants and access parameters are never library-level, even when they are declared in a type or subprogram declared at library-level. That's because they have their own special accessibility rules (see 3.10.2).

Legality Rules

16/2 *This paragraph was deleted.*{*AI95-00366-01*}

17/5 {*AI95-00366-01*} {*AI05-0034-1*} {*AI05-0035-1*} {*AI05-0243-1*} {*AI12-0417-1*} When the library unit aspect Pure of a program unit is True, the unit is said to be *declared pure*. When the Pure aspect is specified True for a library unit, all compilation units of the library unit are declared pure. In addition, the limited view of any library package is declared pure. The declaration and body of a declared pure library unit, and all subunits that are elaborated as part of elaborating the library unit, shall be pure. All compilation units of a declared pure library unit shall depend semantically only on declared pure

library_items. In addition to the places where Legality Rules normally apply (see 12.3), these rules also apply in the private part of an instance of a generic unit. Furthermore, the full view of any partial view declared in the visible part of a declared pure library unit that has any available stream attributes shall support external streaming (see 13.13.2).

This paragraph was deleted.{*AI05-0243-1*} 17.a/3

Discussion: A declared-pure package is useful for defining types to be shared between partitions with no common address space. 17.b

Reason: Note that generic packages are not mentioned in the list of things that can contain variable declarations. Note that the Ada 95 rules for deferred constants make them allowable in library units that are declared pure; that isn't true of Ada 83's deferred constants. 17.c

Ramification: {*AI95-00366-01*} Anonymous access types are allowed. 17.d/2

{*AI05-0243-1*} A limited view is not a library unit, so any rule that starts "declared pure library unit" does not apply to a limited view. In particular, the 3rd and last sentences never apply to limited views. However, a limited view is a library_item, so rules that discuss "declared pure library_items" do include limited views. 17.d.1/3

{*AI12-0417-1*} If a unit is not declared pure, the value of the Pure aspect for that unit is False. 17.d.2/5

Reason: {*AI95-00366-01*} Ada 95 didn't allow any access types as these (including access-to-subprogram types) cause trouble for Annex E, "Distributed Systems", because such types allow access values in a shared passive partition to designate objects in an active partition, thus allowing inter-address space references. We decided to disallow such uses in the relatively rare cases where they cause problems, rather than making life harder for the majority of users. Types declared in a pure package can be used in remote operations only if they are externally streamable. That simply means that there is a means to transport values of the type; that's automatically true for nonlimited types that don't have an access part. The only tricky part about this is to avoid privacy leakage; that was handled by ensuring that any private types (and private extensions) declared in a pure package that have available stream attributes (which include all nonlimited types by definition) have to be externally streamable. 17.e/2

Aspect Description for Pure: Side effects are avoided in the subprograms of a given package. 17.f/3

Erroneous Execution

{*AI12-0076-1*} Execution is erroneous if some operation (other than the initialization or finalization of the object) modifies the value of a constant object declared at library-level in a pure package. 17.1/4

Discussion: This could be accomplished via a self-referencing pointer or via squirrelling a writable pointer to a controlled object. 17.g/4

Implementation Permissions

{*AI95-00366-01*} {*AI05-0219-1*} If a library unit is declared pure, then the implementation is permitted to omit a call on a library-level subprogram of the library unit if the results are not needed after the call. In addition, the implementation may omit a call on such a subprogram and simply reuse the results produced by an earlier call on the same subprogram, provided that none of the parameters nor any object accessible via access values from the parameters have any part that is of a type whose full type is an immutably limited type, and the addresses and values of all by-reference actual parameters, the values of all by-copy-in actual parameters, and the values of all objects accessible via access values from the parameters, are the same as they were at the earlier call. [This permission applies even if the subprogram produces other side effects when called.] 18/3

Discussion: {*AI95-00366-01*} {*AI05-0005-1*} {*AI05-0299-1*} A declared-pure library_item has no variable state. Hence, a call on one of its (nonnested) subprograms cannot normally have side effects. Side effects are still possible via dispatching calls and via indirect calls through access-to-subprogram values. Other mechanisms that might be used to modify variable state include machine code insertions, imported subprograms, and unchecked conversion to an access type declared within the subprogram; this list is not exhaustive. Thus, the permissions described in this subclause may apply to a subprogram whose execution has side effects. The compiler may omit a call to such a subprogram even if side effects exist, so the writer of such a subprogram has to keep this in mind. 18.a/3

Syntax

19/5 {*AI12-0417-1*} The following pragmas are defined with the given forms:

20 **pragma** Elaborate(*library_unit*_name{, *library_unit*_name});

21 **pragma** Elaborate_All(*library_unit*_name{, *library_unit*_name});

22/5 *This paragraph was deleted.*{*AI12-0417-1*}

23 A pragma Elaborate or Elaborate_All is only allowed within a context_clause.

23.a **Ramification:** "Within a context_clause" allows it to be the last item in the context_clause. It can't be first, because the name has to denote something mentioned earlier.

24/5 *This paragraph was deleted.*{*AI12-0417-1*}

24.a **Discussion:** Hence, a pragma Elaborate or Elaborate_All is not elaborated, not that it makes any practical difference.

24.b Note that a pragma Elaborate or Elaborate_All is neither a program unit pragma, nor a library unit pragma.

Legality Rules

25/5 {*AI05-0229-1*} {*AI12-0417-1*} If the aspect Elaborate_Body is True for a declaration, then the declaration requires a completion [(a body)].

25.1/2 {*AI95-00217-06*} The *library_unit*_name of a pragma Elaborate or Elaborate_All shall denote a nonlimited view of a library unit.

25.b/2 **Reason:** These pragmas are intended to prevent elaboration check failures. But a limited view does not make anything visible that has an elaboration check, so the pragmas cannot do anything useful. Moreover, the pragmas would probably reintroduce the circularity that the limited_with_clause was intended to break. So we make such uses illegal.

Static Semantics

26/3 {*AI05-0229-1*} [A pragma Elaborate specifies that the body of the named library unit is elaborated before the current library_item. A pragma Elaborate_All specifies that each library_item that is needed by the named library unit declaration is elaborated before the current library_item.]

26.a **Proof:** The official statement of the semantics of these pragmas is given in 10.2.

26.1/5 {*AI05-0229-1*} {*AI12-0417-1*} [If the Elaborate_Body aspect of a library unit is True, the body of the library unit is elaborated immediately after its declaration.]

26.a.1/3 **Proof:** The official statement of the semantics of this aspect is given in 10.2.

26.b/5 **Implementation Note:** {*AI12-0417-1*} The specification of the Elaborate_Body aspect simplifies the removal of unnecessary Elaboration_Checks. For a subprogram declared immediately within a library unit for which the Elaborate_Body aspect is specified as True, the only calls that can fail the Elaboration_Check are those that occur in the library unit itself, between the declaration and body of the called subprogram; if there are no such calls (which can easily be detected at compile time if there are no stubs), then no Elaboration_Checks are needed for that subprogram. The same is true for Elaboration_Checks on task activations and instantiations, and for library subprograms and generic units.

26.c **Ramification:** The fact that the unit of elaboration is the library_item means that if a subprogram_body is not a completion, it is impossible for any library_item to be elaborated between the declaration and the body of such a subprogram. Therefore, it is impossible for a call to such a subprogram to fail its Elaboration_Check.

26.d **Discussion:** The visibility rules imply that each *library_unit*_name of a pragma Elaborate or Elaborate_All has to denote a library unit mentioned by a previous with_clause of the same context_clause.

26.e/5 **Aspect Description for Elaborate_Body:** A given package will have a body, and that body is elaborated immediately after the declaration.

27/5 NOTE 1 {*AI12-0447-1*} A preelaborated library unit can have nonpreelaborable children.

27.a/1 **Ramification:** {*8652/0035*} {*AI95-00002-01*} But generally not nonpreelaborated subunits. (Nonpreelaborated subunits of subprograms are allowed as discussed above.)

28/5 NOTE 2 {*AI12-0447-1*} A library unit that is declared pure can have impure children.

Ramification: {*8652/0035*} {*AI95-00002-01*} But generally not impure subunits. (Impure subunits of subprograms are allowed as discussed above.) 28.a/1

Ramification: Pragma Elaborate is mainly for closely related library units, such as when two package bodies 'with' each other's declarations. In such cases, Elaborate_All sometimes won't work. 28.b

Extensions to Ada 83

The concepts of preelaborability and purity are new to Ada 95. The Elaborate_All, Elaborate_Body, Preelaborate, and Pure pragmas are new to Ada 95. 28.c

Pragmas Elaborate are allowed to be mixed in with the other things in the context_clause — in Ada 83, they were required to appear last. 28.d

Incompatibilities With Ada 95

{*AI95-00366-01*} The requirement that a partial view with available stream attributes be externally streamable can cause an incompatibility in rare cases. If there is a limited tagged type declared in a pure package with available attributes, and that type is used to declare a private extension in another pure package, and the full type for the private extension has a component of an explicitly limited record type, a protected type, or a type with access discriminants, then the stream attributes will have to be user-specified in the visible part of the package. That is not a requirement for Ada 95, but this combination seems very unlikely in pure packages. Note that this cannot be an incompatibility for a nonlimited type, as all of the types that are allowed in Ada 95 that would require explicitly defined stream attributes are limited (and thus cannot be used as components in a nonlimited type). 28.e/2

{*AI95-00403-01*} **Amendment Correction:** Added wording to cover missing cases for preelaborated generic units. This is incompatible as a preelaborated unit could have used a formal object to initialize a library-level object; that isn't allowed in Ada 2005. But such a unit wouldn't really be preelaborable, and Ada 95 compilers can reject such units (as this is a Binding Interpretation), so such units should be very rare. 28.f/2

Extensions to Ada 95

{*AI95-00161-01*} **Amendment Correction:** The concept of preelaborable initialization and pragma Preelaborable_Initialization are new. These allow more types of objects to be created in preelaborable units, and fix holes in the old rules. 28.g/2

{*AI95-00366-01*} Access-to-subprogram types and access-to-object types with a Storage_Size of 0 are allowed in pure units. The permission to omit calls was adjusted accordingly (which also fixes a hole in Ada 95, as access parameters are allowed, and changes in the values accessed by them must be taken into account). 28.h/2

Wording Changes from Ada 95

{*AI95-00002-01*} **Corrigendum:** The wording was changed so that subunits of a preelaborated subprogram are also preelaborated. 28.i/2

{*AI95-00217-06*} Disallowed pragma Elaborate and Elaborate_All for packages that are mentioned in a limited_with_clause. 28.j/2

Incompatibilities With Ada 2005

{*AI05-0028-1*} **Correction:** Corrected a serious unintended incompatibility with Ada 95 in the new preelaboration wording — explicit initialization of objects of types that don't have preelaborable initialization was not allowed. Ada 2012 switches back to the Ada 95 rule in these cases. This is unlikely to occur in practice, as it is unlikely that a compiler would have implemented the more restrictive rule (it would fail many ACATS tests if it did). 28.k/3

{*AI05-0035-1*} **Correction:** Added an assume-the-worst rule for generic bodies (else they would never be checked for purity) and added the boilerplate so that the entire generic specification is rechecked. Also fixed wording to have consistent handling for subunits for Pure and Preelaborate. An Ada 95 program could have depended on marking a generic pure that was not really pure, although this would defeat the purpose of the categorization and likely cause problems with distributed programs. 28.l/3

Extensions to Ada 2005

{*AI05-0035-1*} **Correction:** Adjusted wording so that a subunit can be pure (it is not a library_item, but it is a compilation unit). 28.m/3

{*AI05-0035-1*} **Correction:** Adjusted wording so that the rules for access types only apply to nonderived types (derived types share their storage pool with their parent, so if the parent access type is legal, so is any derived type.) 28.n/3

{*AI05-0229-1*} {*AI12-0417-1*} Elaborate_Body is now an aspect, so it can be specified by an aspect_specification 28.o/5

28.p/5 {*AI05-0243-1*} {*AI12-0417-1*} Pure and Preelaborate are now aspects, so they can be specified by an aspect_specification

Wording Changes from Ada 2005

28.q/3 {*AI05-0034-1*} **Correction:** Added wording so that a limited view is always treated as pure, no matter what categorization is used for the originating unit. This was undefined in Ada 2005.

28.r/3 {*AI05-0028-1*} {*AI05-0221-1*} **Correction:** Fixed minor issues with preelaborable initialization (PI): null Initialize procedures do not make a type non-PI; formal types with pragma PI can be assumed to have PI; formal extensions are assumed to not have PI; all composite types can have pragma PI (so that the possibility of hidden Initialize routines can be handled); added discriminants of a derived type are not considered in calculating PI.

28.s/3 {*AI05-0219-1*} **Correction:** Clarified that the implementation permission to omit pure subprogram calls does not apply if any part of the parameters or any designated object has a part that is immutably limited. The old wording just said "limited type", which can change via visibility and thus isn't appropriate for dynamic semantics permissions.

Incompatibilities With Ada 2012

28.t/5 {*AI12-0232-1*} **Correction:** Added a rule that a generic declaration is not pure if no instance could be pure (for instance, because the generic declaration would elaborates a variable.) This was legal in Ada 2012, but of course no instance could have been declared pure. A similar rule (with a similar effect) was added for preelaborable generic declarations.

Extensions to Ada 2012

28.u/5 {*AI12-0175-1*} Added some intrinsic conversion functions to those allowed to be called during the elaboration of a preelaborated unit. This is necessary to allow a portable Address aspect in a preelaborated unit, important on small embedded systems.

28.v/5 {*AI12-0409-1*} Aspect Preelaborable_Initialization is new; pragma Preelaborable_Initialization is now obsolescent.

Wording Changes from Ada 2012

28.w/4 {*AI12-0076-1*} **Corrigendum:** Explicitly stated that modifying a library-level constant in a pure package is erroneous. We don't document this as inconsistent as implementations certainly can still do whatever they were previously doing (no change is required); moreover, this case (and many more) were erroneous in Ada 2005 and before, so we're just restoring the previous semantics.

28.x/5 {*AI12-0232-1*} **Correction:** Explicitly stated that the pure and preelaborate rules are recursive; that is, they apply to the contents of nested packages and generic packages.

28.y/5 {*AI12-0417-1*} The pragmas that set aspects (Pure, Preelaborate, Elaborate_Body) are now obsolescent.

11 Exceptions

{*AI05-0299-1*} [This clause defines the facilities for dealing with errors or other exceptional situations that arise during program execution.] An *exception* represents a kind of exceptional situation; an occurrence of such a situation (at run time) is called an *exception occurrence*. [To *raise* an exception is to abandon normal program execution so as to draw attention to the fact that the corresponding situation has arisen. Performing some actions in response to the arising of an exception is called *handling* the exception.] 1/3

To be honest: ...or handling the exception occurrence. 1.a

Ramification: For example, an exception End_Error might represent error situations in which an attempt is made to read beyond end-of-file. During the execution of a partition, there might be numerous occurrences of this exception. 1.b

To be honest: {*AI12-0426-1*} When the meaning is clear from the context, we sometimes use "*occurrence*" as a shorthand for "exception occurrence". 1.c/5

Term entry: exception — kind of exceptional situation 1.d/5

Term entry: exception occurrence — run-time occurrence of an exceptional situation 1.e/5

{*AI05-0043-1*} {*AI05-0258-1*} [An exception_declaration declares a name for an exception. An exception can be raised explicitly (for example, by a raise_statement) or implicitly (for example, by the failure of a language-defined check). When an exception arises, control can be transferred to a user-provided exception_handler at the end of a handled_sequence_of_statements, or it can be propagated to a dynamically enclosing execution.] 2/3

Wording Changes from Ada 83

We are more explicit about the difference between an exception and an occurrence of an exception. This is necessary because we now have a type (Exception_Occurrence) that represents exception occurrences, so the program can manipulate them. Furthermore, we say that when an exception is propagated, it is the same occurrence that is being propagated (as opposed to a new occurrence of the same exception). The same issue applies to a re-raise statement. In order to understand these semantics, we have to make this distinction. 2.a

Wording Changes from Ada 2005

{*AI05-0043-1*} **Correction:** Generalized the introductory description of how an exception can be raised so that it does not appear to cover all of the cases. 2.b/3

11.1 Exception Declarations

An exception_declaration declares a name for an exception. 1

Syntax

{*AI05-0183-1*} exception_declaration ::= defining_identifier_list : **exception** [aspect_specification]; 2/3

Static Semantics

Each single exception_declaration declares a name for a different exception. If a generic unit includes an exception_declaration, the exception_declarations implicitly generated by different instantiations of the generic unit refer to distinct exceptions (but all have the same defining_identifier). The particular exception denoted by an exception name is determined at compilation time and is the same regardless of how many times the exception_declaration is elaborated. 3

Reason: We considered removing this requirement inside generic bodies, because it is an implementation burden for implementations that wish to share code among several instances. In the end, it was decided that it would introduce too much implementation dependence. 3.a

3.b **Ramification:** Hence, if an exception_declaration occurs in a recursive subprogram, the exception name denotes the same exception for all invocations of the recursive subprogram. The reason for this rule is that we allow an exception occurrence to propagate out of its declaration's innermost containing master; if exceptions were created by their declarations like other entities, they would presumably be destroyed upon leaving the master; we would have to do something special to prevent them from propagating to places where they no longer exist.

3.c **Ramification:** Exception identities are unique across all partitions of a program.

4 The *predefined* exceptions are the ones declared in the declaration of package Standard: Constraint_Error, Program_Error, Storage_Error, and Tasking_Error[; one of them is raised when a language-defined check fails.]

4.a **Ramification:** The exceptions declared in the language-defined package IO_Exceptions, for example, are not predefined.

Dynamic Semantics

5 The elaboration of an exception_declaration has no effect.

6/5 {*AI12-0445-1*} The execution of any construct raises Storage_Error if there is insufficient storage for that execution. The amount of storage necessary for the execution of constructs is unspecified.

6.a **Ramification:** Note that any execution whatsoever can raise Storage_Error. This allows much implementation freedom in storage management.

Examples

7 *Examples of user-defined exception declarations:*

8
```
Singular : exception;
Error    : exception;
Overflow, Underflow : exception;
```

Inconsistencies With Ada 83

8.a The exception Numeric_Error is now defined in the Obsolescent features Annex, as a rename of Constraint_Error. All checks that raise Numeric_Error in Ada 83 instead raise Constraint_Error in Ada 95. To increase upward compatibility, we also changed the rules to allow the same exception to be named more than once by a given handler. Thus, "**when** Constraint_Error | Numeric_Error =>" will remain legal in Ada 95, even though Constraint_Error and Numeric_Error now denote the same exception. However, it will not be legal to have separate handlers for Constraint_Error and Numeric_Error. This change is inconsistent in the rare case that an existing program explicitly raises Numeric_Error at a point where there is a handler for Constraint_Error; the exception will now be caught by that handler.

Wording Changes from Ada 83

8.b We explicitly define elaboration for exception_declarations.

Extensions to Ada 2005

8.c/3 {*AI05-0183-1*} An optional aspect_specification can be used in a exception_declaration. This is described in 13.1.1.

11.2 Exception Handlers

1 [The response to one or more exceptions is specified by an exception_handler.]

Syntax

2
```
handled_sequence_of_statements ::=
    sequence_of_statements
  [exception
    exception_handler
    {exception_handler}]
```

3/5 {*AI12-0212-1*} exception_handler ::=
when [choice_parameter_specification:] exception_choice {'|' exception_choice} =>

sequence_of_statements

choice_parameter_specification ::= defining_identifier 4

exception_choice ::= *exception*_name | **others** 5

To be honest: "*Handler*" is an abbreviation for "exception_handler". 5.a

{*AI05-0299-1*} Within this clause, we sometimes abbreviate "exception_choice" to "*choice*". 5.b/3

Legality Rules

{*AI12-0022-1*} An *exception*_name of an exception_choice shall denote an exception. 5.1/4

A choice with an *exception*_name *covers* the named exception. A choice with **others** covers all exceptions not named by previous choices of the same handled_sequence_of_statements. Two choices in different exception_handlers of the same handled_sequence_of_statements shall not cover the same exception. 6

Ramification: Two exception_choices of the same exception_handler may cover the same exception. For example, given two renaming declarations in separate packages for the same exception, one may nevertheless write, for example, "**when** Ada.Text_IO.Data_Error | My_Seq_IO.Data_Error =>". 6.a

An **others** choice even covers exceptions that are not visible at the place of the handler. Since exception raising is a dynamic activity, it is entirely possible for an **others** handler to handle an exception that it could not have named. 6.b

A choice with **others** is allowed only for the last handler of a handled_sequence_of_statements and as the only choice of that handler. 7

An *exception*_name of a choice shall not denote an exception declared in a generic formal package. 8

Reason: This is because the compiler doesn't know the identity of such an exception, and thus can't enforce the coverage rules. 8.a

Static Semantics

A choice_parameter_specification declares a *choice parameter*, which is a constant object of type Exception_Occurrence (see 11.4.1). During the handling of an exception occurrence, the choice parameter, if any, of the handler represents the exception occurrence that is being handled. 9

Dynamic Semantics

The execution of a handled_sequence_of_statements consists of the execution of the sequence_of_statements. [The optional handlers are used to handle any exceptions that are propagated by the sequence_of_statements.] 10

Examples

Example of an exception handler: 11

```
{AI12-0178-1} begin                                                    12/5
   Open(File, In_File, "input.txt");    -- see A.8.2
exception
   when E : Name_Error =>
      Put("Cannot open input file : ");
      Put_Line(Ada.Exceptions.Exception_Message(E));  -- see 11.4.1
      raise;
end;
```

Extensions to Ada 83

The syntax rule for exception_handler is modified to allow a choice_parameter_specification. 12.a

{*AI95-00114-01*} Different exception_choices of the same exception_handler may cover the same exception. This allows for "when Numeric_Error | Constraint_Error =>" even though Numeric_Error is a rename of Constraint_Error. This also allows one to "with" two different I/O packages, and then write, for example, "when 12.b/2

Ada.Text_IO.Data_Error | My_Seq_IO.Data_Error =>" even though these might both be renames of the same exception.

Wording Changes from Ada 83

12.c The syntax rule for handled_sequence_of_statements is new. These are now used in all the places where handlers are allowed. This obviates the need to explain (in Clauses 5, 6, 7, and 9) what portions of the program are handled by the handlers. Note that there are more such cases in Ada 95.

12.d The syntax rule for choice_parameter_specification is new.

11.3 Raise Statements and Raise Expressions

1 [A raise_statement raises an exception.]

Syntax

2/2 {*AI95-00361-01*} raise_statement ::= **raise**;
| **raise** *exception_*name [**with** *string_*expression];

2.1/4 {*AI12-0022-1*} {*AI12-0152-1*} raise_expression ::= **raise** *exception_*name [**with** *string_*simple_expression]

2.2/4 {*AI12-0152-1*} If a raise_expression appears within the expression of one of the following contexts, the raise_expression shall appear within a pair of parentheses within the expression:

2.3/4 - object_declaration;
2.4/4 - modular_type_definition;
2.5/4 - floating_point_definition;
2.6/4 - ordinary_fixed_point_definition;
2.7/4 - decimal_fixed_point_definition;
2.8/4 - default_expression;
2.9/4 - ancestor_part.

2.a.1/4 **Reason:** Unlike conditional expressions, this doesn't say "immediately surrounded"; the only requirement is that it is somehow within a pair of parentheses that is part of the expression. We need this restriction in order that raise_expressions cannot be syntactically confused with immediately following constructs (such as aspect_specifications).

2.a.2/4 **Discussion:** We only need to require that a right parenthesis appear somewhere between the raise_expression and the surrounding context; that's all we need to specify in order to eliminate the ambiguities. Moreover, we don't care at all where the left parenthesis is (so long as it is legal, of course).

2.a.3/4 For instance, the following is illegal by this rule:

2.a.4/4
```
Obj : Boolean := Func_Call or else raise TBD_Error with Atomic;
```

2.a.5/4 as the "**with** Atomic" could be part of the **raise_expression** or part of the object declaration. Both of the following are legal:

2.a.6/4
```
Obj : Boolean := Func_Call or else (raise TBD_Error) with Atomic;
Obj : Boolean := (Func_Call or else raise TBD_Error) with Atomic;
```

2.a.7/4 and if the **with** belongs to the raise_expression, then both of the following are legal:

2.a.8/4
```
Obj : Boolean := Func_Call or else (raise TBD_Error with Atomic);
Obj : Boolean := (Func_Call or else raise TBD_Error with Atomic);
```

2.a.9/4 This rule only requires parentheses for raise_expressions that are part of the "top-level" of an expression in one of the named contexts; the raise_expression is either the entire expression, or part of a chain of logical operations. In practice, the raise_expression will almost always be last in interesting top-level expressions; anything that follows it could never be executed, so that should be rare. Other contexts such as conditional expressions, qualified expressions, aggregates, and even function calls, provide the needed parentheses. All of the following are legal, no additional parens are needed:

```
Pre : Boolean  := (if not Is_Valid(Param) then raise Not_Valid_Error);
A : A_Tagged   := (Some_Tagged'(raise TBD_Error) with Comp => 'A');
B : Some_Array := (1, 2, 3, others => raise Not_Valid_Error);
C : Natural    := Func (Val => raise TBD_Error);
```

2.a.10/4

Parentheses that are part of the context of the expression don't count. For instance, the parentheses around the raise_expression are required in the following: 2.a.11/4

```
D : A_Tagged   := ((raise TBD_Error) with Comp => 'A');
```

2.a.12/4

as ancestor_part is one of the contexts that triggers the rule. 2.a.13/4

This English-language rule could have been implemented instead by adding nonterminals initial_expression and initial_relation, which are the same as choice_expression and choice_relation except for the inclusion of membership in initial_relation. Then, initial_expresion could be used in place of expression in all of the contexts noted. We did not do that because of the large amount of change required, both to the grammar and to language rules that refer to the grammar. A complete grammar is given in AI12-0152-1. 2.a.14/4

The use of a raise_expression is illegal in each of modular_type_definition, floating_point_definition, ordinary_fixed_point_definition, and decimal_fixed_point_definition as these uses are required to be static and a raise_expression is never static. We include these in this rule so that Ada text has an unambiguous syntax in these cases. 2.a.15/4

Legality Rules

{*AI12-0022-1*} {*AI12-0159-1*} The *exception*_name, if any, of a raise_statement or raise_expression shall denote an exception. A raise_statement with no *exception*_name (that is, a *re-raise statement*) shall be within a handler, but not within a body enclosed by that handler. 3/4

Name Resolution Rules

{*AI95-00361-01*} {*AI12-0022-1*} {*AI12-0152-1*} The *string*_expression or *string*_simple_expression, if any, of a raise_statement or raise_expression is expected to be of type String. 3.1/4

{*AI12-0022-1*} {*AI12-0159-1*} The expected type for a raise_expression shall be any single type. 3.2/4

Dynamic Semantics

{*AI95-00361-01*} {*AI12-0022-1*} {*AI12-0152-1*} To *raise an exception* is to raise a new occurrence of that exception[, as explained in 11.4]. For the execution of a raise_statement with an *exception*_name, the named exception is raised. Similarly, for the evaluation of a raise_expression, the named exception is raised. [In both of these cases, if a *string*_expression or *string*_simple_expression is present, the expression is evaluated and its value is associated with the exception occurrence.] For the execution of a re-raise statement, the exception occurrence that caused transfer of control to the innermost enclosing handler is raised [again]. 4/4

Proof: {*AI95-00361-01*} The definition of Exceptions.Exception_Message includes a statement that the string is returned (see 11.4.1). We describe the use of the string here so that we don't have an unexplained parameter in this subclause. 4.a.1/2

Implementation Note: For a re-raise statement, the implementation does not create a new Exception_Occurrence, but instead propagates the same Exception_Occurrence value. This allows the original cause of the exception to be determined. 4.a

Term entry: raise an exception — abandon normal program execution so as to draw attention to the fact that the corresponding situation has arisen 4.b/5

NOTE {*AI12-0062-1*} {*AI12-0152-1*} {*AI12-0159-1*} If the evaluation of a *string*_expression or *string*_simple_expression raises an exception, that exception is propagated instead of the one denoted by the *exception*_name of the raise_statement or raise_expression. 4.1/4

Examples

Examples of raise statements: 5

```
{AI95-00433-01} raise Ada.IO_Exceptions.Name_Error;    -- see A.13
raise Queue_Error with "Buffer Full"; -- see 9.11
```

6/2

```
raise;                                 -- re-raise the current exception
```

7

8/5 {AI12-0312-1} -- *For an example of a raise expression, see the Streams Subsystem definitions in 13.13.1.*

Wording Changes from Ada 83

8.a The fact that the name in a raise_statement has to denote an exception is not clear from RM83. Clearly that was the intent, since the italicized part of the syntax rules so indicate, but there was no explicit rule. RM83-1.5(11) doesn't seem to give the italicized parts of the syntax any force.

Extensions to Ada 95

8.b/2 {*AI95-00361-01*} The syntax of a raise_statement is extended to include a string message. This is more convenient than calling Exceptions.Exception_Message (*exception*_name'Identity, *string*_expression), and should encourage the use of message strings when raising exceptions.

Extensions to Ada 2012

8.c/4 {*AI12-0022-1*} {*AI12-0152-1*} {*AI12-0159-1*} **Corrigendum:** The raise_expression is new. This construct is necessary to allow conversion of existing specifications to use preconditions and predicates without changing the exceptions raised. It is considered important enough to be added to Ada 2012 rather than waiting for Ada 2022.

11.4 Exception Handling

1 [When an exception occurrence is raised, normal program execution is abandoned and control is transferred to an applicable exception_handler, if any. To *handle* an exception occurrence is to respond to the exceptional event. To *propagate* an exception occurrence is to raise it again in another context; that is, to fail to respond to the exceptional event in the present context.]

1.a **Ramification:** In other words, if the execution of a given construct raises an exception, but does not handle it, the exception is propagated to an enclosing execution (except in the case of a task_body).

1.b/1 Propagation involves re-raising the same exception occurrence. For example, calling an entry of an uncallable task raises Tasking_Error; this is not propagation.

Dynamic Semantics

2 Within a given task, if the execution of construct *a* is defined by this document to consist (in part) of the execution of construct *b*, then while *b* is executing, the execution of *a* is said to *dynamically enclose* the execution of *b*. The *innermost dynamically enclosing* execution of a given execution is the dynamically enclosing execution that started most recently.

2.a **To be honest:** If the execution of *a* dynamically encloses that of *b*, then we also say that the execution of *b* is *included in* the execution of *a*.

2.b **Ramification:** Examples: The execution of an if_statement dynamically encloses the evaluation of the condition after the **if** (during that evaluation). (Recall that "execution" includes both "elaboration" and "evaluation", as well as other executions.) The evaluation of a function call dynamically encloses the execution of the sequence_of_statements of the function body (during that execution). Note that, due to recursion, several simultaneous executions of the same construct can be occurring at once during the execution of a particular task.

2.c Dynamically enclosing is not defined across task boundaries; a task's execution does not include the execution of any other tasks.

2.d Dynamically enclosing is only defined for executions that are occurring at a given moment in time; if an if_statement is currently executing the sequence_of_statements after **then**, then the evaluation of the condition is no longer dynamically enclosed by the execution of the if_statement (or anything else).

3 When an exception occurrence is raised by the execution of a given construct, the rest of the execution of that construct is *abandoned*; that is, any portions of the execution that have not yet taken place are not performed. The construct is first completed, and then left, as explained in 7.6.1. Then:

4 • If the construct is a task_body, the exception does not propagate further;

4.a **Ramification:** When an exception is raised by the execution of a task_body, there is no dynamically enclosing execution, so the exception does not propagate any further. If the exception occurred during the activation of the task, then the activator raises Tasking_Error, as explained in 9.2, "Task Execution - Task Activation", but we don't define that as propagation; it's a special rule. Otherwise (the exception occurred during the execution of the

handled_sequence_of_statements of the task), the task silently disappears. Thus, abnormal termination of tasks is not always considered to be an error.

- If the construct is the sequence_of_statements of a handled_sequence_of_statements that has a handler with a choice covering the exception, the occurrence is handled by that handler; 5
- Otherwise, the occurrence is *propagated* to the innermost dynamically enclosing execution, which means that the occurrence is raised again in that context. 6

To be honest: As shorthands, we refer to the *propagation of an exception*, and the *propagation by a construct*, if the execution of the construct propagates an exception occurrence. 6.a

When an occurrence is *handled* by a given handler, the choice_parameter_specification, if any, is first elaborated, which creates the choice parameter and initializes it to the occurrence. Then, the sequence_of_statements of the handler is executed; this execution replaces the abandoned portion of the execution of the sequence_of_statements. 7

Ramification: {*AI95-00318-02*} This "replacement" semantics implies that the handler can do pretty much anything the abandoned sequence could do; for example, in a function, the handler can execute a return statement that applies to the function. 7.a/2

Ramification: The rules for exceptions raised in library units, main subprograms and partitions follow from the normal rules, plus the semantics of the environment task described in Clause 10 (for example, the environment task of a partition elaborates library units and calls the main subprogram). If an exception is propagated by the main subprogram, it is propagated to the environment task, which then terminates abnormally, causing the partition to terminate abnormally. Although abnormal termination of tasks is not necessarily an error, abnormal termination of a partition due to an exception *is* an error. 7.b

Term entry: handle an exception — perform some actions in response to the arising of an exception 7.c/5

NOTE {*AI12-0451-1*} Exceptions raised in a declarative_part of a body are not handled by the handlers of the handled_sequence_of_statements of that body. 8/5

11.4.1 The Package Exceptions

Static Semantics

The following language-defined library package exists: 1

```
{AI95-00362-01} {AI95-00400-01} {AI95-00438-01} {AI12-0241-1} {AI12-0302-1} {AI12-0399-1} with Ada.Streams;
package Ada.Exceptions
    with Preelaborate, Nonblocking, Global => in out synchronized is
    type Exception_Id is private
        with Preelaborable_Initialization;
    Null_Id : constant Exception_Id;
    function Exception_Name(Id : Exception_Id) return String;
    function Wide_Exception_Name(Id : Exception_Id) return Wide_String;
    function Wide_Wide_Exception_Name(Id : Exception_Id)
        return Wide_Wide_String;
```

2/5

```
{AI95-00362-01} {AI12-0399-1}     type Exception_Occurrence is limited private
        with Preelaborable_Initialization;
    type Exception_Occurrence_Access is access all Exception_Occurrence;
    Null_Occurrence : constant Exception_Occurrence;
```

3/5

```
{AI95-00329-01} {AI05-0229-1}     procedure Raise_Exception(E : in Exception_Id;
                                      Message : in String := "")
        with No_Return;
    function Exception_Message(X : Exception_Occurrence) return String;
    procedure Reraise_Occurrence(X : in Exception_Occurrence);
```

4/3

5/2 {*AI95-00400-01*}
```
function Exception_Identity(X : Exception_Occurrence)
                            return Exception_Id;
function Exception_Name(X : Exception_Occurrence) return String;
   -- Same as Exception_Name(Exception_Identity(X)).
function Wide_Exception_Name(X : Exception_Occurrence)
   return Wide_String;
   -- Same as Wide_Exception_Name(Exception_Identity(X)).
function Wide_Wide_Exception_Name(X : Exception_Occurrence)
   return Wide_Wide_String;
   -- Same as Wide_Wide_Exception_Name(Exception_Identity(X)).
function Exception_Information(X : Exception_Occurrence) return String;
```

6/2 {*AI95-00438-01*}
```
procedure Save_Occurrence(Target : out Exception_Occurrence;
                          Source : in Exception_Occurrence);
function Save_Occurrence(Source : Exception_Occurrence)
                         return Exception_Occurrence_Access;
```

6.1/2 {*AI95-00438-01*}
```
procedure Read_Exception_Occurrence
   (Stream : not null access Ada.Streams.Root_Stream_Type'Class;
    Item   : out Exception_Occurrence);
procedure Write_Exception_Occurrence
   (Stream : not null access Ada.Streams.Root_Stream_Type'Class;
    Item   : in Exception_Occurrence);
```

6.2/2 {*AI95-00438-01*}
```
for Exception_Occurrence'Read use Read_Exception_Occurrence;
for Exception_Occurrence'Write use Write_Exception_Occurrence;
```

6.3/2 {*AI95-00438-01*}
```
private
   ... -- not specified by the language
end Ada.Exceptions;
```

7 Each distinct exception is represented by a distinct value of type Exception_Id. Null_Id does not represent any exception, and is the default initial value of type Exception_Id. Each occurrence of an exception is represented by a value of type Exception_Occurrence. Null_Occurrence does not represent any exception occurrence, and is the default initial value of type Exception_Occurrence.

8/1 For a prefix E that denotes an exception, the following attribute is defined:

9 E'Identity E'Identity returns the unique identity of the exception. The type of this attribute is Exception_Id.

9.a **Ramification:** In a distributed program, the identity is unique across an entire program, not just across a single partition. Exception propagation works properly across RPC's. An exception can be propagated from one partition to another, and then back to the first, where its identity is known.

10/2 {*AI95-00361-01*} Raise_Exception raises a new occurrence of the identified exception.

10.1/4 {*AI95-00361-01*} {*AI95-00378-01*} {*AI05-0043-1*} {*AI05-0248-1*} {*AI12-0022-1*} {*AI12-0152-1*} Exception_Message returns the message associated with the given Exception_Occurrence. For an occurrence raised by a call to Raise_Exception, the message is the Message parameter passed to Raise_Exception. For the occurrence raised by a raise_statement or raise_expression with an *exception*_name and a *string*_expression or *string*_simple_expression, the message is the *string*_expression or *string*_simple_expression. For the occurrence raised by a raise_statement or raise_expression with an *exception*_name but without a *string*_expression or *string*_simple_expression, the message is a string giving implementation-defined information about the exception occurrence. For an occurrence originally raised in some other manner (including by the failure of a language-defined check), the message is an unspecified string. In all cases, Exception_Message returns a string with lower bound 1.

10.a **Implementation defined:** The information returned by Exception_Message.

10.a.1/3 **Discussion:** {*AI05-0043-1*} There is Implementation Advice about the contents of this string for language-defined checks.

10.b **Ramification:** Given an exception E, the raise_statement:

10.c
```
raise E;
```

is equivalent to this call to Raise_Exception: 10.d

```
Raise_Exception(E'Identity, Message => implementation-defined-string);
```
10.e

{*AI95-00361-01*} Similarly, the raise_statement: 10.e.1/2

```
raise E with "some information";
```
10.e.2/2

is equivalent to this call to Raise_Exception: 10.e.3/2

```
Raise_Exception(E'Identity, Message => "some information");
```
10.e.4/2

{*AI95-00361-01*} Reraise_Occurrence reraises the specified exception occurrence. 10.2/2

Ramification: The following handler: 10.f

```
when others =>
    Cleanup;
    raise;
```
10.g

is equivalent to this one: 10.h

```
when X : others =>
    Cleanup;
    Reraise_Occurrence(X);
```
10.i

Exception_Identity returns the identity of the exception of the occurrence. 11

{*AI95-00400-01*} The Wide_Wide_Exception_Name functions return the full expanded name of the exception, in upper case, starting with a root library unit. For an exception declared immediately within package Standard, the defining_identifier is returned. The result is implementation defined if the exception is declared within an unnamed block_statement. 12/2

Ramification: See the Implementation Permission below. 12.a

To be honest: This name, as well as each prefix of it, does not denote a renaming_declaration. 12.b

Implementation defined: The result of Exceptions.Wide_Wide_Exception_Name for exceptions declared within an unnamed block_statement. 12.c/2

Ramification: Note that we're talking about the name of the exception, not the name of the occurrence. 12.d

{*AI95-00400-01*} The Exception_Name functions (respectively, Wide_Exception_Name) return the same sequence of graphic characters as that defined for Wide_Wide_Exception_Name, if all the graphic characters are defined in Character (respectively, Wide_Character); otherwise, the sequence of characters is implementation defined, but no shorter than that returned by Wide_Wide_Exception_Name for the same value of the argument. 12.1/2

Implementation defined: The sequence of characters of the value returned by Exceptions.Exception_Name (respectively, Exceptions.Wide_Exception_Name) when some of the graphic characters of Exceptions.Wide_Wide_Exception_Name are not defined in Character (respectively, Wide_Character). 12.e/2

{*AI95-00378-01*} {*AI95-00417-01*} The string returned by the Exception_Name, Wide_Exception_Name, and Wide_Wide_Exception_Name functions has lower bound 1. 12.2/2

{*AI95-00378-01*} Exception_Information returns implementation-defined information about the exception occurrence. The returned string has lower bound 1. 13/2

Implementation defined: The information returned by Exception_Information. 13.a

{*AI95-00241-01*} {*AI95-00446-01*} Reraise_Occurrence has no effect in the case of Null_Occurrence. Raise_Exception and Exception_Name raise Constraint_Error for a Null_Id. Exception_Message, Exception_Name, and Exception_Information raise Constraint_Error for a Null_Occurrence. Exception_Identity applied to Null_Occurrence returns Null_Id. 14/2

Ramification: {*AI95-00241-01*} Null_Occurrence can be tested for by comparing Exception_Identity(Occurrence) to Null_Id. 14.a.1/2

Discussion: {*AI95-00446-01*} Raise_Exception was changed so that it always raises an exception and thus can be a No_Return procedure. A similar change was not made for Reraise_Occurrence, as doing so was determined to be a significant incompatibility. It is not unusual to pass an Exception_Occurrence to other code to delay raising it. If there was no exception, passing Null_Occurrence works fine (nothing is raised). Moreover, as there is no test for 14.a.2/2

Null_Occurrence in Ada 95, this is the only way to write such code without using additional flags. Breaking this sort of code is unacceptable.

15 The Save_Occurrence procedure copies the Source to the Target. The Save_Occurrence function uses an allocator of type Exception_Occurrence_Access to create a new object, copies the Source to this new object, and returns an access value designating this new object; [the result may be deallocated using an instance of Unchecked_Deallocation.]

15.a **Ramification:** It's OK to pass Null_Occurrence to the Save_Occurrence subprograms; they don't raise an exception, but simply save the Null_Occurrence.

15.1/2 {*AI95-00438-01*} Write_Exception_Occurrence writes a representation of an exception occurrence to a stream; Read_Exception_Occurrence reconstructs an exception occurrence from a stream (including one written in a different partition).

15.b/5 **Ramification:** {*AI12-0005-1*} These routines are used to define the stream attributes (see 13.13.2) for Exception_Occurrence.

15.c/2 The identity of the exception, as well as the Exception_Name and Exception_Message, have to be preserved across partitions.

15.d/2 The string returned by Exception_Name or Exception_Message on the result of calling the Read attribute on a given stream has to be the same as the value returned by calling the corresponding function on the exception occurrence that was written into the stream with the Write attribute. The string returned by Exception_Information need not be the same, since it is implementation defined anyway.

15.e/2 **Reason:** This is important for supporting writing exception occurrences to external files for post-mortem analysis, as well as propagating exceptions across remote subprogram calls in a distributed system (see E.4).

Paragraph 16 was deleted.

Implementation Permissions

17 An implementation of Exception_Name in a space-constrained environment may return the defining_identifier instead of the full expanded name.

18 The string returned by Exception_Message may be truncated (to no less than 200 characters) by the Save_Occurrence procedure [(not the function)], the Reraise_Occurrence procedure, and the re-raise statement.

18.a **Reason:** The reason for allowing truncation is to ease implementations. The reason for choosing the number 200 is that this is the minimum source line length that implementations have to support, and this feature seems vaguely related since it's usually a “one-liner”. Note that an implementation is allowed to do this truncation even if it supports arbitrarily long lines.

Implementation Advice

19 Exception_Message (by default) and Exception_Information should produce information useful for debugging. Exception_Message should be short (about one line), whereas Exception_Information can be long. Exception_Message should not include the Exception_Name. Exception_Information should include both the Exception_Name and the Exception_Message.

19.a.1/2 **Implementation Advice:** Exception_Information should provide information useful for debugging, and should include the Exception_Name and Exception_Message.

19.a.2/2 **Implementation Advice:** Exception_Message by default should be short, provide information useful for debugging, and should not include the Exception_Name.

19.a **Reason:** It may seem strange to define two subprograms whose semantics is implementation defined. The idea is that a program can print out debugging/error-logging information in a portable way. The program is portable in the sense that it will work in any implementation; it might print out different information, but the presumption is that the information printed out is appropriate for debugging/error analysis on that system.

19.b **Implementation Note:** As an example, Exception_Information might include information identifying the location where the exception occurred, and, for predefined exceptions, the specific kind of language-defined check that failed. There is an implementation trade-off here, between how much information is represented in an Exception_Occurrence, and how much can be passed through a re-raise.

The string returned should be in a form suitable for printing to an error log file. This means that it might need to contain line-termination control characters with implementation-defined I/O semantics. The string should neither start nor end with a newline. 19.c

If an implementation chooses to provide additional functionality related to exceptions and their occurrences, it should do so by providing one or more children of Ada.Exceptions. 19.d

Note that exceptions behave as if declared at library level; there is no “natural scope” for an exception; an exception always exists. Hence, there is no harm in saving an exception occurrence in a data structure, and reraising it later. The reraise has to occur as part of the same program execution, so saving an exception occurrence in a file, reading it back in from a different program execution, and then reraising it is not required to work. This is similar to I/O of access types. Note that it is possible to use RPC to propagate exceptions across partitions. 19.e

Here's one way to implement Exception_Occurrence in the private part of the package. Using this method, an implementation need store only the actual number of characters in exception messages. If the user always uses small messages, then exception occurrences can be small. If the user never uses messages, then exception occurrences can be smaller still: 19.f

```
type Exception_Occurrence(Message_Length : Natural := 200) is
    limited record
        Id : Exception_Id;
        Message : String(1..Message_Length);
    end record;
```
19.g

At the point where an exception is raised, an Exception_Occurrence can be allocated on the stack with exactly the right amount of space for the message — none for an empty message. This is just like declaring a constrained object of the type: 19.h

```
Temp : Exception_Occurrence(10); -- for a 10-character message
```
19.i

After finding the appropriate handler, the stack can be cut back, and the Temp copied to the right place. This is similar to returning an unknown-sized object from a function. It is not necessary to allocate the maximum possible size for every Exception_Occurrence. If, however, the user declares an Exception_Occurrence object, the discriminant will be permanently set to 200. The Save_Occurrence procedure would then truncate the Exception_Message. Thus, nothing is lost until the user tries to save the occurrence. If the user is willing to pay the cost of heap allocation, the Save_Occurrence function can be used instead. 19.j

Note that any arbitrary-sized implementation-defined Exception_Information can be handled in a similar way. For example, if the Exception_Occurrence includes a stack traceback, a discriminant can control the number of stack frames stored. The traceback would be truncated or entirely deleted by the Save_Occurrence procedure — as the implementation sees fit. 19.k

If the internal representation involves pointers to data structures that might disappear, it would behoove the implementation to implement it as a controlled type, so that assignment can either copy the data structures or else null out the pointers. Alternatively, if the data structures being pointed at are in a task control block, the implementation could keep a unique sequence number for each task, so it could tell when a task's data structures no longer exist. 19.l

Using the above method, heap space is never allocated unless the user calls the Save_Occurrence function. 19.m

An alternative implementation would be to store the message strings on the heap when the exception is raised. (It could be the global heap, or it could be a special heap just for this purpose — it doesn't matter.) This representation would be used only for choice parameters. For normal user-defined exception occurrences, the Save_Occurrence procedure would copy the message string into the occurrence itself, truncating as necessary. Thus, in this implementation, Exception_Occurrence would be implemented as a variant record: 19.n

```
type Exception_Occurrence_Kind is (Normal, As_Choice_Param);
```
19.o

```
type Exception_Occurrence(Kind : Exception_Occurrence_Kind := Normal) is
    limited record
        case Kind is
            when Normal =>
                ... -- space for 200 characters
            when As_Choice_Param =>
                ... -- pointer to heap string
        end case;
    end record;
```
19.p

Exception_Occurrences created by the run-time system during exception raising would be As_Choice_Param. User-declared ones would be Normal — the user cannot see the discriminant, and so cannot set it to As_Choice_Param. The strings in the heap would be freed upon completion of the handler. 19.q

This alternative implementation corresponds to a heap-based implementation of functions returning unknown-sized results. 19.r

One possible implementation of Reraise_Occurrence is as follows: 19.s

19.t
```
procedure Reraise_Occurrence(X : in Exception_Occurrence) is
begin
    Raise_Exception(Identity(X), Exception_Message(X));
end Reraise_Occurrence;
```

19.u However, some implementations may wish to retain more information across a re-raise — a stack traceback, for example.

19.v **Ramification:** Note that Exception_Occurrence is a definite subtype. Hence, values of type Exception_Occurrence may be written to an error log for later analysis, or may be passed to subprograms for immediate error analysis.

19.w/2 *This paragraph was deleted.*{*AI95-00400-01*}

20/5 NOTE {*AI12-0021-1*} UTF-8 encoding (see A.4.11) can be used to represent non-ASCII characters in exception messages.

Extensions to Ada 83

20.a The Identity attribute of exceptions is new, as is the package Exceptions.

Inconsistencies With Ada 95

20.b/2 {*AI95-00241-01*} **Amendment Correction:** Exception_Identity of an Exception_Occurrence now is defined to return Null_Id for Null_Occurrence, rather than raising Constraint_Error. This provides a simple way to test for Null_Occurrence. We expect that programs that need Constraint_Error raised will be very rare; they can be easily fixed by explicitly testing for Null_Id or by using Exception_Name instead.

20.c/2 {*AI95-00378-01*} {*AI95-00417-01*} **Amendment Correction:** We now define the lower bound of the string returned from [[Wide_]Wide_]Exception_Name, Exception_Message, and Exception_Information. This makes working with the returned string easier, and is consistent with many other string-returning functions in Ada. This is technically an inconsistency; if a program depended on some other lower bound for the string returned from one of these functions, it could fail when compiled with Ada 2005. Such code is not portable even between Ada 95 implementations, so it should be very rare.

20.d/2 {*AI95-00446-01*} **Amendment Correction:** Raise_Exception now raises Constraint_Error if passed Null_Id. This means that it always raises an exception, and thus we can apply pragma No_Return to it. We expect that programs that call Raise_Exception with Null_Id will be rare, and programs that do that and expect no exception to be raised will be rarer; such programs can be easily fixed by explicitly testing for Null_Id before calling Raise_Exception.

Incompatibilities With Ada 95

20.e/3 {*AI95-00400-01*} {*AI95-00438-01*} {*AI05-0005-1*} Functions Wide_Exception_Name and Wide_Wide_Exception_Name, and procedures Read_Exception_Occurrence and Write_Exception_Occurrence are added to Exceptions. If Exceptions is referenced in a use_clause, and an entity *E* with the same defining_identifier as a new entity in Exceptions is defined in a package that is also referenced in a use_clause, the entity *E* may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur.

Extensions to Ada 95

20.f/2 {*AI95-00362-01*} The package Exceptions is preelaborated, and types Exception_Id and Exception_Occurrence have preelaborable initialization, allowing this package to be used in preelaborated units.

Wording Changes from Ada 95

20.g/2 {*AI95-00361-01*} The meaning of Exception_Message is reworded to reflect that the string can come from a raise_statement as well as a call of Raise_Exception.

20.h/2 {*AI95-00400-01*} Added Wide_Exception_Name and Wide_Wide_Exception_Name because identifiers can now contain characters outside of Latin-1.

Wording Changes from Ada 2005

20.i/3 {*AI05-0043-1*} **Correction:** Added explicit wording that the exception message for language-defined checks is unspecified. The old wording appeared inclusive, but it was not.

11.4.2 Pragmas Assert and Assertion_Policy

1/3 {*AI95-00286-01*} {*AI05-0274-1*} Pragma Assert is used to assert the truth of a boolean expression at a point within a sequence of declarations or statements.

{*AI05-0274-1*} {*AI12-0265-1*} Assert pragmas, subtype predicates (see 3.2.4), preconditions and postconditions (see 6.1.1), type invariants (see 7.3.2), and default initial conditions (see 7.3.3) are collectively referred to as *assertions*; their boolean expressions are referred to as *assertion expressions*. 1.1/5

Term entry: assertion — boolean expression that is expected to be True at run time at certain specified places 1.a/5
Note: Certain pragmas and aspects define various kinds of assertions.

{*AI05-0274-1*} Pragma Assertion_Policy is used to control whether assertions are to be ignored by the implementation, checked at run time, or handled in some implementation-defined manner. 1.2/3

Syntax

{*AI95-00286-01*} The form of a pragma Assert is as follows: 2/2

pragma Assert([Check =>] *boolean*_expression[, [Message =>] *string*_expression]); 3/2

A pragma Assert is allowed at the place where a declarative_item or a statement is allowed. 4/2

{*AI95-00286-01*} The form of a pragma Assertion_Policy is as follows: 5/2

pragma Assertion_Policy(*policy*_identifier); 6/2

{*AI05-0290-1*} **pragma** Assertion_Policy(6.1/3
*assertion*_aspect_mark => *policy*_identifier
{, *assertion*_aspect_mark => *policy*_identifier});

{*AI05-0290-1*} A pragma Assertion_Policy is allowed only immediately within a declarative_part, immediately within a package_specification, or as a configuration pragma. 7/3

Name Resolution Rules

{*AI95-00286-01*} The expected type for the *boolean*_expression of a pragma Assert is any boolean type. The expected type for the *string*_expression of a pragma Assert is type String. 8/2

Reason: We allow any boolean type to be like if_statements and other conditionals; we only allow String for the message in order to match raise_statements. 8.a/2

Legality Rules

{*AI95-00286-01*} {*AI05-0290-1*} {*AI12-0265-1*} {*AI12-0396-1*} The *assertion*_aspect_mark of a pragma Assertion_Policy shall identify an *assertion aspect*, namely one of Assert, Static_Predicate, Dynamic_Predicate, Pre, Pre'Class, Post, Post'Class, Type_Invariant, Type_Invariant'Class, Default_Initial_Condition, or some implementation-defined (assertion) aspect_mark. The *policy*_identifier shall be either Check, Ignore, or some implementation-defined identifier. 9/5

Implementation defined: Implementation-defined *policy*_identifiers and *assertion*_aspect_marks allowed in a pragma Assertion_Policy. 9.a/3

To be honest: {*AI12-0396-1*} "Assert" is considered an "assertion aspect" for the purposes of this rule, even though there is no sort of entity that has an Assert aspect. It can only be specified using an Assert pragma, and applies to a particular point in the execution of a logical thread of control. 9.b/5

Static Semantics

{*AI95-00286-01*} {*AI05-0290-1*} A pragma Assertion_Policy determines for each assertion aspect named in the pragma_argument_associations whether assertions of the given aspect are to be enforced by a runtime check. The *policy*_identifier Check requires that assertion expressions of the given aspect be checked that they evaluate to True at the points specified for the given aspect; the *policy*_identifier Ignore requires that the assertion expression not be evaluated at these points, and the runtime checks not be performed. [Note that for subtype predicate aspects (see 3.2.4), even when the applicable Assertion_Policy is Ignore, the predicate will still be evaluated as part of membership tests and Valid 10/3

attribute_references, and if static, will still have an effect on loop iteration over the subtype, and the selection of case_statement_alternatives and variants.]

10.1/3 {*AI05-0290-1*} If no *assertion_*aspect_marks are specified in the pragma, the specified policy applies to all assertion aspects.

10.2/5 {*AI05-0290-1*} {*AI12-0396-1*} A pragma Assertion_Policy applies to the named assertion aspects in a specific region, and applies to all assertion expressions associated with those aspects specified in that region. A pragma Assertion_Policy given in a declarative_part or immediately within a package_specification applies from the place of the pragma to the end of the innermost enclosing declarative region. The region for a pragma Assertion_Policy given as a configuration pragma is the declarative region for the entire compilation unit (or units) to which it applies.

10.3/3 {*AI05-0290-1*} If a pragma Assertion_Policy applies to a generic_instantiation, then the pragma Assertion_Policy applies to the entire instance.

10.a.1/3 **Ramification:** This means that an Assertion_Policy pragma that occurs in a scope enclosing the declaration of a generic unit but not also enclosing the declaration of a given instance of that generic unit will not apply to assertion expressions occurring within the given instance.

10.4/3 {*AI05-0290-1*} If multiple Assertion_Policy pragmas apply to a given construct for a given assertion aspect, the assertion policy is determined by the one in the innermost enclosing region of a pragma Assertion_Policy specifying a policy for the assertion aspect. If no such Assertion_Policy pragma exists, the policy is implementation defined.

10.a/2 **Implementation defined:** The default assertion policy.

11/2 {*AI95-00286-01*} The following language-defined library package exists:

12/5
```
{AI12-0414-1} package Ada.Assertions
    with Pure is

13/2    Assertion_Error : exception;

14/2    procedure Assert(Check : in Boolean);
        procedure Assert(Check : in Boolean; Message : in String);

15/2 end Ada.Assertions;
```

16/3 {*AI95-00286-01*} {*AI05-0290-1*} A compilation unit containing a check for an assertion (including a pragma Assert) has a semantic dependence on the Assertions library unit.

17/3 *This paragraph was deleted.*{*AI95-00286-01*} {*AI05-0290-1*}

Dynamic Semantics

18/3 {*AI95-00286-01*} {*AI05-0290-1*} If performing checks is required by the Assert assertion policy in effect at the place of a pragma Assert, the elaboration of the pragma consists of evaluating the boolean expression, and if the result is False, evaluating the Message argument, if any, and raising the exception Assertions.Assertion_Error, with a message if the Message argument is provided.

19/2 {*AI95-00286-01*} Calling the procedure Assertions.Assert without a Message parameter is equivalent to:

20/2
```
if Check = False then
   raise Ada.Assertions.Assertion_Error;
end if;
```

21/2 {*AI95-00286-01*} Calling the procedure Assertions.Assert with a Message parameter is equivalent to:

22/2
```
if Check = False then
   raise Ada.Assertions.Assertion_Error with Message;
end if;
```

23/2 {*AI95-00286-01*} The procedures Assertions.Assert have these effects independently of the assertion policy in effect.

Bounded (Run-Time) Errors

{*AI05-0274-1*} {*AI12-0439-1*} It is a bounded error to invoke a potentially blocking operation (see 9.5.1) during the evaluation of an assertion expression associated with a call on, or return from, a protected operation. If the bounded error is detected, Program_Error is raised. If not detected, execution proceeds normally, but if it is invoked within a protected action, it can result in deadlock or a (nested) protected action. 23.1/5

Implementation Requirements

{*AI12-0179-1*} {*AI12-0265-1*} Any postcondition expression, type invariant expression, or default initial condition expression occurring in the specification of a language-defined unit is enabled (see 6.1.1, 7.3.2, and 7.3.3). 23.2/5

Ramification: The Assertion_Policy does not have an effect on such postconditions, invariants, and default initial conditions. This has no execution impact since such assertions shouldn't fail anyway (see the next rule). 23.a/5

{*AI12-0179-1*} {*AI12-0265-1*} The evaluation of any such postcondition, type invariant, or default initial condition expression shall either yield True or propagate an exception from a raise_expression that appears within the assertion expression. 23.3/5

Ramification: In other words, evaluating such an assertion expression will not return a result of False, nor will it propagate an exception other than by evaluating a raise_expression which is syntactically all or part of the assertion expression. 23.b/5

To be honest: Evaluation of any expression might raise Storage_Error. 23.c/5

Reason: This allows the Reference Manual to express semantic requirements as postconditions, invariants, or default initial conditions (which are invariably clearer than English prose would be) while keeping it clear that failing the assertion check (or any other run time check) is not conforming behavior. 23.d/5

{*AI12-0112-1*} Any precondition expression occurring in the specification of a language-defined unit is enabled (see 6.1.1) unless suppressed (see 11.5). Similarly, any predicate checks for a subtype occurring in the specification of a language-defined unit are enabled (see 3.2.4) unless suppressed. 23.4/5

Reason: {*AI12-0005-1*} {*AI12-0112-1*} This allows the Reference Manual to express runtime requirements on the client of a language-defined unit as preconditions or predicates (which are clearer than English prose would be). Some such requirements can be suppressed with pragma Suppress. Ada 2012 and earlier versions did not provide a mechanism to suppress such code. 23.e/5

Implementation Permissions

{*AI95-00286-01*} Assertion_Error may be declared by renaming an implementation-defined exception from another package. 24/2

Reason: This permission is intended to allow implementations which had an implementation-defined Assert pragma to continue to use their originally defined exception. Without this permission, such an implementation would be incorrect, as Exception_Name would return the wrong name. 24.a/2

{*AI95-00286-01*} Implementations may define their own assertion policies. 25/2

{*AI05-0274-1*} {*AI12-0445-1*} If the result of a function call in an assertion is not used to determine the value of the assertion expression, an implementation is permitted to omit the function call. [This permission applies even if the function has side effects.] 26/5

{*AI05-0274-1*} {*AI12-0444-1*} An implementation may disallow the specification of an assertion expression if the evaluation of the expression has a side effect such that an immediate reevaluation of the expression can produce a different value. Similarly, an implementation may disallow the specification of an assertion expression that is checked as part of a call on or return from a callable entity *C*, if the evaluation of the expression has a side effect such that the evaluation of some other assertion expression associated with the same call of (or return from) *C* can produce a different value than in the case when the first expression had not been evaluated. 27/5

27.a/3 **Ramification:** This allows an implementation to reject such assertions. To maximize portability, assertions should not include expressions that contain these sorts of side effects.

27.b/3 **Discussion:** The intended effect of the second part of the rule (the part starting with "Similarly") is that an evaluation of the involved assertion expressions (subtype predicates, type invariants, preconditions and postconditions) in any order yields identical results.

27.c/3 The rule is intended to apply to all of the assertion expressions that are evaluated at the start of call (and similarly for the assertion expressions that are evaluated during the return from a call), but not other assertions actually given in the body, nor between the assertions checked at the start and end of the call. Specifically, a side effect that alters a variable in a function called from a precondition expression that changes the result of a postcondition expression of the same subprogram does *not* trigger these rules unless it also changes the value of a reevaluation of the precondition expression.

Language Design Principles

27.d/4 {*AI12-0005-1*} Our intent is that any assertion expression that violates this Implementation Permission is considered pathological. We definitely want compilers to be able to assume that if you evaluate an assertion expression once and it is True, you don't need to evaluate it again if all you are doing in the meantime is evaluating assertion expressions. We were unable to find wording that had this effect that didn't throw out important other cases (logging, memo functions), so we settled for a strong warning that compilers can reject such pathologies. Perhaps in a future version of Ada we'll be able to tighten this up.

28/5 NOTE {*AI95-00286-01*} {*AI12-0442-1*} {*AI12-0447-1*} Normally, the boolean expression in a pragma Assert should not call functions that have significant side effects when the result of the expression is True, so that the particular assertion policy in effect will not affect normal operation of the program.

Extensions to Ada 95

28.a/2 {*AI95-00286-01*} Pragmas Assert and Assertion_Policy, and package Assertions are new.

Incompatibilities With Ada 2005

28.b/3 {*AI05-0274-1*} There now is an Implementation Permission to reject an assertion expression that calls a function that has a side effect such that an immediate reevalution of the expression could produce a different value. This means that a pragma Assert that works in Ada 2005 might be illegal in Ada 2012 in the unlikely event that the compiler detected such an error. This should be unlikely to occur in practice and it is considered a good thing, as the original expression was tricky and probably was not portable (as order of evaluation is unspecified within an expression). Moreover, no compiler is *required* to reject such expressions, so there is no need for any compiler to change behavior.

Extensions to Ada 2005

28.c/3 {*AI05-0290-1*} Assertion_Policy pragmas are now allowed in more places and can specify behavior for individual kinds of assertions.

Wording Changes from Ada 2012

28.d/5 {*AI12-0112-1*} Added wording that preconditions and predicates given on language-defined units are always checked unless suppressed (that is, they act like language-defined checks). This is not considered an inconsistency, since there are no such preconditions or predicates in Ada 2012.

28.e/5 {*AI12-0179-1*} {*AI12-0265-1*} **Correction:** Added wording that postconditions, type invariants, and default initial conditions given on language-defined units cannot fail. This is not considered an inconsistency, since there are no such postconditions, invariants, or default initial conditions in Ada 2012.

28.f/5 {*AI12-0265-1*} Added default initial conditions to the kinds of assertions (see 7.3.3).

28.g/5 {*AI12-0396-1*} **Correction:** Added a definition of assertion aspects, used in some freezing rules (see 13.14).

11.4.3 Example of Exception Handling

Examples

1/5 {*AI12-0440-1*} Exception handling can be used to separate the detection of an error from the response to that error:

2/5
```
{AI95-00433-01} {AI12-0178-1} package File_System is
    type Data_Type is ...;
    type File_Handle is limited private;
```

```
    File_Not_Found : exception;                                                    3
    procedure Open(F : in out File_Handle; Name : String);
        -- raises File_Not_Found if named file does not exist

    End_Of_File : exception;                                                       4
    procedure Read(F : in out File_Handle; Data : out Data_Type);
        -- raises End_Of_File if the file is not open

{AI12-0178-1}     ...                                                          5/5
private
    ...
end File_System;
```

Reason: {*AI12-0178-1*} The first ... provides a place for Close to be declared, and the second ... provides a place for File_Handle to be completed. 5.a/5

```
{AI12-0178-1} package body File_System is                                      5.1/5
    ...
```

Reason: {*AI12-0178-1*} This ... provides a place for File_Exists and the body of Close to be declared. 5.b/5

```
{AI95-00433-01} {AI12-0178-1}     procedure Open(F : in out File_Handle; Name :  6/5
String) is
    begin
        if File_Exists(Name) then
            ...
        else
            raise File_Not_Found with "File not found: " & Name & ".";
        end if;
    end Open;

    procedure Read(F : in out File_Handle; Data : out Data_Type) is            7
    begin
        if F.Current_Position <= F.Last_Position then
            ...
        else
            raise End_Of_File;
        end if;
    end Read;

    ...                                                                        8
end File_System;                                                               9

{AI12-0178-1} with Ada.Text_IO;                                              10/5
with Ada.Exceptions;
with File_System; use File_System;
use Ada;
procedure Main is
    Verbosity_Desired : Boolean := ...;
begin
    ... -- call operations in File_System
exception
    when End_Of_File =>
        Close(Some_File);
    when Not_Found_Error : File_Not_Found =>
        Text_IO.Put_Line(Exceptions.Exception_Message(Not_Found_Error));
    when The_Error : others =>
        Text_IO.Put_Line("Unknown error:");
        if Verbosity_Desired then
            Text_IO.Put_Line(Exceptions.Exception_Information(The_Error));
        else
            Text_IO.Put_Line(Exceptions.Exception_Name(The_Error));
            Text_IO.Put_Line(Exceptions.Exception_Message(The_Error));
        end if;
        raise;
end Main;
```

{*AI12-0440-1*} In the above example, the File_System package contains information about detecting certain exceptional situations, but it does not specify how to handle those situations. Procedure Main specifies how to handle them; other clients of File_System can have different handlers, even though the exceptional situations arise from the same basic causes. 11/5

Wording Changes from Ada 83

11.a/3 {*AI05-0299-1*} The sections labeled “Exceptions Raised During ...” are subsumed by this subclause, and by parts of Clause 9.

11.5 Suppressing Checks

1/2 {*AI95-00224-01*} *Checking pragmas* give instructions to an implementation on handling language-defined checks. A pragma Suppress gives permission to an implementation to omit certain language-defined checks, while a pragma Unsuppress revokes the permission to omit checks.

1.a/5 **Term entry: suppress a check** — assert that the check cannot fail, and request that the compiler optimize by disabling the check
Note: The compiler is not required to honor this request. Suppressing checks that can fail can cause a program to behave in arbitrary ways.

2/3 {*AI05-0264-1*} A *language-defined check* (or simply, a “check”) is one of the situations defined by this document that requires a check to be made at run time to determine whether some condition is true. A check *fails* when the condition being checked is False, causing an exception to be raised.

2.a **Discussion:** All such checks are defined under “Dynamic Semantics” in clauses and subclauses throughout the standard.

2.b/5 **Term entry: check** — test made during execution to determine whether a language rule has been violated

Syntax

3/2 {*AI95-00224-01*} The forms of checking pragmas are as follows:

4/2 {*AI95-00224-01*} **pragma** Suppress(identifier);

4.1/2 {*AI95-00224-01*} **pragma** Unsuppress(identifier);

5/2 {*AI95-00224-01*} A checking pragma is allowed only immediately within a declarative_part, immediately within a package_specification, or as a configuration pragma.

Legality Rules

6/2 {*AI95-00224-01*} The identifier shall be the name of a check.

7/2 *This paragraph was deleted.*{*AI95-00224-01*}

Static Semantics

7.1/2 {*AI95-00224-01*} A checking pragma applies to the named check in a specific region, and applies to all entities in that region. A checking pragma given in a declarative_part or immediately within a package_specification applies from the place of the pragma to the end of the innermost enclosing declarative region. The region for a checking pragma given as a configuration pragma is the declarative region for the entire compilation unit (or units) to which it applies.

7.2/3 {*AI95-00224-01*} {*AI05-0229-1*} {*AI05-0290-1*} If a checking pragma applies to a generic_instantiation, then the checking pragma also applies to the entire instance.

7.a/3 **Ramification:** {*AI05-0290-1*} This means that a Suppress pragma that occurs in a scope enclosing the declaration of a generic unit but not also enclosing the declaration of a given instance of that generic unit will not apply to constructs within the given instance.

8/2 {*AI95-00224-01*} A pragma Suppress gives permission to an implementation to omit the named check (or every check in the case of All_Checks) for any entities to which it applies. If permission has been given to suppress a given check, the check is said to be *suppressed*.

8.a **Ramification:** A check is suppressed even if the implementation chooses not to actually generate better code. This allows the implementation to raise Program_Error, for example, if the erroneousness is detected.

{*AI95-00224-01*} A pragma Unsuppress revokes the permission to omit the named check (or every check in the case of All_Checks) given by any pragma Suppress that applies at the point of the pragma Unsuppress. The permission is revoked for the region to which the pragma Unsuppress applies. If there is no such permission at the point of a pragma Unsuppress, then the pragma has no effect. A later pragma Suppress can renew the permission. 8.1/2

The following are the language-defined checks: 9

- {*AI12-0309-1*} [The following checks correspond to situations in which the exception Constraint_Error is raised upon failure of a language-defined check.] 10/5

  {*8652/0036*} {*AI95-00176-01*} {*AI95-00231-01*} Access_Check 11/2
  : When evaluating a dereference (explicit or implicit), check that the value of the name is not **null**. When converting to a subtype that excludes null, check that the converted value is not **null**.

  Discriminant_Check 12
  : Check that the discriminants of a composite value have the values imposed by a discriminant constraint. Also, when accessing a record component, check that it exists for the current discriminant values.

  {*AI95-00434-01*} Division_Check 13/2
  : Check that the second operand is not zero for the operations /, **rem** and **mod**.

  Index_Check 14
  : Check that the bounds of an array value are equal to the corresponding bounds of an index constraint. Also, when accessing a component of an array object, check for each dimension that the given index value belongs to the range defined by the bounds of the array object. Also, when accessing a slice of an array object, check that the given discrete range is compatible with the range defined by the bounds of the array object.

  Length_Check 15
  : Check that two arrays have matching components, in the case of array subtype conversions, and logical operators for arrays of boolean components.

  Overflow_Check 16
  : Check that a scalar value is within the base range of its type, in cases where the implementation chooses to raise an exception instead of returning the correct mathematical result.

  {*AI12-0244-1*} Range_Check 17/5
  : Check that a scalar value satisfies a range constraint. Also, for the elaboration of a subtype_indication, check that the constraint (if present) is compatible with the subtype denoted by the subtype_mark. Also, for an aggregate, check that an index or discriminant value belongs to the corresponding subtype. Also, check that when the result of an operation yields an array, the value of each component belongs to the component subtype. Also, for the attributes Value, Wide_Value, and Wide_Wide_Value, check that the given string has the appropriate syntax and value for the base subtype of the prefix of the attribute_reference.

  Tag_Check 18
  : Check that operand tags in a dispatching call are all equal. Check for the correct tag on tagged type conversions, for an assignment_statement, and when returning a tagged limited object from a function.

- {*AI12-0309-1*} [The following checks correspond to situations in which the exception Program_Error is raised upon failure of a language-defined check.] 19/5

  {*AI95-00280*} Accessibility_Check 19.1/2
  : Check the accessibility level of an entity or view.

19.2/2 {*AI95-00280*} Allocation_Check
For an allocator, check that the master of any tasks to be created by the allocator is not yet completed or some dependents have not yet terminated, and that the finalization of the collection has not started.

20 Elaboration_Check
When a subprogram or protected entry is called, a task activation is accomplished, or a generic instantiation is elaborated, check that the body of the corresponding unit has already been elaborated.

21/5 {*AI95-00280*} {*AI12-0309-1*} Program_Error_Check
Other language-defined checks that raise Program_Error: that subtypes with predicates are not used to index an array in a generic unit; that the maximum number of chunks is greater than zero; that the default value of an out parameter is convertible; that there is no misuse of functions in a generic with a class-wide actual type; that there are not colliding External_Tag values; that there is no misuse of operations of unchecked union types.

22/5 • {*AI12-0309-1*} [The following check corresponds to situations in which the exception Storage_Error is raised upon failure of a language-defined check.]

23 Storage_Check
Check that evaluation of an allocator does not require more space than is available for a storage pool. Check that the space available for a task or subprogram has not been exceeded.

23.a **Reason:** We considered splitting this out into three categories: Pool_Check (for allocators), Stack_Check (for stack usage), and Heap_Check (for implicit use of the heap — use of the heap other than through an allocator). Storage_Check would then represent the union of these three. However, there seems to be no compelling reason to do this, given that it is not feasible to split Storage_Error.

23.1/5 • {*AI12-0309-1*} [The following check corresponds to situations in which the exception Tasking_Error is raised upon failure of a language-defined check.]

23.2/5 {*AI12-0309-1*} Tasking_Check
Check that all tasks activated successfully. Check that a called task has not yet terminated.

23.3/5 • {*AI12-0112-1*} {*AI12-0311-1*} [The following checks correspond to situations in which the exception Assertion_Error is raised upon failure of a language-defined check.] For a language-defined unit *U* associated with one of these checks in the list below, the check refers to performance of checks associated with the Pre, Static_Predicate, and Dynamic_Predicate aspects associated with any entity declared in a descendant of *U*, or in an instance of a generic unit which is, or is declared in, a descendant of *U*. Each check is associated with one or more units:

23.4/5 {*AI12-0311-1*} Calendar_Assertion_Check
Calendar.

23.5/5 {*AI12-0311-1*} Characters_Assertion_Check
Characters, Wide_Characters, and Wide_Wide_Characters.

23.6/5 {*AI12-0112-1*} {*AI12-0311-1*} Containers_Assertion_Check
Containers.

23.7/5 {*AI12-0311-1*} Interfaces_Assertion_Check
Interfaces.

23.8/5 {*AI12-0311-1*} IO_Assertion_Check
Sequential_IO, Direct_IO, Text_IO, Wide_Text_IO, Wide_Wide_Text_IO, Storage_IO, Streams.Stream_IO, and Directories.

23.9/5 {*AI12-0311-1*} Numerics_Assertion_Check
Numerics.

{*AI12-0311-1*} Strings_Assertion_Check 23.10/5
Strings.

{*AI12-0311-1*} System_Assertion_Check 23.11/5
System.

Ramification: {*AI12-0311-1*} Any unit *U* is a descendant of itself. 23.b/5

Reason: {*AI12-0112-1*} One could use **pragma** Assertion_Policy to eliminate such checks, but that would require recompiling the language defined packages (the assertion policy that determines whether the assertion checks are made is that used to compile the unit). In addition, we do not want to specify the behavior of language-defined operations if the precondition fails; that is different than the usual behavior of Assertion_Policy. By using Suppress for this purpose, we make it clear that a failed check that is suppressed means erroneous execution. 23.c/5

To be honest: {*AI12-0311-1*} The preceding rule about an instance of a generic where the generic is declared in *U* really extends recursively to handle the case of a generic package `G1` which declares another generic package `G1.G2`, which declares another generic package `G1.G2.G3`, and so on. So if `G1` is declared in some predefined unit *U* then, for purposes of defining these checks, `Some_Instance_Of_G1.G2` is also considered to be declared in *U*. 23.d/5

- {*AI12-0309-1*} [The following check corresponds to all situations in which any predefined exception is raised upon failure of a check.] 24/5

  {*AI05-0290-1*} All_Checks 25/3
  Represents the union of all checks; suppressing All_Checks suppresses all checks other than those associated with assertions. In addition, an implementation is allowed (but not required) to behave as if a pragma Assertion_Policy(Ignore) applies to any region to which pragma Suppress(All_Checks) applies.

  Ramification: {*AI12-0309-1*} All_Checks may include implementation-defined checks. It does not include, however, explicit raises of predefined exceptions (including those mandated for language constructs), nor those propagated from language-defined subprograms. 25.a/5

  To be honest: {*AI05-0005-1*} There are additional checks defined in various Specialized Needs Annexes that are not listed here. Nevertheless, they are included in All_Checks and named in a Suppress pragma on implementations that support the relevant annex. Look up “check, language-defined” in the index to find the complete list. 25.b/3

  Discussion: {*AI05-0290-1*} We don't want to say that assertions are suppressed, because we don't want the potential failure of an assertion to cause erroneous execution (see below). Thus they are excluded from the suppression part of the above rule and then handled with an implicit Ignore policy. 25.c/3

Erroneous Execution

{*AI12-0112-1*} {*AI12-0311-1*} If a given check has been suppressed, and the corresponding error situation occurs, the execution of the program is erroneous. Similarly, if a precondition check has been suppressed and the evaluation of the precondition would have raised an exception, execution is erroneous. 26/5

Reason: {*AI12-0112-1*} It's unclear that a precondition expression that executes **`raise`** *`some_exception`* is an "error situation"; the precondition never actually evaluates to False in that case. Thus, we spell out that case. We only allow suppressing preconditions associated with language-defined units; other preconditions follow the rules of the appropriate Assertion_Policy. 26.a/5

Implementation Permissions

{*AI95-00224-01*} An implementation is allowed to place restrictions on checking pragmas, subject only to the requirement that pragma Unsuppress shall allow any check names supported by pragma Suppress. An implementation is allowed to add additional check names, with implementation-defined semantics. When Overflow_Check has been suppressed, an implementation may also suppress an unspecified subset of the Range_Checks. 27/2

This paragraph was deleted.{*AI95-00224-01*} 27.a/2

Implementation defined: Implementation-defined check names. 27.b

Discussion: For Overflow_Check, the intention is that the implementation will suppress any Range_Checks that are implemented in the same manner as Overflow_Checks (unless they are free). 27.c

27.1/2 {*AI95-00224-01*} An implementation may support an additional parameter on pragma Unsuppress similar to the one allowed for pragma Suppress (see J.10). The meaning of such a parameter is implementation-defined.

27.c.1/2 **Implementation defined:** Existence and meaning of second parameter of pragma Unsuppress.

Implementation Advice

28 The implementation should minimize the code executed for checks that have been suppressed.

28.a.1/2 **Implementation Advice:** Code executed for checks that have been suppressed should be minimized.

28.a **Implementation Note:** However, if a given check comes for free (for example, the hardware automatically performs the check in parallel with doing useful work) or nearly free (for example, the check is a tiny portion of an expensive run-time system call), the implementation should not bother to suppress the check. Similarly, if the implementation detects the failure at compile time and provides a warning message, there is no need to actually suppress the check.

29/5 NOTE 1 {*AI12-0442-1*} There is no guarantee that a suppressed check is actually removed; hence a pragma Suppress is useful only to improve efficiency.

29.1/2 NOTE 2 {*AI95-00224-01*} It is possible to give both a pragma Suppress and Unsuppress for the same check immediately within the same declarative_part. In that case, the last pragma given determines whether or not the check is suppressed. Similarly, it is possible to resuppress a check which has been unsuppressed by giving a pragma Suppress in an inner declarative region.

Examples

30/2 {*AI95-00224-01*} *Examples of suppressing and unsuppressing checks:*

31/2
```
{AI95-00224-01} pragma Suppress(Index_Check);
pragma Unsuppress(Overflow_Check);
```

Extensions to Ada 83

31.a A pragma Suppress is allowed as a configuration pragma. A pragma Suppress without a name is allowed in a package_specification.

31.b Additional check names are added. We allow implementations to define their own checks.

Wording Changes from Ada 83

31.c We define the checks in a distributed manner. Therefore, the long list of what checks apply to what is merely a NOTE.

31.d We have removed the detailed rules about what is allowed in a pragma Suppress, and allow implementations to invent their own. The RM83 rules weren't quite right, and such a change is necessary anyway in the presence of implementation-defined checks.

31.e We make it clear that the difference between a Range_Check and an Overflow_Check is fuzzy. This was true in Ada 83, given RM83-11.6, but it was not clear. We considered removing Overflow_Check from the language or making it obsolescent, just as we did for Numeric_Error. However, we kept it for upward compatibility, and because it may be useful on machines where range checking costs more than overflow checking, but overflow checking still costs something. Different compilers will suppress different checks when asked to suppress Overflow_Check — the nonuniformity in this case is not harmful, and removing it would have a serious impact on optimizers.

31.f Under Access_Check, dereferences cover the cases of selected_component, indexed_component, slice, and attribute that are listed in RM83, as well as the new explicit_dereference, which was included in selected_component in RM83.

Extensions to Ada 95

31.g/2 {*AI95-00224-01*} Pragma Unsuppress is new.

31.h/2 {*AI95-00280-01*} Allocation_Check was added to support suppressing the new check on allocators (see 4.8).

Wording Changes from Ada 95

31.i/2 {*8652/0036*} {*AI95-00176-01*} {*AI95-00224-01*} The description of Access_Check was corrected by the Corrigendum to include the discriminant case. This change was then replaced by the more general notion of checking conversions to subtypes that exclude null in Ada 2005.

31.j/2 {*AI95-00224-01*} The On parameter of pragma Suppress was moved to Annex J (see J.10). This feature's effect is inherently nonportable, depending on the implementation's model of computation. Compiler surveys demonstrated this,

showing that implementations vary widely in the interpretation of these parameters, even on the same target. While this is relatively harmless for Suppress (which is never required to do anything), it would be a significant problem for Unsuppress (we want the checks to be made for all implementations). By moving it, we avoid needing to define the meaning of Unsuppress with an On parameter.

{*AI95-00280-01*} The order of the Program_Error checks was corrected to be alphabetical. 31.k/2

Wording Changes from Ada 2005

{*AI05-0290-1*} {*AI12-0005-1*} The effect of a checking pragma no longer applies inside an inlined subprogram body. While this could change the behavior of a program that depends on a check being suppressed in an inlined body, such a program is erroneous and thus no behavior can be depended upon anyway. It's also likely to be very rare. We make this change so that inlining has no effect on the meaning of the subprogram body (since inlining is never required, this is necessary in order to be able to reason about the body), and so that assertion policies and suppress work the same way for inlining. 31.l/4

Extensions to Ada 2012

{*AI12-0005-1*} {*AI12-0112-1*} {*AI12-0311-1*} The various assertion checks for language-defined packages, such as Calendar_Check and Container_Check, are new. 31.m/5

{*AI12-0309-1*} Program_Error_Check and Tasking_Check are new; all core language-defined checks are now covered with check names. 31.n/5

Wording Changes from Ada 2012

{*AI12-0244-1*} **Correction**: Range_Check is defined to include checks associated with the Value and related attributes. 31.o/5

11.6 Exceptions and Optimization

{*AI05-0299-1*} [This subclause gives permission to the implementation to perform certain "optimizations" that do not necessarily preserve the canonical semantics.] 1/3

Dynamic Semantics

{*AI05-0299-1*} The rest of this Reference Manual (outside this subclause) defines the *canonical semantics* of the language. [The canonical semantics of a given (legal) program determines a set of possible external effects that can result from the execution of the program with given inputs.] 2/3

Ramification: Note that the canonical semantics is a set of possible behaviors, since some reordering, parallelism, and nondeterminism is allowed by the canonical semantics. 2.a

Discussion: {*AI05-0299-1*} The following parts of the canonical semantics are of particular interest to the reader of this subclause: 2.b/3

- Behavior in the presence of abnormal objects and objects with invalid representations (see 13.9.1). 2.c
- Various actions that are defined to occur in an arbitrary order. 2.d
- Behavior in the presence of a misuse of Unchecked_Deallocation, Unchecked_Access, or imported or exported entity (see Clause 13). 2.e

{*AI05-0299-1*} [As explained in 1.1.3, "Conformity of an Implementation", the external effect of a program is defined in terms of its interactions with its external environment. Hence, the implementation can perform any internal actions whatsoever, in any order or in parallel, so long as the external effect of the execution of the program is one that is allowed by the canonical semantics, or by the rules of this subclause.] 3/3

Ramification: Note that an optimization can change the external effect of the program, so long as the changed external effect is an external effect that is allowed by the semantics. Note that the canonical semantics of an erroneous execution allows any external effect whatsoever. Hence, if the implementation can prove that program execution will be erroneous in certain circumstances, there need not be any constraints on the machine code executed in those circumstances. 3.a

Implementation Permissions

4 The following additional permissions are granted to the implementation:

5/5 - {*AI12-0444-1*} An implementation can omit raising an exception when a language-defined check fails. Instead, the operation that failed the check can simply yield an *undefined result*. The exception is required to be raised by the implementation only if, in the absence of raising it, the value of this undefined result would have some effect on the external interactions of the program. In determining this, the implementation shall not presume that an undefined result has a value that belongs to its subtype, nor even to the base range of its type, if scalar. [Having removed the raise of the exception, the canonical semantics will in general allow the implementation to omit the code for the check, and some or all of the operation itself.]

5.a **Ramification:** Even without this permission, an implementation can always remove a check if it cannot possibly fail.

5.b **Reason:** We express the permission in terms of removing the raise, rather than the operation or the check, as it minimizes the disturbance to the canonical semantics (thereby simplifying reasoning). By allowing the implementation to omit the raise, it thereby does not need to "look" at what happens in the exception handler to decide whether the optimization is allowed.

5.c **Discussion:** The implementation can also omit checks if they cannot possibly fail, or if they could only fail in erroneous executions. This follows from the canonical semantics.

5.d **Implementation Note:** This permission is intended to allow normal "dead code removal" optimizations, even if some of the removed code might have failed some language-defined check. However, one may not eliminate the raise of an exception if subsequent code presumes in some way that the check succeeded. For example:

5.e
```
      if X * Y > Integer'Last then
          Put_Line("X * Y overflowed");
      end if;
    exception
      when others =>
          Put_Line("X * Y overflowed");
```

5.e.1 If X*Y does overflow, you may not remove the raise of the exception if the code that does the comparison against Integer'Last presumes that it is comparing it with an in-range Integer value, and hence always yields False.

5.f As another example where a raise may not be eliminated:

5.g
```
      subtype Str10 is String(1..10);
      type P10 is access Str10;
      X : P10 := null;
    begin
      if X.all'Last = 10 then
          Put_Line("Oops");
      end if;
```

5.g.1 In the above code, it would be wrong to eliminate the raise of Constraint_Error on the "X.all" (since X is null), if the code to evaluate 'Last always yields 10 by presuming that X.all belongs to the subtype Str10, without even "looking".

6/5 - {*AI05-0229-1*} {*AI12-0445-1*} If an exception is raised due to the failure of a language-defined check, then upon reaching the corresponding exception_handler (or the termination of the task, if none), the external interactions that have occurred have to reflect only that the exception was raised somewhere within the execution of the sequence_of_statements with the handler (or the task_body), possibly earlier (or later if the interactions are independent of the result of the checked operation) than that defined by the canonical semantics, but not within the execution of some abort-deferred operation or *independent* subprogram that does not dynamically enclose the execution of the construct whose check failed. An independent subprogram is one that is defined outside the library unit containing the construct whose check failed, and for which the Inline aspect is False. Any assignment that occurred outside of such abort-deferred operations or independent subprograms can be disrupted by the raising of the exception, causing the object or its parts to become abnormal, and certain subsequent uses of the object to be erroneous, as explained in 13.9.1.

6.a **Reason:** We allow such variables to become abnormal so that assignments (other than to atomic variables) can be disrupted due to “imprecise” exceptions or instruction scheduling, and so that assignments can be reordered so long as the correct results are produced in the end if no language-defined checks fail.

Ramification: If a check fails, no result dependent on the check may be incorporated in an external interaction. In other words, there is no permission to output meaningless results due to postponing a check. 6.b

Discussion: We believe it is important to state the extra permission to reorder actions in terms of what the programmer can expect at run time, rather than in terms of what the implementation can assume, or what transformations the implementation can perform. Otherwise, how can the programmer write reliable programs? 6.c

{*AI05-0299-1*} This subclause has two conflicting goals: to allow as much optimization as possible, and to make program execution as predictable as possible (to ease the writing of reliable programs). The rules given above represent a compromise. 6.d/3

Consider the two extremes: 6.e

{*AI05-0299-1*} The extreme conservative rule would be to delete this subclause entirely. The semantics of Ada would be the canonical semantics. This achieves the best predictability. It sounds like a disaster from the efficiency point of view, but in practice, implementations would provide modes in which less predictability but more efficiency would be achieved. Such a mode could even be the out-of-the-box mode. In practice, implementers would provide a compromise based on their customer's needs. Therefore, we view this as one viable alternative. 6.f/3

The extreme liberal rule would be “the language does not specify the execution of a program once a language-defined check has failed; such execution can be unpredictable”. This achieves the best efficiency. It sounds like a disaster from the predictability point of view, but in practice it might not be so bad. A user would have to assume that exception handlers for exceptions raised by language-defined checks are not portable. They would have to isolate such code (like all nonportable code), and would have to find out, for each implementation of interest, what behaviors can be expected. In practice, implementations would tend to avoid going so far as to punish their customers too much in terms of predictability. 6.g

{*AI05-0299-1*} The most important thing about this subclause is that users understand what they can expect at run time, and implementers understand what optimizations are allowed. Any solution that makes this subclause contain rules that can interpreted in more than one way is unacceptable. 6.h/3

We have chosen a compromise between the extreme conservative and extreme liberal rules. The current rule essentially allows arbitrary optimizations within a library unit and inlined subprograms reachable from it, but disallow semantics-disrupting optimizations across library units in the absence of inlined subprograms. This allows a library unit to be debugged, and then reused with some confidence that the abstraction it manages cannot be broken by bugs outside the library unit. 6.i

NOTE {*AI05-0299-1*} The permissions granted by this subclause can have an effect on the semantics of a program only if the program fails a language-defined check. 7/3

Wording Changes from Ada 83

RM83-11.6 was unclear. It has been completely rewritten here; we hope this version is clearer. Here's what happened to each paragraph of RM83-11.6: 7.a

- Paragraphs 1 and 2 contain no semantics; they are merely pointing out that anything goes if the canonical semantics is preserved. We have similar introductory paragraphs, but we have tried to clarify that these are not granting any “extra” permission beyond what the rest of the document allows. 7.b
- Paragraphs 3 and 4 are reflected in the “extra permission to reorder actions”. Note that this permission now allows the reordering of assignments in many cases. 7.c
- Paragraph 5 is moved to 4.5, “Operators and Expression Evaluation”, where operator association is discussed. Hence, this is no longer an “extra permission” but is part of the canonical semantics. 7.d
- Paragraph 6 now follows from the general permission to store out-of-range values for unconstrained subtypes. Note that the parameters and results of all the predefined operators of a type are of the unconstrained subtype of the type. 7.e
- Paragraph 7 is reflected in the “extra permission to avoid raising exceptions”. 7.f

{*AI05-0299-1*} {*AI12-0005-1*} We moved subclause 11.5, “Suppressing Checks” (which was numbered 11.7) from after 11.6 to before 11.6, in order to preserve the famous number “11.6” (given the changes to earlier subclauses in Clause 11). 7.g/5

12 Generic Units

A *generic unit* is a program unit that is either a generic subprogram or a generic package. A generic unit is a *template*[, which can be parameterized, and from which corresponding (nongeneric) subprograms or packages can be obtained]. The resulting program units are said to be *instances* of the original generic unit. 1

Term entry: generic unit — template for a (nongeneric) program unit 1.a/5
Note 1: The template can be parameterized by objects, types, subprograms, and packages.
Note 2: Generic units can be used to perform the role that macros sometimes play in other languages.

Term entry: generic instance — nongeneric unit created by the instantiation of a generic unit 1.b/5

[A generic unit is declared by a generic_declaration. This form of declaration has a generic_formal_part declaring any generic formal parameters. An instance of a generic unit is obtained as the result of a generic_instantiation with appropriate generic actual parameters for the generic formal parameters. An instance of a generic subprogram is a subprogram. An instance of a generic package is a package. 2

Generic units are templates. As templates they do not have the properties that are specific to their nongeneric counterparts. For example, a generic subprogram can be instantiated but it cannot be called. In contrast, an instance of a generic subprogram is a (nongeneric) subprogram; hence, this instance can be called but it cannot be used to produce further instances.] 3

12.1 Generic Declarations

[A generic_declaration declares a generic unit, which is either a generic subprogram or a generic package. A generic_declaration includes a generic_formal_part declaring any generic formal parameters. A generic formal parameter can be an object; alternatively (unlike a parameter of a subprogram), it can be a type, a subprogram, or a package.] 1

Syntax

generic_declaration ::= 2
  generic_subprogram_declaration | generic_package_declaration

{*AI05-0183-1*} generic_subprogram_declaration ::= 3/3
  generic_formal_part subprogram_specification
    [aspect_specification];

generic_package_declaration ::= 4
  generic_formal_part package_specification;

Ramification: {*AI05-0183-1*} No syntax change is needed here to allow an aspect_specification; a generic package can have an aspect_specification because a package_specification allows an aspect_specification. 4.a/3

generic_formal_part ::= 5
  generic {generic_formal_parameter_declaration | use_clause}

generic_formal_parameter_declaration ::= 6
  formal_object_declaration
 | formal_type_declaration
 | formal_subprogram_declaration
 | formal_package_declaration

The only form of subtype_indication allowed within a generic_formal_part is a subtype_mark [(that is, the subtype_indication shall not include an explicit constraint)]. The defining name of a generic subprogram shall be an identifier [(not an operator_symbol)]. 7

7.a **Reason:** The reason for forbidding constraints in subtype_indications is that it simplifies the elaboration of generic_declarations (since there is nothing to evaluate), and that it simplifies the matching rules, and makes them more checkable at compile time.

Static Semantics

8/2 {*AI95-00434-01*} A generic_declaration declares a generic unit — a generic package, generic procedure, or generic function, as appropriate.

9 An entity is a *generic formal* entity if it is declared by a generic_formal_parameter_declaration. "Generic formal", or simply "formal", is used as a prefix in referring to objects, subtypes (and types), functions, procedures and packages, that are generic formal entities, as well as to their respective declarations. [Examples: "generic formal procedure" or a "formal integer type declaration".]

9.1/5 {*AI12-0371-1*} The list of generic_formal_parameter_declarations of a generic_formal_part form a *declaration list* of the generic unit.

9.a/5 **Ramification:** Aspect specifications (see 13.1.1) given in a generic formal part can only use declarations given in the formal part, and not those in the visible part of the generic unit.

Dynamic Semantics

10 The elaboration of a generic_declaration has no effect.

11 NOTE 1 Outside a generic unit a name that denotes the generic_declaration denotes the generic unit. In contrast, within the declarative region of the generic unit, a name that denotes the generic_declaration denotes the current instance.

11.a **Proof:** This is stated officially as part of the "current instance" rule in 8.6, "The Context of Overload Resolution". See also 12.3, "Generic Instantiation".

12 NOTE 2 Within a generic subprogram_body, the name of this program unit acts as the name of a subprogram. Hence this name can be overloaded, and it can appear in a recursive call of the current instance. For the same reason, this name cannot appear after the reserved word **new** in a (recursive) generic_instantiation.

13/5 NOTE 3 {*AI12-0447-1*} A default_expression or default_name appearing in a generic_formal_part is not evaluated during elaboration of the generic_formal_part; instead, it is evaluated when used. However, the usual visibility rules apply to any name used in a default, with name resolution performed based on the location of the name within the generic_formal_part.

Examples

14 *Examples of generic formal parts:*

15
```
generic      -- parameterless
```

16
```
generic
   Size : Natural;  -- formal object
```

17
```
generic
   Length : Integer := 200;          -- formal object with a default expression
```

18
```
   Area   : Integer := Length*Length; -- formal object with a default expression
```

19
```
generic
   type Item  is private;                          -- formal type
   type Index is (<>);                             -- formal type
   type Row   is array(Index range <>) of Item;    -- formal type
   with function "<"(X, Y : Item) return Boolean;     -- formal subprogram
```

20 *Examples of generic declarations declaring generic subprograms Exchange and Squaring:*

21
```
generic
   type Elem is private;
procedure Exchange(U, V : in out Elem);
```

22/5
```
{AI12-0178-1} generic
   type Item (<>) is private;
   with function "*"(U, V : Item) return Item is <>;
function Squaring(X : Item) return Item;
```

Example of a generic declaration declaring a generic package: 23

```
generic                                                                    24
   type Item   is private;
   type Vector is array (Positive range <>) of Item;
   with function Sum(X, Y : Item) return Item;
package On_Vectors is
   function Sum  (A, B : Vector) return Vector;
   function Sigma(A    : Vector) return Item;
   Length_Error : exception;
end On_Vectors;
```

Extensions to Ada 83

The syntax rule for generic_formal_parameter_declaration is modified to allow the reserved words **tagged** and **abstract**, to allow formal derived types, and to allow formal packages. 24.a

Use_clauses are allowed in generic_formal_parts. This is necessary in order to allow a use_clause within a formal part to provide direct visibility of declarations within a generic formal package. 24.b

Wording Changes from Ada 83

{*AI05-0299-1*} The syntax for generic_formal_parameter_declaration and formal_type_definition is split up into more named categories. The rules for these categories are moved to the appropriate subclauses. The names of the categories are changed to be more intuitive and uniform. For example, we changed generic_parameter_declaration to generic_formal_parameter_declaration, because the thing it declares is a generic formal, not a generic. In the others, we abbreviate "generic_formal" to just "formal". We can't do that for generic_formal_parameter_declaration, because of confusion with normal formal parameters of subprograms. 24.c/3

Extensions to Ada 2005

{*AI05-0183-1*} An optional aspect_specification can be used in a generic_subprogram_declaration (as well as a generic_package_declaration). This is described in 13.1.1. 24.d/3

Wording Changes from Ada 2012

{*AI12-0371-1*} Defined a formal part as a declaration list, so that the visibility of entities in aspect specifications is properly defined. 24.e/5

12.2 Generic Bodies

The body of a generic unit (a *generic body*) [is a template for the instance bodies. The syntax of a generic body is identical to that of a nongeneric body]. 1

Ramification: We also use terms like "generic function body" and "nongeneric package body". 1.a

Dynamic Semantics

The elaboration of a generic body has no other effect than to establish that the generic unit can from then on be instantiated without failing the Elaboration_Check. If the generic body is a child of a generic package, then its elaboration establishes that each corresponding declaration nested in an instance of the parent (see 10.1.1) can from then on be instantiated without failing the Elaboration_Check. 2

NOTE The syntax of generic subprograms implies that a generic subprogram body is always the completion of a declaration. 3

Examples

Example of a generic procedure body: 4

```
procedure Exchange(U, V : in out Elem) is  -- see 12.1                     5
   T : Elem;  -- the generic formal type
begin
   T := U;
   U := V;
   V := T;
end Exchange;
```

6 *Example of a generic function body:*

7
```
function Squaring(X : Item) return Item is  -- see 12.1
begin
   return X*X;  -- the formal operator "*"
end Squaring;
```

8 *Example of a generic package body:*

9
```
package body On_Vectors is  -- see 12.1
```

10
```
   function Sum(A, B : Vector) return Vector is
      Result : Vector(A'Range); -- the formal type Vector
      Bias   : constant Integer := B'First - A'First;
   begin
      if A'Length /= B'Length then
         raise Length_Error;
      end if;
```

11
```
      for N in A'Range loop
         Result(N) := Sum(A(N), B(N + Bias)); -- the formal function Sum
      end loop;
      return Result;
   end Sum;
```

12
```
   function Sigma(A : Vector) return Item is
      Total : Item := A(A'First); -- the formal type Item
   begin
      for N in A'First + 1 .. A'Last loop
         Total := Sum(Total, A(N)); -- the formal function Sum
      end loop;
      return Total;
   end Sigma;
end On_Vectors;
```

12.3 Generic Instantiation

1 [An instance of a generic unit is declared by a generic_instantiation.]

Language Design Principles

1.a/5 {*AI12-0300-1*} The legality of an instance should be determinable without looking at the generic body. Likewise, the legality of a generic body should be determinable without looking at any instances. Thus, the generic_declaration forms a contract between the body and the instances; if each obeys the rules with respect to the generic_declaration, then no legality problems will arise. This is really a special case of the "legality determinable via semantic dependences" Language Design Principle (see Clause 10), given that a generic_instantiation does not depend semantically upon the generic body, nor vice versa.

1.b Run-time issues are another story. For example, whether parameter passing is by copy or by reference is determined in part by the properties of the generic actuals, and thus cannot be determined at compile time of the generic body. Similarly, the contract model does not apply to Post-Compilation Rules.

Syntax

2/3 {*AI95-00218-03*} {*AI05-0183-1*} generic_instantiation ::=
package defining_program_unit_name **is**
new *generic_package*_name [generic_actual_part]
[aspect_specification];
| [overriding_indicator]
procedure defining_program_unit_name **is**
new *generic_procedure*_name [generic_actual_part]
[aspect_specification];
| [overriding_indicator]
function defining_designator **is**
new *generic_function*_name [generic_actual_part]

[aspect_specification];

generic_actual_part ::= 3
(generic_association {, generic_association})

generic_association ::= 4
[*generic_formal_parameter_*selector_name =>] explicit_generic_actual_parameter

explicit_generic_actual_parameter ::= expression | *variable_*name 5
| *subprogram_*name | *entry_*name | subtype_mark
| *package_instance_*name

A generic_association is *named* or *positional* according to whether or not the *generic_formal_-parameter_*selector_name is specified. Any positional associations shall precede any named associations. 6

{*AI05-0004-1*} {*AI12-0205-1*} The *generic actual parameter* is either the explicit_generic_actual_parameter given in a generic_association for each formal, or the corresponding default_expression, *default_*subtype_mark, or default_name if no generic_association is given for the formal. When the meaning is clear from context, the term "generic actual", or simply "actual", is used as a synonym for "generic actual parameter" and also for the view denoted by one, or the value of one. 7/5

Ramification: {*AI12-0205-1*} Any matching or other Legality Rules that apply to a generic actual are applied to any default_expression, *default_*subtype_mark, or default_name that are used as an actual. 7.a/5

Legality Rules

In a generic_instantiation for a particular kind of program unit [(package, procedure, or function)], the name shall denote a generic unit of the corresponding kind [(generic package, generic procedure, or generic function, respectively)]. 8

{*AI05-0118-1*} The *generic_formal_parameter_*selector_name of a named generic_association shall denote a generic_formal_parameter_declaration of the generic unit being instantiated. If two or more formal subprograms have the same defining name, then named associations are not allowed for the corresponding actuals. 9/3

{*AI05-0118-1*} The generic_formal_parameter_declaration for a positional generic_association is the parameter with the corresponding position in the generic_formal_part of the generic unit being instantiated. 9.1/3

{*AI12-0205-1*} A generic_instantiation shall contain at most one generic_association for each formal. Each formal without an association shall have a default_expression, *default_*subtype_mark, or subprogram_default. 10/5

{*AI12-0418-1*} In a generic unit, Legality Rules are enforced at compile time of the generic_declaration and generic body, given the properties of the formals. In the visible part and formal part of an instance, Legality Rules are enforced at compile time of the generic_instantiation, given the properties of the actuals. In other parts of an instance, Legality Rules are not enforced; this rule does not apply when a given rule explicitly specifies otherwise. 11/5

Reason: {*AI95-00114-01*} Since rules are checked using the properties of the formals, and since these properties do not always carry over to the actuals, we need to check the rules again in the visible part of the instance. For example, only if a tagged type is limited may an extension of it have limited components in the record_extension_part. A formal tagged limited type is limited, but the actual might be nonlimited. Hence any rule that requires a tagged type to be limited runs into this problem. Such rules are rare; in most cases, the rules for matching of formals and actuals guarantee that if the rule is obeyed in the generic unit, then it has to be obeyed in the instance. 11.a/2

11.a.1/3 {*AI05-0005-1*} Ada 2012 addendum: Such Legality Rules are not as rare as the authors of Ada 95 hoped; there are more than 30 of them known at this point. They are indexed under "generic contract issue" and are associated with the boilerplate "In addition to the places where Legality Rules normally apply...". Indeed, there is only one known rule where rechecking in the specification is needed and where rechecking in the private part is *not* wanted (it is in 3.4, but even it needs rechecking when tagged types are involved).

11.b **Ramification:** The "properties" of the formals are determined without knowing anything about the actuals:

11.c/1 - {*8652/0095*} {*AI95-00034-01*} A formal derived subtype is constrained if and only if the ancestor subtype is constrained. A formal array type is constrained if and only if the declarations say so. A formal private type is constrained if it does not have a discriminant part. Other formal subtypes are unconstrained, even though they might be constrained in an instance.

11.d - A formal subtype can be indefinite, even though the copy might be definite in an instance.

11.e - A formal object of mode **in** is not a static constant; in an instance, the copy is static if the actual is.

11.f - A formal subtype is not static, even though the actual might be.

11.g - Formal types are specific, even though the actual can be class-wide.

11.h - The subtype of a formal object of mode **in out** is not static. (This covers the case of AI83-00878.)

11.i - The subtype of a formal parameter of a formal subprogram does not provide an applicable index constraint.

11.j/3 - {*AI05-0239-1*} The profile of a formal subprogram is not subtype conformant with any other profile.

11.k - A generic formal function is not static.

11.l **Ramification:** The exceptions to the above rule about when legality rules are enforced fall into these categories:

11.m - Some rules are checked in the generic declaration, and then again in both the visible and private parts of the instance:

11.n - The parent type of a record extension has to be specific (see 3.9.1). This rule is not checked in the instance body.

11.o - The parent type of a private extension has to be specific (see 7.3). This rule is not checked in the instance body.

11.p/3 - {*AI95-00402-01*} {*AI05-0093-1*} A type with an access discriminant with a default_expression has to be immutably limited. In the generic body, the definition of immutably limited is adjusted in an assume-the-worst manner (thus the rule is checked that way).

11.q - In the declaration of a record extension, if the parent type is nonlimited, then each of the components of the record_extension_part have to be nonlimited (see 3.9.1). In the generic body, this rule is checked in an assume-the-worst manner.

11.r - A preelaborated library unit has to be preelaborable (see 10.2.1). In the generic body, this rule is checked in an assume-the-worst manner.

11.r.1/2 {*AI95-00402-01*} The corrections made by the Corrigendum added a number of such rules, and the Amendment added many more. There doesn't seem to be much value in repeating all of these rules here (as of this writing, there are roughly 33 such rules). As noted below, all such rules are indexed in the AARM.

11.s - For the accessibility rules, the formals have nothing to say about the property in question. Like the above rules, these rules are checked in the generic declaration, and then again in both the visible and private parts of the instance. In the generic body, we have explicit rules that essentially assume the worst (in the cases of type extensions and access-to-subprogram types), and we have runtime checks (in the case of access-to-object types). See 3.9.1, 3.10.2, and 4.6.

11.t We considered runtime checks for access-to-subprogram types as well. However, this would present difficulties for implementations that share generic bodies.

11.u - The rules requiring "reasonable" values for static expressions are ignored when the expected type for the expression is a descendant of a generic formal type other than a generic formal derived type, and do not apply in an instance.

11.v - The rule forbidding two explicit homographs in the same declarative region does not apply in an instance of a generic unit, except that it *does* apply in the declaration of a record extension that appears in the visible part of an instance.

11.w - Some rules do not apply at all in an instance, not even in the visible part:

11.x - Body_stubs are not normally allowed to be multiply nested, but they can be in instances.

11.y Each rule that is an exception is marked with "generic contract issue;" look that up in the index to find them all.

11.z **Ramification:** The Legality Rules are the ones labeled Legality Rules. We are talking about all Legality Rules in the entire language here. Note that, with some exceptions, the legality of a generic unit is checked even if there are no instantiations of the generic unit.

Ramification: {*AI05-0299-1*} {*AI12-0005-1*} The Legality Rules are described here, and the overloading rules were described earlier in this subclause. Presumably, every Static Semantic Item is included indirectly by one of those. Thus, we have covered all the compile-time rules of the language. There is no need to say anything special about the Post-Compilation Rules or the Dynamic Semantic Items. 11.aa/5

Discussion: Here is an example illustrating how this rule is checked: "In the declaration of a record extension, if the parent type is nonlimited, then each of the components of the record_extension_part shall be nonlimited." 11.bb

```
generic                                                                    11.cc
    type Parent is tagged private;
    type Comp is limited private;
package G1 is
    type Extension is new Parent with
        record
            C : Comp; -- Illegal!
        end record;
end G1;
```

The parent type is nonlimited, and the component type is limited, which is illegal. It doesn't matter that one could imagine writing an instantiation with the actual for Comp being nonlimited — we never get to the instance, because the generic itself is illegal. 11.dd/1

On the other hand: 11.ee

```
generic                                                                    11.ff
    type Parent is tagged limited private; -- Parent is limited.
    type Comp is limited private;
package G2 is
    type Extension is new Parent with
        record
            C : Comp; -- OK.
        end record;
end G2;
```

```
type Limited_Tagged is tagged limited null record;                         11.gg
type Non_Limited_Tagged is tagged null record;
```

```
type Limited_Untagged is limited null record;                              11.hh
type Non_Limited_Untagged is null record;
```

```
package Good_1 is new G2(Parent => Limited_Tagged,                         11.ii
                         Comp => Limited_Untagged);
package Good_2 is new G2(Parent => Non_Limited_Tagged,
                         Comp => Non_Limited_Untagged);
package Bad  is new G2(Parent => Non_Limited_Tagged,
                         Comp => Limited_Untagged); -- Illegal!
```

The first instantiation is legal, because in the instance the parent is limited, so the rule is not violated. Likewise, in the second instantiation, the rule is not violated in the instance. However, in the Bad instance, the parent type is nonlimited, and the component type is limited, so this instantiation is illegal. 11.jj

Static Semantics

A generic_instantiation declares an instance; it is equivalent to the instance declaration (a package_-declaration or subprogram_declaration) immediately followed by the instance body, both at the place of the instantiation. 12

Ramification: The declaration and the body of the instance are not "implicit" in the technical sense, even though you can't see them in the program text. Nor are declarations within an instance "implicit" (unless they are implicit by other rules). This is necessary because implicit declarations have special semantics that should not be attached to instances. For a generic subprogram, the profile of a generic_instantiation is that of the instance declaration, by the stated equivalence. 12.a

Ramification: The visible and private parts of a package instance are defined in 7.1, "Package Specifications and Declarations" and 12.7, "Formal Packages". The visible and private parts of a subprogram instance are defined in 8.2, "Scope of Declarations". 12.b

The instance is a copy of the text of the template. [Each use of a formal parameter becomes (in the copy) a use of the actual, as explained below.] An instance of a generic package is a package, that of a generic procedure is a procedure, and that of a generic function is a function. 13

Ramification: An instance is a package or subprogram (because we say so), even though it contains a copy of the generic_formal_part, and therefore doesn't look like one. This is strange, but it's OK, since the syntax rules are overloading rules, and therefore do not apply in an instance. 13.a

13.b **Discussion:** We use a macro-expansion model, with some explicitly-stated exceptions (see below). The main exception is that the interpretation of each construct in a generic unit (especially including the denotation of each name) is determined when the declaration and body of the generic unit (as opposed to the instance) are compiled, and in each instance this interpretation is (a copy of) the template interpretation. In other words, if a construct is interpreted as a name denoting a declaration D, then in an instance, the copy of the construct will still be a name, and will still denote D (or a copy of D). From an implementation point of view, overload resolution is performed on the template, and not on each copy.

13.c We describe the substitution of generic actual parameters by saying (in most cases) that the copy of each generic formal parameter declares a view of the actual. Suppose a name in a generic unit denotes a generic_formal_parameter_declaration. The copy of that name in an instance will denote the copy of that generic_formal_parameter_declaration in the instance. Since the generic_formal_parameter_declaration in the instance declares a view of the actual, the name will denote a view of the actual.

13.d/2 {*AI95-00442-01*} Other properties of the copy (for example, staticness, categories to which types belong) are recalculated for each instance; this is implied by the fact that it's a copy.

13.e/2 {*AI95-00317-01*} Although the generic_formal_part is included in an instance, the declarations in the generic_formal_part are only visible outside the instance in the case of a generic formal package whose formal_package_actual_part includes one or more <> indicators — see 12.7.

14 The interpretation of each construct within a generic declaration or body is determined using the overloading rules when that generic declaration or body is compiled. In an instance, the interpretation of each (copied) construct is the same, except in the case of a name that denotes the generic_declaration or some declaration within the generic unit; the corresponding name in the instance then denotes the corresponding copy of the denoted declaration. The overloading rules do not apply in the instance.

14.a **Ramification:** See 8.6, “The Context of Overload Resolution” for definitions of “interpretation” and “overloading rule”.

14.b Even the generic_formal_parameter_declarations have corresponding declarations in the instance, which declare views of the actuals.

14.c Although the declarations in the instance are copies of those in the generic unit, they often have quite different properties, as explained below. For example a constant declaration in the generic unit might declare a nonstatic constant, whereas the copy of that declaration might declare a static constant. This can happen when the staticness depends on some generic formal.

14.d This rule is partly a ramification of the “current instance” rule in 8.6, “The Context of Overload Resolution”. Note that that rule doesn't cover the generic_formal_part.

14.e/5 {*AI12-0347-1*} Although the overloading rules are not observed in the instance, they are, of course, observed in the generic_instantiation in order to determine the interpretation of the constituents of the generic_instantiation.

14.f Since children are considered to occur within their parent's declarative region, the above rule applies to a name that denotes a child of a generic unit, or a declaration inside such a child.

14.g Since the Syntax Rules are overloading rules, it is possible (legal) to violate them in an instance. For example, it is possible for an instance body to occur in a package_specification, even though the Syntax Rules forbid bodies in package_specifications.

15/5 {*AI12-0407-1*} In an instance, a generic_formal_parameter_declaration declares a view whose properties are identical to those of the actual, except when specified otherwise (in particular, see 6.1.1, “Preconditions and Postconditions”, 12.4, “Formal Objects”, and 12.6, “Formal Subprograms”). Similarly, for a declaration within a generic_formal_parameter_declaration, the corresponding declaration in an instance declares a view whose properties are identical to the corresponding declaration within the declaration of the actual.

15.a **Ramification:** In an instance, there are no “properties” of types and subtypes that come from the formal. The primitive operations of the type come from the formal, but these are declarations in their own right, and are therefore handled separately.

15.b Note that certain properties that come from the actuals are irrelevant in the instance. For example, if an actual type is of a class deeper in the derived-type hierarchy than the formal, it is impossible to call the additional operations of the deeper class in the instance, because any such call would have to be a copy of some corresponding call in the generic unit, which would have been illegal. However, it is sometimes possible to reach into the specification of the instance from outside, and notice such properties. For example, one could pass an object declared in the instance specification to one of the additional operations of the deeper type.

{*AI95-00114-01*} A formal_type_declaration can contain discriminant_specifications, a formal_subprogram_declaration can contain parameter_specifications, and a formal_package_declaration can contain many kinds of declarations. These are all inside the generic unit, and have corresponding declarations in the instance. 15.c/2

This rule implies, for example, that if a subtype in a generic unit is a subtype of a generic formal subtype, then the corresponding subtype in the instance is a subtype of the corresponding actual subtype. 15.d

For a generic_instantiation, if a generic actual is a static [(scalar or string)] subtype, then each use of the corresponding formal parameter within the specification of the instance is considered to be static. (See AI83-00409.) 15.e

Similarly, if a generic actual is a static expression and the corresponding formal parameter has a static [(scalar or string)] subtype, then each use of the formal parameter in the specification of the instance is considered to be static. (See AI83-00505.) 15.f

If a primitive subprogram of a type derived from a generic formal derived tagged type is not overriding (that is, it is a new subprogram), it is possible for the copy of that subprogram in an instance to override a subprogram inherited from the actual. For example: 15.g

```
type T1 is tagged record ... end record;                                                    15.h
{AI12-0005-1} generic                                                                       15.i/5
    type Formal is new T1 with private;
package G is
    type Derived_From_Formal is new Formal with record ... end record;
    procedure Foo(X : in Derived_From_Formal); -- Does not override anything.
end G;
type T2 is new T1 with record ... end record;                                               15.j
procedure Foo(X : in T2);
package Inst is new G(Formal => T2);                                                        15.k
```

In the instance Inst, the declaration of Foo for Derived_From_Formal overrides the Foo inherited from T2. 15.l

Implementation Note: {*8652/0009*} {*AI95-00137-01*} For formal types, an implementation that shares the code among multiple instances of the same generic unit needs to beware that things like parameter passing mechanisms (by-copy vs. by-reference) and aspect_clauses are determined by the actual. 15.m/1

Reason: {*AI12-0407-1*} In particular, we allow differences for aspects that can be specified on generic formal parameters. For instance, Pre (see 6.1.1) can be specified on generic formal subprograms to be added to the Pre of the actual. 15.n/5

[Implicit declarations are also copied, and a name that denotes an implicit declaration in the generic denotes the corresponding copy in the instance. However, for a type declared within the visible part of the generic, a whole new set of primitive subprograms is implicitly declared for use outside the instance, and may differ from the copied set if the properties of the type in some way depend on the properties of some actual type specified in the instantiation. For example, if the type in the generic is derived from a formal private type, then in the instance the type will inherit subprograms from the corresponding actual type. 16

These new implicit declarations occur immediately after the type declaration in the instance, and override the copied ones. The copied ones can be called only from within the instance; the new ones can be called only from outside the instance, although for tagged types, the body of a new one can be executed by a call to an old one.] 17

Proof: This rule is stated officially in 8.3, “Visibility”. 17.a

Ramification: The new ones follow from the class(es) of the formal types. For example, for a type T derived from a generic formal private type, if the actual is Integer, then the copy of T in the instance has a "+" primitive operator, which can be called from outside the instance (assuming T is declared in the visible part of the instance). 17.b

AI83-00398. 17.c

{*AI95-00442-01*} Since an actual type is always in the category determined for the formal, the new subprograms hide all of the copied ones, except for a declaration of "/=" that corresponds to an explicit declaration of "=". Such "/=" operators are special, because unlike other implicit declarations of primitive subprograms, they do not appear by virtue of the class, but because of an explicit declaration of "=". If the declaration of "=" is implicit (and therefore overridden in the instance), then a corresponding implicitly declared "/=" is also overridden. But if the declaration of "=" is explicit (and therefore not overridden in the instance), then a corresponding implicitly declared "/=" is not overridden either, even though it's implicit. 17.d/2

Note that the copied ones can be called from inside the instance, even though they are hidden from all visibility, because the names are resolved in the generic unit — visibility is irrelevant for calls in the instance. 17.e

18 [In the visible part of an instance, an explicit declaration overrides an implicit declaration if they are homographs, as described in 8.3.] On the other hand, an explicit declaration in the private part of an instance overrides an implicit declaration in the instance, only if the corresponding explicit declaration in the generic overrides a corresponding implicit declaration in the generic. Corresponding rules apply to the other kinds of overriding described in 8.3.

18.a **Ramification:** For example:

18.b
```
type Ancestor is tagged null record;
```

18.c
```
generic
    type Formal is new Ancestor with private;
package G is
    type T is new Formal with null record;
    procedure P(X : in T); -- (1)
private
    procedure Q(X : in T); -- (2)
end G;
```

18.d
```
type Actual is new Ancestor with null record;
procedure P(X : in Actual);
procedure Q(X : in Actual);
```

18.e
```
package Instance is new G(Formal => Actual);
```

18.f In the instance, the copy of P at (1) overrides Actual's P, whereas the copy of Q at (2) does not override anything; in implementation terms, it occupies a separate slot in the type descriptor.

18.g/5 **Reason:** {*AI12-0347-1*} The reason for this rule is so a programmer writing a generic_instantiation need not look at the private part of the generic in order to determine which subprograms will be overridden.

Post-Compilation Rules

19 Recursive generic instantiation is not allowed in the following sense: if a given generic unit includes an instantiation of a second generic unit, then the instance generated by this instantiation shall not include an instance of the first generic unit [(whether this instance is generated directly, or indirectly by intermediate instantiations)].

19.a **Discussion:** Note that this rule is not a violation of the generic contract model, because it is not a Legality Rule. Some implementations may be able to check this rule at compile time, but that requires access to all the bodies, so we allow implementations to check the rule at link time.

Dynamic Semantics

20 For the elaboration of a generic_instantiation, each generic_association is first evaluated. If a default is used, an implicit generic_association is assumed for this rule. These evaluations are done in an arbitrary order, except that the evaluation for a default actual takes place after the evaluation for another actual if the default includes a name that denotes the other one. Finally, the instance declaration and body are elaborated.

20.a **Ramification:** Note that if the evaluation of a default depends on some side effect of some other evaluation, the order is still arbitrary.

21 For the evaluation of a generic_association the generic actual parameter is evaluated. Additional actions are performed in the case of a formal object of mode **in** (see 12.4).

21.a **To be honest:** Actually, the actual is evaluated only if evaluation is defined for that kind of construct — we don't actually "evaluate" subtype_marks.

22 NOTE If a formal type is not tagged, then the type is treated as an untagged type within the generic body. Deriving from such a type in a generic body is permitted; the new type does not get a new tag value, even if the actual is tagged. Overriding operations for such a derived type cannot be dispatched to from outside the instance.

22.a **Ramification:** If two overloaded subprograms declared in a generic package specification differ only by the (formal) type of their parameters and results, then there exist legal instantiations for which all calls of these subprograms from outside the instance are ambiguous. For example:

```
generic                                                                    22.b
   type A is (<>);
   type B is private;
package G is
   function Next(X : A) return A;
   function Next(X : B) return B;
end G;

package P is new G(A => Boolean, B => Boolean);                            22.c
-- All calls of P.Next are ambiguous.
```

Ramification: The following example illustrates some of the subtleties of the substitution of formals and actuals: 22.d

```
{AI12-0005-1} generic                                                      22.e/5
    type T1 is private;
    -- A predefined "=" operator is implicitly declared here:
    -- function "="(Left, Right : T1) return Boolean;
    -- Call this "="1.
    ...
package G is
    subtype S1 is T1; -- So we can get our hands on the type from
                      -- outside an instance.
    type T2 is new T1;
    -- An inherited "=" operator is implicitly declared here:
    -- function "="(Left, Right : T2) return Boolean;
    -- Call this "="2.

    T1_Obj : T1 := ...;                                                    22.f
    Bool_1 : Boolean := T1_Obj = T1_Obj;

    T2_Obj : T2 := ...;                                                    22.g
    Bool_2 : Boolean := T2_Obj = T2_Obj;
end G;
...
{AI12-0005-1} package P is                                                 22.h/5
    type My_Int is new Integer;
    -- A predefined "=" operator is implicitly declared here:
    -- function "="(Left, Right : My_Int) return Boolean;
    -- Call this "="3.
    function "="(X, Y : My_Int) return Boolean;
    -- Call this "="4.
    -- "="3 is hidden from all visibility by "="4.
    -- Nonetheless, "="3 can "reemerge" in certain circumstances.
end P;
use P;
...
package I is new G(T1 => My_Int, ...); -- "="5 is declared in I (see below).
use I;

Another_T1_Obj : S1 := 13; -- Can't denote T1, but S1 will do.             22.i
Bool_3 : Boolean := Another_T1_Obj = Another_T1_Obj;

Another_T2_Obj : T2 := 45;                                                 22.j
Bool_4 : Boolean := Another_T2_Obj = Another_T2_Obj;

Double : T2 := T2_Obj + Another_T2_Obj;                                    22.k
```

In the instance I, there is a copy of "="$_1$ (call it "="$_{1i}$) and "="$_2$ (call it "="$_{2i}$). The "="$_{1i}$ and "="$_{2i}$ declare views of the predefined "=" of My_Int (that is, "="$_3$). In the initialization of Bool_1 and Bool_2 in the generic unit G, the names "=" denote "="$_1$ and "="$_2$, respectively. Therefore, the copies of these names in the instances denote "="$_{1i}$ and "="$_{2i}$, respectively. Thus, the initialization of I.Bool_1 and I.Bool_2 call the predefined equality operator of My_Int; they will not call "="$_4$. 22.l

The declarations "="$_{1i}$ and "="$_{2i}$ are hidden from all visibility. This prevents them from being called from outside the instance. 22.m

The declaration of Bool_3 calls "="$_4$. 22.n

The instance I also contains implicit declarations of the primitive operators of T2, such as "=" (call it "="$_5$) and "+". These operations cannot be called from within the instance, but the declaration of Bool_4 calls "="$_5$. 22.o

Examples

23 *Examples of generic instantiations (see 12.1):*

24/5
```
{AI12-0178-1} procedure Swap is new Exchange(Elem => Integer);
procedure Swap is new Exchange(Character);          -- Swap is overloaded
function Square is new Squaring(Integer);   -- "*" of Integer used by default
function Square1 is new Squaring(Item => Matrix, "*" => Matrix_Product);
function Square2 is new Squaring(Matrix, Matrix_Product); -- same as previous
```

25
```
package Int_Vectors is new On_Vectors(Integer, Table, "+");
```

26 *Examples of uses of instantiated units:*

27
```
Swap(A, B);
A := Square(A);
```

28
```
T : Table(1 .. 5) := (10, 20, 30, 40, 50);
N : Integer := Int_Vectors.Sigma(T);  -- 150
                                      -- (see 12.2 for the body of Sigma)
```

29
```
use Int_Vectors;
M : Integer := Sigma(T);  -- 150
```

Inconsistencies With Ada 83

29.a In Ada 83, all explicit actuals are evaluated before all defaults, and the defaults are evaluated in the order of the formal declarations. This ordering requirement is relaxed in Ada 95.

Incompatibilities With Ada 83

29.b We have attempted to remove every violation of the contract model. Any remaining contract model violations should be considered bugs in the RM95. The unfortunate property of reverting to the predefined operators of the actual types is retained for upward compatibility. (Note that fixing this would require subtype conformance rules.) However, tagged types do not revert in this sense.

Extensions to Ada 83

29.c The syntax rule for explicit_generic_actual_parameter is modified to allow a *package_instance_*name.

Wording Changes from Ada 83

29.d The fact that named associations cannot be used for two formal subprograms with the same defining name is moved to AARM-only material, because it is a ramification of other rules, and because it is not of interest to the average user.

29.e/2 {*AI95-00114-01*} The rule that “An explicit explicit_generic_actual_parameter shall not be supplied more than once for a given generic formal parameter” seems to be missing from RM83, although it was clearly the intent.

29.f In the explanation that the instance is a copy of the template, we have left out RM83-12.3(5)'s “apart from the generic formal part”, because it seems that things in the formal part still need to exist in instances. This is particularly true for generic formal packages, where you're sometimes allowed to reach in and denote the formals of the formal package from outside it. This simplifies the explanation of what each name in an instance denotes: there are just two cases: the declaration can be inside or outside (where inside needs to include the generic unit itself). Note that the RM83 approach of listing many cases (see RM83-12.5(5-14)) would have become even more unwieldy with the addition of generic formal packages, and the declarations that occur therein.

29.g We have corrected the definition of the elaboration of a generic_instantiation (RM83-12.3(17)); we don't elaborate entities, and the instance is not “implicit”.

29.h In RM83, there is a rule saying the formal and actual shall match, and then there is much text defining what it means to match. Here, we simply state all the latter text as rules. For example, “A formal foo is matched by an actual greenish bar” becomes “For a formal foo, the actual shall be a greenish bar”. This is necessary to split the Name Resolution Rules from the Legality Rules. Besides, there's really no need to define the concept of matching for generic parameters.

Extensions to Ada 95

29.i/2 {*AI95-00218-03*} An overriding_indicator (see 8.3.1) is allowed on a subprogram instantiation.

Extensions to Ada 2005

29.j/3 {*AI05-0183-1*} An optional aspect_specification can be used in a generic_instantiation. This is described in 13.1.1.

Wording Changes from Ada 2005

{*AI05-0118-1*} **Correction:** Added a definition for positional parameters, as this is missing from Ada 95 and Ada 2005. 29.k/3

Wording Changes from Ada 2012

{*AI12-0205-1*} Added uses of *default_*subtype_marks so formal types can have defaults (see 12.5). 29.l/5

12.4 Formal Objects

[A generic formal object can be used to pass a value or variable to a generic unit.] 1

Language Design Principles

A generic formal object of mode **in** is like a constant initialized to the value of the explicit_generic_actual_parameter. 1.a

A generic formal object of mode **in out** is like a renaming of the explicit_generic_actual_parameter. 1.b

Syntax

{*AI95-00423-01*} {*AI05-0005-1*} {*AI05-0183-1*} formal_object_declaration ::= 2/3
  defining_identifier_list : mode [null_exclusion] subtype_mark [:= default_expression]
    [aspect_specification];
 | defining_identifier_list : mode access_definition [:= default_expression]
    [aspect_specification];

Name Resolution Rules

The expected type for the default_expression, if any, of a formal object is the type of the formal object. 3

For a generic formal object of mode **in**, the expected type for the actual is the type of the formal. 4

{*AI95-00423-01*} For a generic formal object of mode **in out**, the type of the actual shall resolve to the type determined by the subtype_mark, or for a formal_object_declaration with an access_definition, to a specific anonymous access type. If the anonymous access type is an access-to-object type, the type of the actual shall have the same designated type as that of the access_definition. If the anonymous access type is an access-to-subprogram type, the type of the actual shall have a designated profile which is type conformant with that of the access_definition. 5/2

Reason: See the corresponding rule for object_renaming_declarations for a discussion of the reason for this rule. 5.a

Legality Rules

If a generic formal object has a default_expression, then the mode shall be **in** [(either explicitly or by default)]; otherwise, its mode shall be either **in** or **in out**. 6

Ramification: Mode **out** is not allowed for generic formal objects. 6.a

For a generic formal object of mode **in**, the actual shall be an expression. For a generic formal object of mode **in out**, the actual shall be a name that denotes a variable for which renaming is allowed (see 8.5.1). 7

To be honest: The part of this that requires an expression or name is a Name Resolution Rule, but that's too pedantic to worry about. (The part about denoting a variable, and renaming being allowed, is most certainly *not* a Name Resolution Rule.) 7.a

{*AI95-00287-01*} {*AI95-00423-01*} In the case where the type of the formal is defined by an access_definition, the type of the actual and the type of the formal: 8/2

- {*AI95-00423-01*} shall both be access-to-object types with statically matching designated subtypes and with both or neither being access-to-constant types; or 8.1/2

8.2/2 • {*AI95-00423-01*} shall both be access-to-subprogram types with subtype conformant designated profiles.

8.3/5 {*AI95-00423-01*} {*AI12-0287-1*} For a formal_object_declaration of mode **in out** with a null_exclusion or an access_definition that has a null_exclusion, the subtype of the actual matching the formal_object_declaration shall exclude null. In addition, if the actual matching the formal_object_declaration statically denotes the generic formal object of mode **in out** of another generic unit *G*, and the instantiation containing the actual occurs within the body of *G* or within the body of a generic unit declared within the declarative region of *G*, then the declaration of the formal object of *G* shall have a null_exclusion. In addition to the places where Legality Rules normally apply (see 12.3), this rule applies also in the private part of an instance of a generic unit.

8.a/5 **Reason:** {*AI95-00287-01*} {*AI95-00423-01*} {*AI12-0287-1*} This rule prevents "lying". **Null** must never be the value of an object with an explicit null_exclusion. The "in addition" part is an assume-the-worst rule which prevents trouble in generic bodies (including bodies of child units) when the subtype of the formal object of mode **in out** excludes null implicitly. Since a generic formal object of mode **in** is like a constant initialized to the value of the actual, the runtime check performed by the initialization is enough to prevent lying; thus we don't need a Legality Rule for such objects.

Static Semantics

9/2 {*AI95-00255-01*} {*AI95-00423-01*} A formal_object_declaration declares a generic formal object. The default mode is **in**. For a formal object of mode **in**, the nominal subtype is the one denoted by the subtype_mark or access_definition in the declaration of the formal. For a formal object of mode **in out**, its type is determined by the subtype_mark or access_definition in the declaration; its nominal subtype is nonstatic, even if the subtype_mark denotes a static subtype; for a composite type, its nominal subtype is unconstrained if the first subtype of the type is unconstrained[, even if the subtype_mark denotes a constrained subtype].

9.a/2 **Reason:** {*AI95-00255-01*} We require that the subtype is unconstrained because a formal **in out** acts like a renaming, and thus the given subtype is ignored for purposes of matching; any value of the type can be passed. Thus we can assume only that the object is constrained if the first subtype is constrained (and thus there can be no unconstrained subtypes for the type). If we didn't do this, it would be possible to rename or take 'Access of components that could disappear due to an assignment to the whole object.

9.b/2 **Discussion:** {*AI95-00423-01*} The two "even if" clauses are OK even though they don't mention access_definitions; an access subtype can neither be a static subtype nor be a composite type.

10/2 {*AI95-00269-01*} In an instance, a formal_object_declaration of mode **in** is a *full constant declaration* and declares a new stand-alone constant object whose initialization expression is the actual, whereas a formal_object_declaration of mode **in out** declares a view whose properties are identical to those of the actual.

10.a/2 **Ramification:** {*AI95-00287-01*} These rules imply that generic formal objects of mode **in** are passed by copy (or are built-in-place for a limited type), whereas generic formal objects of mode **in out** are passed by reference.

10.b Initialization and finalization happen for the constant declared by a formal_object_declaration of mode **in** as for any constant; see 3.3.1, "Object Declarations" and 7.6, "Assignment and Finalization".

10.c In an instance, the subtype of a generic formal object of mode **in** is as for the equivalent constant. In an instance, the subtype of a generic formal object of mode **in out** is the subtype of the corresponding generic actual.

Dynamic Semantics

11 For the evaluation of a generic_association for a formal object of mode **in**, a constant object is created, the value of the actual parameter is converted to the nominal subtype of the formal object, and assigned to the object[, including any value adjustment — see 7.6].

11.a **Ramification:** This includes evaluating the actual and doing a subtype conversion, which might raise an exception.

11.b **Discussion:** The rule for evaluating a generic_association for a formal object of mode **in out** is covered by the general Dynamic Semantics rule in 12.3.

NOTE The constraints that apply to a generic formal object of mode **in out** are those of the corresponding generic actual parameter (not those implied by the subtype_mark that appears in the formal_object_declaration). Therefore, to avoid confusion, it is recommended that the name of a first subtype be used for the declaration of such a formal object. 12

Ramification: Constraint checks are done at instantiation time for formal objects of mode **in**, but not for formal objects of mode **in out**. 12.a

Extensions to Ada 83

In Ada 83, it is forbidden to pass a (nongeneric) formal parameter of mode **out**, or a subcomponent thereof, to a generic formal object of mode **in out**. This restriction is removed in Ada 95. 12.b

Wording Changes from Ada 83

We make "mode" explicit in the syntax. RM83 refers to the mode without saying what it is. This is also more uniform with the way (nongeneric) formal parameters are defined. 12.c

We considered allowing mode **out** in Ada 95, for uniformity with (nongeneric) formal parameters. The semantics would be identical for modes **in out** and **out**. (Note that generic formal objects of mode **in out** are passed by reference. Note that for (nongeneric) formal parameters that are allowed to be passed by reference, the semantics of **in out** and **out** is the same. The difference might serve as documentation. The same would be true for generic formal objects, if **out** were allowed, so it would be consistent.) We decided not to make this change, because it does not produce any important benefit, and any change has some cost. 12.d

Extensions to Ada 95

{*AI95-00287-01*} A generic formal **in** object can have a limited type. The actual for such an object must be built-in-place via a function_call or aggregate, see 7.5. 12.e/2

{*AI95-00423-01*} A generic formal object can have a null_exclusion or an anonymous access type. 12.f/2

Wording Changes from Ada 95

{*AI95-00255-01*} Clarified that the nominal subtype of a composite formal **in out** object is unconstrained if the first subtype of the type is unconstrained. 12.g/2

{*AI95-00269-01*} Clarified that a formal **in** object can be static when referenced from outside of the instance (by declaring such an object to be a full constant declaration). 12.h/2

Extensions to Ada 2005

{*AI05-0183-1*} An optional aspect_specification can be used in a formal_object_declaration. This is described in 13.1.1. 12.i/3

Extensions to Ada 2012

{*AI12-0287-1*} **Correction:** The Legality Rule for matching null exclusions only applies to formal objects with mode **in out**. (**In** mode formal objects have a run-time check to avoid problems.) This is an extension as some instantiations that were illegal in original Ada 2012 are now legal. 12.j/5

12.5 Formal Types

{*AI95-00442-01*} [A generic formal subtype can be used to pass to a generic unit a subtype whose type is in a certain category of types.] 1/2

Reason: We considered having intermediate syntactic categories formal_integer_type_definition, formal_real_type_definition, and formal_fixed_point_definition, to be more uniform with the syntax rules for non-generic-formal types. However, that would make the rules for formal types slightly more complicated, and it would cause confusion, since formal_discrete_type_definition would not fit into the scheme very well. 1.a

Syntax

{*AI05-0213-1*} formal_type_declaration ::= 2/3
    formal_complete_type_declaration
  | formal_incomplete_type_declaration

{*AI05-0183-1*} {*AI05-0213-1*} {*AI12-0205-1*} formal_complete_type_declaration ::= 2.1/5

type defining_identifier[discriminant_part] **is** formal_type_definition
[**or use** *default*_subtype_mark] [aspect_specification];

2.2/5 {*AI05-0213-1*} {*AI12-0205-1*} formal_incomplete_type_declaration ::=
type defining_identifier[discriminant_part] [**is tagged**]
[**or use** *default*_subtype_mark];

3/2 {*AI95-00251-01*} formal_type_definition ::=
formal_private_type_definition
| formal_derived_type_definition
| formal_discrete_type_definition
| formal_signed_integer_type_definition
| formal_modular_type_definition
| formal_floating_point_definition
| formal_ordinary_fixed_point_definition
| formal_decimal_fixed_point_definition
| formal_array_type_definition
| formal_access_type_definition
| formal_interface_type_definition

Legality Rules

4 For a generic formal subtype, the actual shall be a subtype_mark; it denotes the *(generic) actual subtype*.

4.a **Ramification:** When we say simply "formal" or "actual" (for a generic formal that denotes a subtype) we're talking about the subtype, not the type, since a name that denotes a formal_type_declaration denotes a subtype, and the corresponding actual also denotes a subtype.

Static Semantics

5 A formal_type_declaration declares a *(generic) formal type*, and its first subtype, the *(generic) formal subtype*.

5.a **Ramification:** A subtype (other than the first subtype) of a generic formal type is not a generic formal subtype.

6/3 {*AI95-00442-01*} {*AI05-0213-1*} The form of a formal_type_definition *determines a category (of types)* to which the formal type belongs. For a formal_private_type_definition the reserved words **tagged** and **limited** indicate the category of types (see 12.5.1). The reserved word **tagged** also plays this role in the case of a formal_incomplete_type_declaration. For a formal_derived_type_definition the category of types is the derivation class rooted at the ancestor type. For other formal types, the name of the syntactic category indicates the category of types; a formal_discrete_type_definition defines a discrete type, and so on.

6.a **Reason:** This rule is clearer with the flat syntax rule for formal_type_definition given above. Adding formal_integer_type_definition and others would make this rule harder to state clearly.

6.b/2 {*AI95-00442-01*} We use "category' rather than "class" above, because the requirement that classes are closed under derivation is not important here. Moreover, there are interesting categories that are not closed under derivation. For instance, limited and interface are categories that do not form classes.

Legality Rules

7/2 {*AI95-00442-01*} The actual type shall be in the category determined for the formal.

7.a/2 **Ramification:** {*AI95-00442-01*} For example, if the category determined for the formal is the category of all discrete types, then the actual has to be discrete.

7.b/2 {*AI95-00442-01*} Note that this rule does not require the actual to belong to every category to which the formal belongs. For example, formal private types are in the category of composite types, but the actual need not be composite. Furthermore, one can imagine an infinite number of categories that are just arbitrary sets of types (even though we don't give them names, since they are uninteresting). We don't want this rule to apply to *those* categories.

{*AI95-00114-01*} {*AI95-00442-01*} “Limited” is not an “interesting” category, but “nonlimited” is; it is legal to pass a nonlimited type to a limited formal type, but not the other way around. The reserved word **limited** really represents a category containing both limited and nonlimited types. “Private” is not a category for this purpose; a generic formal private type accepts both private and nonprivate actual types. 7.c/2

{*AI95-00442-01*} It is legal to pass a class-wide subtype as the actual if it is in the right category, so long as the formal has unknown discriminants. 7.d/2

{*AI12-0205-1*} The *default*_subtype_mark, if any, shall denote a subtype which is allowed as an actual subtype for the formal type. 7.1/5

Ramification: {*AI12-0205-1*} This rule is observed at compile time of the generic_declaration, and is consistent with the handling of the default_name of a formal subprogram. This means that a type declared outside of the generic_declaration cannot be used as the *default*_subtype_mark for a formal type that depends on any other formal type. 7.e/5

Static Semantics

{*8652/0037*} {*AI95-00043-01*} {*AI95-00233-01*} {*AI95-00442-01*} {*AI05-0029-1*} {*AI12-0413-1*} [The formal type also belongs to each category that contains the determined category.] The primitive subprograms of the type are as for any type in the determined category. For a formal type other than a formal derived type, these are the predefined operators of the type. For an elementary formal type, the predefined operators are implicitly declared immediately after the declaration of the formal type. For a composite formal type, the predefined operators are implicitly declared either immediately after the declaration of the formal type, or later immediately within the declarative region in which the type is declared according to the rules of 7.3.1. In an instance, the copy of such an implicit declaration declares a view of the predefined operator of the actual type, even if this operator has been overridden for the actual type and even if it is never declared for the actual type, unless the actual type is an untagged record type, in which case it declares a view of the primitive (equality) operator. [The rules specific to formal derived types are given in 12.5.1.] 8/5

Ramification: {*AI95-00442-01*} All properties of the type are as for any type in the category. Some examples: The primitive operations available are as defined by the language for each category. The form of constraint applicable to a formal type in a subtype_indication depends on the category of the type as for a nonformal type. The formal type is tagged if and only if it is declared as a tagged private type, or as a type derived from a (visibly) tagged type. (Note that the actual type might be tagged even if the formal type is not.) 8.a/2

{*AI12-0413-1*} If the primitive equality operator of the (actual) untagged record type is declared abstract, then Program_Error will be raised if the equality operator of the formal type is in fact invoked within an instance of a generic body (see 4.5.2). If the operator is invoked within an instance of the generic spec, the instance is illegal. 8.a.1/5

Reason: {*AI05-0029-1*} The somewhat cryptic phrase “even if it is never declared” is intended to deal with the following oddity: 8.b/3

```
package Q is                                                                    8.c/3
    type T is limited private;
private
    type T is range 1 .. 10;
end Q;

generic                                                                         8.d/3
    type A is array (Positive range <>) of T;
package Q.G is
    A1, A2 : A (1 .. 1);
private
    B : Boolean := A1 = A2;
end Q.G;

with Q.G;                                                                       8.e/3
package R is
   type C is array (Positive range <>) of Q.T;

   package I is new Q.G (C); -- Where is the predefined "=" for C?              8.f/3
end R;
```

An "=" is available for the formal type A in the private part of Q.G. However, no "=" operator is ever declared for type C, because its component type Q.T is limited. Still, in the instance I the name "=" declares a view of the "=" for C which exists-but-is-never-declared. 8.g/3

9 NOTE 1 Generic formal types, like all types, are not named. Instead, a name can denote a generic formal subtype. Within a generic unit, a generic formal type is considered as being distinct from all other (formal or nonformal) types.

9.a **Proof:** This follows from the fact that each formal_type_declaration declares a type.

10 NOTE 2 A discriminant_part is allowed only for certain kinds of types, and therefore only for certain kinds of generic formal types. See 3.7.

10.a/5 **Ramification:** {*AI12-0005-1*} The term "formal floating point type" refers to a type defined by a formal_floating_point_definition. It does not include a formal derived type whose ancestor is a floating point type. Similar terminology applies to the other kinds of formal_type_definition.

Examples

11 *Examples of generic formal types:*

12
```
type Item is private;
type Buffer(Length : Natural) is limited private;
```

13
```
type Enum  is (<>);
type Int   is range <>;
type Angle is delta <>;
type Mass  is digits <>;
```

14
```
type Table is array (Enum) of Item;
```

15 *Example of a generic formal part declaring a formal integer type:*

16
```
generic
   type Rank is range <>;
   First  : Rank := Rank'First;
   Second : Rank := First + 1;  -- the operator "+" of the type Rank
```

Wording Changes from Ada 83

16.a RM83 has separate sections "Generic Formal Xs" and "Matching Rules for Formal Xs" (for various X's) with most of the text redundant between the two. We have combined the two in order to reduce the redundancy. In RM83, there is no "Matching Rules for Formal Types" section; nor is there a "Generic Formal Y Types" section (for Y = Private, Scalar, Array, and Access). This causes, for example, the duplication across all the "Matching Rules for Y Types" sections of the rule that the actual passed to a formal type shall be a subtype; the new organization avoids that problem.

16.b The matching rules are stated more concisely.

16.c We no longer consider the multiplying operators that deliver a result of type *universal_fixed* to be predefined for the various types; there is only one of each in package Standard. Therefore, we need not mention them here as RM83 had to.

Wording Changes from Ada 95

16.d/2 {*8652/0037*} {*AI95-00043-01*} {*AI95-00233-01*} Corrigendum 1 corrected the wording to properly define the location where operators are defined for formal array types. The wording here was inconsistent with that in 7.3.1, "Private Operations". For the Amendment, this wording was corrected again, because it didn't reflect the Corrigendum 1 revisions in 7.3.1.

16.e/2 {*AI95-00251-01*} Formal interface types are defined; see 12.5.5, "Formal Interface Types".

16.f/2 {*AI95-00442-01*} We use "determines a category" rather than class, since not all interesting properties form a class.

Extensions to Ada 2005

16.g/3 {*AI05-0183-1*} An optional aspect_specification can be used in a formal_type_declaration. This is described in 13.1.1.

Wording Changes from Ada 2005

16.h/3 {*AI05-0029-1*} **Correction**: Updated the wording to acknowledge the possibility of operations that are never declared for an actual type but still can be used inside of a generic unit.

16.i/3 {*AI05-0213-1*} {*AI05-0299-1*} Formal incomplete types are added; these are documented as an extension in the next subclause.

Inconsistencies With Ada 2012

{*AI12-0413-1*} **Correction:** Updated the wording to clarify that predefined record equality never reemerges in a generic instantiation. This model was presumed by 4.5.2, but the wording wasn't right for untagged record types with user-defined equality. Therefore, an implementation that strictly implemented the Ada 2012 wording would call the predefined equality for an actual type that is an untagged record type with a user-defined equality, while Ada 2022 implementations would call the primitive (user-defined) equality. This could change the runtime behavior in rare cases. 16.j/5

Extensions to Ada 2012

{*AI12-0205-1*} Generic formal types now can include an optional default subtype_mark. 16.k/5

12.5.1 Formal Private and Derived Types

{*AI95-00442-01*} {*AI05-0213-1*} {*AI12-0445-1*} [In its most general form, the category determined for a formal private type is all types, but the category can be restricted to only nonlimited types or to only tagged types. Similarly, the category for a formal incomplete type is all types but the category can be restricted to only tagged types; unlike other formal types, the actual type can be incompletely defined, and not ready to be frozen (see 13.14). The category determined for a formal derived type is the derivation class rooted at the ancestor type.] 1/5

Proof: {*AI95-00442-01*} {*AI05-0213-1*} The first two rules are given normatively below, and the third rule is given normatively in 12.5; they are repeated here to give a capsule summary of what this subclause is about. 1.a/3

Ramification: {*AI05-0213-1*} Since the actual of a formal incomplete type does not need to be able to be frozen, the actual can be an incomplete type or a partial view before its completion. 1.b/3

Syntax

formal_private_type_definition ::= [[**abstract**] **tagged**] [**limited**] **private** 2

{*AI95-00251-01*} {*AI95-00419-01*} {*AI95-00443-01*} {*AI12-0446-1*} 3/5
formal_derived_type_definition ::=
[**abstract**] [**limited** | **synchronized**] **new** subtype_mark [[**and** interface_list] **with private**]

Legality Rules

If a generic formal type declaration has a known_discriminant_part, then it shall not include a default_expression for a discriminant. 4

Ramification: Consequently, a generic formal subtype with a known_discriminant_part is an indefinite subtype, so the declaration of a stand-alone variable has to provide a constraint on such a subtype, either explicitly, or by its initial value. 4.a

{*AI95-00401-01*} {*AI95-00419-01*} {*AI95-00443-01*} {*AI05-0237-1*} The *ancestor subtype* of a formal derived type is the subtype denoted by the subtype_mark of the formal_derived_type_definition. For a formal derived type declaration, the reserved words **with private** shall appear if and only if the ancestor type is a tagged type; in this case the formal derived type is a private extension of the ancestor type and the ancestor shall not be a class-wide type. [Similarly, an interface_list or the optional reserved words **abstract** or **synchronized** shall appear only if the ancestor type is a tagged type]. The reserved word **limited** or **synchronized** shall appear only if the ancestor type [and any progenitor types] are limited types. The reserved word **synchronized** shall appear (rather than **limited**) if the ancestor type or any of the progenitor types are synchronized interfaces. The ancestor type shall be a limited interface if the reserved word **synchronized** appears. 5/3

Reason: We use the term “ancestor” here instead of “parent” because the actual can be any descendant of the ancestor, not necessarily a direct descendant. 5.a

{*AI95-00419-01*} {*AI05-0005-1*} We require the ancestor type to be limited when **limited** appears so that we avoid oddities like limited integer types. Normally, **limited** means “match anything” for a generic formal, but it was felt that allowing limited elementary types to be declared was just too weird. Integer still matches a formal limited private type; 5.b/3

it is only a problem when the type is known to be elementary. Note that the progenitors are required to be limited by rules in 3.9.4, thus that part of the rule is redundant.

5.c/2 {*AI95-00443-01*} We require that **synchronized** appear if the ancestor or any of the progenitors are synchronized, so that property is explicitly given in the program text – it is not automatically inherited from the ancestors. However, it can be given even if neither the ancestor nor the progenitors are synchronized.

5.1/5 {*AI95-00251-01*} {*AI95-00401-01*} {*AI95-00443-01*} {*AI05-0087-1*} {*AI12-0036-1*} {*AI12-0442-1*} The actual type for a formal derived type shall be a descendant of [the ancestor type and] every progenitor of the formal type. The actual type for a formal derived type shall be tagged if and only if the formal derived type is a private extension. If the reserved word **synchronized** appears in the declaration of the formal derived type, the actual type shall be a synchronized tagged type.

5.d/2 **Proof:** The actual type has to be a descendant of the ancestor type, in order that it be in the correct class. Thus, that part of the rule is redundant.

5.e/3 **Discussion:** {*AI05-0005-1*} For a nonformal private extension, we require the partial view to be synchronized if the full view is synchronized tagged. This does not apply to a formal private extension — it is OK if the formal is not synchronized. Any attempt to extend the formal type will be rechecked in the instance, where the rule disallowing extending a synchronized noninterface type will be enforced. This is consistent with the "no hidden interfaces" rule also applying only to nonformal private extensions, as well as the rule that a limited nonformal private extension implies a limited full type. Formal private extensions are exempted from all these rules to enable the construction of generics that can be used with the widest possible range of types. In particular, an indefinite tagged limited formal private type can match any "concrete" actual tagged type.

5.f/3 {*AI05-0087-1*} A type (including formal types) derived from a limited interface could be nonlimited; we do not want a limited type derived from such an interface to match a nonlimited formal derived type. Otherwise, we could assign limited objects. Thus, we have to explicitly ban this case.

5.g/5 {*AI12-0036-1*} {*AI12-0005-1*} If we allowed actual types whose kind differs from that of the formal derived type, we could allow type conversions that would not be allowed outside of the generic. That would be particularly problematical if the actual is a tagged type with extension components; we could have created an object of the type that is missing those components by converting from the ancestor type to a formal derived type that is not an extension.

6/5 {*AI05-0213-1*} {*AI12-0442-1*} If a formal private or derived subtype is definite, then the actual subtype shall also be definite. If the formal type is nonlimited, the actual type shall be nonlimited.

6.a **Ramification:** On the other hand, for an indefinite formal subtype, the actual can be either definite or indefinite.

6.b/5 **Discussion:** {*AI12-0442-1*} The rule about nonlimited formals applies to both private and derived formal types.

6.1/3 {*AI05-0213-1*} A formal_incomplete_type_declaration declares a formal incomplete type. The only view of a formal incomplete type is an incomplete view. [Thus, a formal incomplete type is subject to the same usage restrictions as any other incomplete type — see 3.10.1.]

7/5 {*AI12-0351-1*} For a generic formal derived type with no discriminant_part, the actual subtype shall be statically compatible with the ancestor subtype. Furthermore:

8/5 - {*AI12-0351-1*} If the ancestor subtype is constrained, the actual subtype shall be constrained;

8.a/5 **Ramification:** {*AI12-0351-1*} In other words, any constraint on the ancestor subtype is considered part of the "contract". Predicates are also considered part of the contract for *any* subtype, via the static compatibility requirement.

9 - If the ancestor subtype is an unconstrained access or composite subtype, the actual subtype shall be unconstrained.

9.a **Reason:** This rule ensures that if a composite constraint is allowed on the formal, one is also allowed on the actual. If the ancestor subtype is an unconstrained scalar subtype, the actual is allowed to be constrained, since a scalar constraint does not cause further constraints to be illegal.

10 - If the ancestor subtype is an unconstrained discriminated subtype, then the actual shall have the same number of discriminants, and each discriminant of the actual shall correspond to a discriminant of the ancestor, in the sense of 3.7.

10.a **Reason:** This ensures that if a discriminant constraint is given on the formal subtype, the corresponding constraint in the instance will make sense, without additional runtime checks. This is not necessary for arrays, since the bounds cannot be overridden in a type extension. An unknown_discriminant_part may be used to relax these matching requirements.

- {*AI95-00231-01*} If the ancestor subtype is an access subtype, the actual subtype shall exclude null if and only if the ancestor subtype excludes null. 10.1/2

  Reason: We require that the "excludes null" property match, because it would be difficult to write a correct generic for a formal access type without knowing this property. Many typical algorithms and techniques will not work for a subtype that excludes null (setting an unused component to **null**, default-initialized objects, and so on). We want this sort of requirement to be reflected in the contract of the generic. 10.b/2

{*AI05-0213-1*} The declaration of a formal derived type shall not have a known_discriminant_part. For a generic formal private or incomplete type with a known_discriminant_part: 11/3

- The actual type shall be a type with the same number of discriminants. 12
- The actual subtype shall be unconstrained. 13
- The subtype of each discriminant of the actual type shall statically match the subtype of the corresponding discriminant of the formal type. 14

  Reason: We considered defining the first and third rule to be called "subtype conformance" for discriminant_parts. We rejected that idea, because it would require implicit (inherited) discriminant_parts, which seemed like too much mechanism. 14.a

{*AI12-0444-1*} [For a generic formal type with an unknown_discriminant_part, the actual may have discriminants, though that is not required, and may be definite or indefinite.] 15/5

{*AI12-0095-1*} When enforcing Legality Rules, for the purposes of determining within a generic body whether a type is unconstrained in any partial view, a discriminated subtype is considered to have a constrained partial view if it is a descendant of an untagged generic formal private or derived type. 15.1/4

Static Semantics

{*AI95-00442-01*} The category determined for a formal private type is as follows: 16/2

Type Definition	*Determined Category* 17/2
limited private	the category of all types
private	the category of all nonlimited types
tagged limited private	the category of all tagged types
tagged private	the category of all nonlimited tagged types

[The presence of the reserved word **abstract** determines whether the actual type may be abstract.] 18

{*AI05-0213-1*} The category determined for a formal incomplete type is the category of all types, unless the formal_type_declaration includes the reserved word **tagged**; in this case, it is the category of all tagged types. 18.1/3

A formal private or derived type is a private or derived type, respectively. A formal derived tagged type is a private extension. [A formal private or derived type is abstract if the reserved word **abstract** appears in its declaration.] 19

{*AI95-00233-01*} {*AI05-0110-1*} For a formal derived type, the characteristics (including components, but excluding discriminants if there is a new discriminant_part), predefined operators, and inherited user-defined primitive subprograms are determined by its ancestor type and its progenitor types (if any), in the same way that those of a derived type are determined by those of its parent type and its progenitor types (see 3.4 and 7.3.1). 20/3

{*8652/0038*} {*AI95-00202*} {*AI95-00233-01*} {*AI95-00401-01*} {*AI05-0029-1*} {*AI05-0110-1*} In an instance, the copy of an implicit declaration of a primitive subprogram of a formal derived type declares a view of the corresponding primitive subprogram of the ancestor or progenitor of the formal derived type, even if this primitive has been overridden for the actual type and even if it is never declared for the actual 21/3

type. When the ancestor or progenitor of the formal derived type is itself a formal type, the copy of the implicit declaration declares a view of the corresponding copied operation of the ancestor or progenitor. [In the case of a formal private extension, however, the tag of the formal type is that of the actual type, so if the tag in a call is statically determined to be that of the formal type, the body executed will be that corresponding to the actual type.]

21.a/3 **Ramification:** {*AI95-00401-01*} {*AI05-0239-1*} The above rule defining the properties of primitive subprograms in an instance applies even if the subprogram has been overridden or hidden for the actual type. This rule is necessary for untagged types, because their primitive subprograms might have been overridden by operations that are not subtype conformant with the operations defined for the class. For tagged types, the rule still applies, but the primitive subprograms will dispatch to the appropriate implementation based on the type and tag of the operands. Even for tagged types, the formal parameter names and default_expressions are determined by those of the primitive subprograms of the specified ancestor type (or progenitor type, for subprograms inherited from an interface type).

21.b/4 **To be honest:** {*AI12-0030-1*} The availability of stream attributes is not formally a characteristic of a type, but it is still determined by the ancestor type for a formal derived type in the same way as the characteristics are. Availability is rechecked in the instance specification.

21.1/5 {*AI12-0419-1*} In an instance, the implicitly composed and additive aspects (see 13.1.1) of a formal type are those of the actual; for a nonoverridable aspect, a formal derived type inherits the aspect if the ancestor or any progenitor has the aspect, according to the rules given in 13.1.

22/1 For a prefix S that denotes a formal indefinite subtype, the following attribute is defined:

23/3 S'Definite {*AI05-0264-1*} S'Definite yields True if the actual subtype corresponding to S is definite; otherwise, it yields False. The value of this attribute is of the predefined type Boolean.

23.a/5 **Discussion:** {*AI95-00114-01*} {*AI12-0005-1*} Whether an actual subtype is definite or indefinite may have a major effect on the algorithm used in a generic. For example, in a generic I/O package, whether to use fixed-length or variable-length records could depend on whether the actual is definite or indefinite. This attribute is essentially a replacement for the Constrained attribute, which is now obsolescent.

Dynamic Semantics

23.1/3 {*AI95-00158-01*} {*AI05-0071-1*} In the case where a formal type has unknown discriminants, and the actual type is a class-wide type *T*'Class:

23.2/2 - {*AI95-00158-01*} For the purposes of defining the primitive operations of the formal type, each of the primitive operations of the actual type is considered to be a subprogram (with an intrinsic calling convention — see 6.3.1) whose body consists of a dispatching call upon the corresponding operation of *T*, with its formal parameters as the actual parameters. If it is a function, the result of the dispatching call is returned.

23.3/2 - {*AI95-00158-01*} If the corresponding operation of *T* has no controlling formal parameters, then the controlling tag value is determined by the context of the call, according to the rules for tag-indeterminate calls (see 3.9.2 and 5.2). In the case where the tag would be statically determined to be that of the formal type, the call raises Program_Error. If such a function is renamed, any call on the renaming raises Program_Error.

23.b/2 **Discussion:** As it states in 6.3.1, the convention of an inherited subprogram of a generic formal tagged type with unknown discriminants is intrinsic.

23.c/2 In the case of a corresponding primitive of T with no controlling formal parameters, the context of the call provides the controlling tag value for the dispatch. If no tag is provided by context, Program_Error is raised rather than resorting to a nondispatching call. For example:

23.d/2
```
generic
   type NT(<>) is new T with private;
    -- Assume T has operation "function Empty return T;"
package G is
   procedure Test(X : in out NT);
end G;
```

```
package body G is                                                          23.e/2
   procedure Test(X : in out NT) is
   begin
      X := Empty;  -- Dispatching based on X'Tag takes
                   -- place if actual is class-wide.
      declare
          Y : NT := Empty;
                   -- If actual is class-wide, this raises Program_Error
                   -- as there is no tag provided by context.
      begin
          X := Y;  -- We never get this far.
      end;
   end Test;
end G;
```

```
type T1 is new T with null record;                                         23.f/2
package I is new G(T1'Class);
```

NOTE 1 The actual type can be abstract only if the formal type is abstract (see 3.9.3). 27

Reason: This is necessary to avoid contract model problems, since one or more of its primitive subprograms are abstract; it is forbidden to create objects of the type, or to declare functions returning the type. 27.a

Ramification: On the other hand, it is OK to pass a nonabstract actual to an abstract formal — **abstract** on the formal indicates that the actual might be abstract. 27.b

NOTE 2 {*AI12-0447-1*} If the formal has a discriminant_part, the actual can be either definite or indefinite. Otherwise, the actual can only be definite. 28/5

Incompatibilities With Ada 83

Ada 83 does not have unknown_discriminant_parts, so it allows indefinite subtypes to be passed to definite formals, and applies a legality rule to the instance body. This is a contract model violation. Ada 95 disallows such cases at the point of the instantiation. The workaround is to add (<>) as the discriminant_part of any formal subtype if it is intended to be used with indefinite actuals. If that's the intent, then there can't be anything in the generic body that would require a definite subtype. 28.a

The check for discriminant subtype matching is changed from a runtime check to a compile-time check. 28.b

Extensions to Ada 95

{*AI95-00251-01*} {*AI95-00401-01*} {*AI95-00419-01*} {*AI95-00443-01*} A generic formal derived type can include progenitors (interfaces) as well as a primary ancestor. It also may include **limited** to indicate that it is a limited type, and **synchronized** to indicate that it is a synchronized type. 28.c/2

Wording Changes from Ada 95

{*8652/0038*} {*AI95-00202-01*} **Corrigendum:** Corrected wording to define the operations that are inherited when the ancestor of a formal type is itself a formal type to avoid anomalies. 28.d/2

{*AI95-00158-01*} Added a semantic description of the meaning of operations of an actual class-wide type, as such a type does not have primitive operations of its own. 28.e/2

{*AI95-00231-01*} Added a matching rule for access subtypes that exclude null. 28.f/2

{*AI95-00233-01*} The wording for the declaration of implicit operations is corrected to be consistent with 7.3.1 as modified by Corrigendum 1. 28.g/2

{*AI95-00442-01*} We change to “determines a category” as that is the new terminology (it avoids confusion, since not all interesting properties form a class). 28.h/2

Incompatibilities With Ada 2005

{*AI05-0087-1*} **Correction:** Added wording to prevent a limited type from being passed to a nonlimited formal derived type. While this was allowed, it would break the contract for the limited type, so hopefully no programs actually depend on that. 28.i/3

Extensions to Ada 2005

{*AI05-0213-1*} Formal incomplete types are a new kind of generic formal; these can be instantiated with incomplete types and unfrozen private types. 28.j/3

Wording Changes from Ada 2005

28.k/3 {*AI05-0029-1*} **Correction:** Updated the wording to acknowledge the possibility of operations that are never declared for an actual type but still can be used inside of a generic unit.

28.l/3 {*AI05-0071-1*} **Correction:** Fixed hole that failed to define what happened for "=" for an untagged private type whose actual is class-wide.

28.m/3 {*AI05-0110-1*} **Correction:** Revised the wording for inheritance of characteristics and operations of formal derived types to be reuse the rules as defined for derived types; this should eliminate holes in the wording which have plagued us since Ada 95 was defined (it has been "corrected" four previous times).

28.n/3 {*AI05-0237-1*} **Correction:** Added missing rule for the ancestors of formal derived types. The added rule would formally be incompatible, but since it would be impossible to instantiate any such generic, this cannot happen outside of test suites and thus is not documented as an incompatibility.

Incompatibilities With Ada 2012

28.o/4 {*AI12-0036-1*} **Corrigendum:** Added a requirement that a tagged type only match a formal derived type that is a private extension. This is necessary to prevent type conversions that would not be allowed outside of the generic. We expect that this will be rare, as it only can happen if the formal derived type does not accurately describe the actual type; in most such cases, extension will be desired and a private extension used so that is allowed.

28.p/5 {*AI12-0351-1*} **Correction:** The predicates of an ancestor subtype are considered part of the contract for a formal derived type, even if the ancestor subtype is unconstrained. This means, for instance, if the ancestor subtype is a subtype of Float with a predicate, then an actual subtype with a different predicate is illegal in Ada 2022 while it would have been allowed in Ada 2012. Cases like this are quite unlikely and will be detected at compile-time if they occur.

Wording Changes from Ada 2012

28.q/4 {*AI12-0095-1*} **Corrigendum:** The assume the worst rule for determining within a generic body whether a type is unconstrained in any partial view was moved here. While AI05-0041-1 added it to 3.10.2, it's also needed (at least) in 4.6 and 6.4.1. Thus, it was moved here so that it applies generally.

12.5.2 Formal Scalar Types

1/2 {*AI95-00442-01*} A *formal scalar type* is one defined by any of the formal_type_definitions in this subclause. [The category determined for a formal scalar type is the category of all discrete, signed integer, modular, floating point, ordinary fixed point, or decimal types.]

1.a/2 **Proof:** {*AI95-00442-01*} The second rule follows from the rule in 12.5 that says that the category is determined by the one given in the name of the syntax production. The effect of the rule is repeated here to give a capsule summary of what this subclause is about.

1.b/2 **Ramification:** {*AI95-00442-01*} The “category of a type” includes any classes that the type belongs to.

Syntax

2 formal_discrete_type_definition ::= (<>)

3 formal_signed_integer_type_definition ::= **range** <>

4 formal_modular_type_definition ::= **mod** <>

5 formal_floating_point_definition ::= **digits** <>

6 formal_ordinary_fixed_point_definition ::= **delta** <>

7 formal_decimal_fixed_point_definition ::= **delta** <> **digits** <>

Legality Rules

8 The actual type for a formal scalar type shall not be a nonstandard numeric type.

8.a **Reason:** This restriction is necessary because nonstandard numeric types have some number of restrictions on their use, which could cause contract model problems in a generic body. Note that nonstandard numeric types can be passed to formal derived and formal private subtypes, assuming they obey all the other rules, and assuming the implementation allows it (being nonstandard means the implementation might disallow anything).

Wording Changes from Ada 95

{*AI95-00442-01*} We change to "determines a category" as that is the new terminology (it avoids confusion, since not all interesting properties form a class). 9.a/2

12.5.3 Formal Array Types

{*AI95-00442-01*} [The category determined for a formal array type is the category of all array types.] 1/2

Proof: {*AI95-00442-01*} This rule follows from the rule in 12.5 that says that the category is determined by the one given in the name of the syntax production. The effect of the rule is repeated here to give a capsule summary of what this subclause is about. 1.a/2

Syntax

formal_array_type_definition ::= array_type_definition 2

Legality Rules

The only form of discrete_subtype_definition that is allowed within the declaration of a generic formal (constrained) array subtype is a subtype_mark. 3

Reason: The reason is the same as for forbidding constraints in subtype_indications (see 12.1). 3.a

For a formal array subtype, the actual subtype shall satisfy the following conditions: 4

- The formal array type and the actual array type shall have the same dimensionality; the formal subtype and the actual subtype shall be either both constrained or both unconstrained. 5
- For each index position, the index types shall be the same, and the index subtypes (if unconstrained), or the index ranges (if constrained), shall statically match (see 4.9.1). 6
- The component subtypes of the formal and actual array types shall statically match. 7
- If the formal type has aliased components, then so shall the actual. 8

Ramification: On the other hand, if the formal's components are not aliased, then the actual's components can be either aliased or not. 8.a

Examples

Example of formal array types: 9

```
-- given the generic package                                                    10
generic                                                                         11
   type Item   is private;
   type Index  is (<>);
   type Vector is array (Index range <>) of Item;
   type Table  is array (Index) of Item;
package P is
   ...
end P;
-- and the types                                                                12
type Mix    is array (Color range <>) of Boolean;                               13
type Option is array (Color) of Boolean;
-- then Mix can match Vector and Option can match Table                         14
package R is new P(Item   => Boolean, Index => Color,                           15
                   Vector => Mix,     Table => Option);
-- Note that Mix cannot match Table and Option cannot match Vector              16
```

Incompatibilities With Ada 83

The check for matching of component subtypes and index subtypes or index ranges is changed from a runtime check to a compile-time check. The Ada 83 rule that "If the component type is not a scalar type, then the component subtypes 16.a

shall be either both constrained or both unconstrained" is removed, since it is subsumed by static matching. Likewise, the rules requiring that component types be the same is subsumed.

Wording Changes from Ada 95

16.b/2 {*AI95-00442-01*} We change to "determines a category" as that is the new terminology (it avoids confusion, since not all interesting properties form a class).

12.5.4 Formal Access Types

1/2 {*AI95-00442-01*} [The category determined for a formal access type is the category of all access types.]

1.a/2 **Proof:** {*AI95-00442-01*} This rule follows from the rule in 12.5 that says that the category is determined by the one given in the name of the syntax production. The effect of the rule is repeated here to give a capsule summary of what this subclause is about.

Syntax

2 formal_access_type_definition ::= access_type_definition

Legality Rules

3 For a formal access-to-object type, the designated subtypes of the formal and actual types shall statically match.

4/2 {*AI95-00231-01*} If and only if the general_access_modifier **constant** applies to the formal, the actual shall be an access-to-constant type. If the general_access_modifier **all** applies to the formal, then the actual shall be a general access-to-variable type (see 3.10). If and only if the formal subtype excludes null, the actual subtype shall exclude null.

4.a **Ramification:** If no _modifier applies to the formal, then the actual type may be either a pool-specific or a general access-to-variable type.

4.a.1/1 **Reason:** {*8652/0109*} {*AI95-00025-01*} Matching an access-to-variable to a formal access-to-constant type cannot be allowed. If it were allowed, it would be possible to create an access-to-variable value designating a constant.

4.b/2 {*AI95-00231-01*} We require that the "excludes null" property match, because it would be difficult to write a correct generic for a formal access type without knowing this property. Many typical algorithms and techniques will not work for a subtype that excludes null (setting an unused component to **null**, default-initialized objects, and so on). Even Ada.Unchecked_Deallocation would fail for a subtype that excludes null. Most generics would end up with comments saying that they are not intended to work for subtypes that exclude null. We would rather that this sort of requirement be reflected in the contract of the generic.

5/3 {*AI05-0239-1*} {*AI05-0288-1*} For a formal access-to-subprogram subtype, the designated profiles of the formal and the actual shall be subtype conformant.

Examples

6 *Example of formal access types:*

7
```
-- the formal types of the generic package
```

8
```
generic
   type Node is private;
   type Link is access Node;
package P is
   ...
end P;
```

9
```
-- can be matched by the actual types
```

10
```
type Car;
type Car_Name is access Car;
```

```
type Car is                                                                    11
   record
      Pred, Succ : Car_Name;
      Number     : License_Number;
      Owner      : Person;
   end record;
-- in the following generic instantiation                                      12
package R is new P(Node => Car, Link => Car_Name);                             13
```

Incompatibilities With Ada 83

The check for matching of designated subtypes is changed from a runtime check to a compile-time check. The Ada 83 rule that "If the designated type is other than a scalar type, then the designated subtypes shall be either both constrained or both unconstrained" is removed, since it is subsumed by static matching. 13.a

Extensions to Ada 83

Formal access-to-subprogram subtypes and formal general access types are new concepts. 13.b

Wording Changes from Ada 95

{*AI95-00231-01*} Added a matching rule for subtypes that exclude null. 13.c/2

{*AI95-00442-01*} We change to "determines a category" as that is the new terminology (it avoids confusion, since not all interesting properties form a class). 13.d/2

Incompatibilities With Ada 2005

{*AI05-0288-1*} **Correction:** Matching of formal access-to-subprogram types now uses subtype conformance rather than mode conformance, which is needed to plug a hole. This could cause some instantiations legal in Ada 95 and Ada 2005 to be rejected in Ada 2012. We believe that formal access-to-subprogram types occur rarely, and actuals that are not subtype conformant are rarer still, so this should not happen often. (In addition, one popular compiler has a bug that causes such instances to be rejected, so no code compiled with that compiler could have an incompatibility.) 13.e/3

12.5.5 Formal Interface Types

{*AI95-00251-01*} {*AI95-00442-01*} [The category determined for a formal interface type is the category of all interface types.] 1/2

Proof: {*AI95-00442-01*} This rule follows from the rule in 12.5 that says that the category is determined by the one given in the name of the syntax production. The effect of the rule is repeated here to give a capsule summary of what this subclause is about. 1.a/2

Ramification: Here we're taking advantage of our switch in terminology from "determined class" to "determined category"; by saying "category" rather than "class", we require that any actual type be an interface type, not just some type derived from an interface type. 1.b/2

Syntax

{*AI95-00251-01*} formal_interface_type_definition ::= interface_type_definition 2/2

Legality Rules

{*AI95-00251*} {*AI95-00401*} The actual type shall be a descendant of every progenitor of the formal type. 3/2

{*AI95-00345*} The actual type shall be a limited, task, protected, or synchronized interface if and only if the formal type is also, respectively, a limited, task, protected, or synchronized interface. 4/2

Discussion: We require the kind of interface type to match exactly because without that it is almost impossible to properly implement the interface. 4.a/2

Examples

5/5 *{AI12-0429-1} {AI12-0442-1} Example of the use of a generic with a formal interface type, to establish a standard interface that all tasks will implement so they can be managed appropriately by an application-specific scheduler:*

6/2
```
{AI95-00433-01} type Root_Work_Item is tagged private;
```

7/2
```
{AI95-00433-01} generic
   type Managed_Task is task interface;
   type Work_Item(<>) is new Root_Work_Item with private;
package Server_Manager is
   task type Server is new Managed_Task with
      entry Start(Data : in out Work_Item);
   end Server;
end Server_Manager;
```

Extensions to Ada 95

8.a/2 *{AI95-00251-01} {AI95-00345-01} {AI95-00401-01} {AI95-00442-01}* The formal interface type is new.

12.6 Formal Subprograms

1 [Formal subprograms can be used to pass callable entities to a generic unit.]

Language Design Principles

1.a Generic formal subprograms are like renames of the explicit_generic_actual_parameter.

Syntax

2/2 *{AI95-00260-02}* formal_subprogram_declaration ::= formal_concrete_subprogram_declaration
| formal_abstract_subprogram_declaration

2.1/3 *{AI95-00260-02} {AI05-0183-1}* formal_concrete_subprogram_declaration ::=
with subprogram_specification [**is** subprogram_default]
[aspect_specification];

2.2/3 *{AI95-00260-02} {AI05-0183-1}* formal_abstract_subprogram_declaration ::=
with subprogram_specification **is abstract** [subprogram_default]
[aspect_specification];

3/2 *{AI95-00348-01}* subprogram_default ::= default_name | <> | **null**

4 default_name ::= name

4.1/2 *{AI95-00260-02} {AI95-00348-01}* A subprogram_default of **null** shall not be specified for a formal function or for a formal_abstract_subprogram_declaration.

4.a/2 **Reason:** There are no null functions because the return value has to be constructed somehow. We don't allow null for abstract formal procedures, as the operation is dispatching. It doesn't seem appropriate (or useful) to say that the implementation of something is null in the formal type and all possible descendants of that type. This also would define a dispatching operation that doesn't correspond to a slot in the tag of the controlling type, which would be a new concept. Finally, additional rules would be needed to define the meaning of a dispatching null procedure (for instance, the convention of such a subprogram should be intrinsic, but that's not what the language says). It doesn't seem worth the effort.

Name Resolution Rules

5 The expected profile for the default_name, if any, is that of the formal subprogram.

5.a/3 **Ramification:** *{AI05-0299-1}* This rule, unlike others in this subclause, is observed at compile time of the generic_declaration.

The evaluation of the default_name takes place during the elaboration of each instantiation that uses the default, as defined in 12.3, "Generic Instantiation". 5.b

For a generic formal subprogram, the expected profile for the actual is that of the formal subprogram. 6

Legality Rules

{*AI05-0239-1*} The profiles of the formal and any named default shall be mode conformant. 7/3

Ramification: {*AI05-0299-1*} This rule, unlike others in this subclause, is checked at compile time of the generic_declaration. 7.a/3

{*AI05-0239-1*} The profiles of the formal and actual shall be mode conformant. 8/3

{*AI95-00423-01*} For a parameter or result subtype of a formal_subprogram_declaration that has an explicit null_exclusion: 8.1/2

- {*AI12-0183-1*} {*AI12-0287-1*} if the actual matching the formal_subprogram_declaration statically denotes a generic formal subprogram of another generic unit *G*, and the instantiation containing the actual occurs within the body of a generic unit *G* or within the body of a generic unit declared within the declarative region of the generic unit *G*, then the corresponding parameter or result type of the formal subprogram of *G* shall have a null_exclusion; 8.2/5
- otherwise, the subtype of the corresponding parameter or result type of the actual matching the formal_subprogram_declaration shall exclude null. In addition to the places where Legality Rules normally apply (see 12.3), this rule applies also in the private part of an instance of a generic unit. 8.3/2

Reason: This rule prevents "lying". **Null** must never be the value of a parameter or result with an explicit null_exclusion. The first bullet is an assume-the-worst rule which prevents trouble in generic bodies (including bodies of child generics) when the formal subtype excludes null implicitly. 8.a/2

{*AI12-0204-1*} If the named default, if any, is a prefixed view, the prefix of that view shall denote an object for which renaming is allowed (see 8.5.1). Similarly, if the actual subprogram in an instantiation is a prefixed view, the prefix of that view shall denote an object for which renaming is allowed. 8.4/5

Reason: {*AI12-0204-1*} The prefix in such a case is essentially renamed at the point of the instantiation and passed to any calls of the formal subprogram in the generic. If the prefix isn't legal to rename, that doesn't make sense (and allowing it might end up passing a nonexistent object to some calls). 8.b/5

{*AI95-00260-02*} {*AI05-0296-1*} If a formal parameter of a formal_abstract_subprogram_declaration is of a specific tagged type *T* or of an anonymous access type designating a specific tagged type *T*, *T* is called a *controlling type* of the formal_abstract_subprogram_declaration. Similarly, if the result of a formal_abstract_subprogram_declaration for a function is of a specific tagged type *T* or of an anonymous access type designating a specific tagged type *T*, *T* is called a controlling type of the formal_abstract_subprogram_declaration. A formal_abstract_subprogram_declaration shall have exactly one controlling type, and that type shall not be incomplete. 8.5/5

Ramification: The specific tagged type could be any of a formal tagged private type, a formal derived type, a formal interface type, or a normal tagged type. While the last case doesn't seem to be very useful, there isn't any good reason for disallowing it. This rule ensures that the operation is a dispatching operation of some type, and that we unambiguously know what that type is. 8.c/2

We informally call a subprogram declared by a formal_abstract_subprogram_declaration an *abstract formal subprogram*, but we do not use this term in normative wording. (We do use it often in these notes.) 8.d/2

{*AI95-00260-02*} {*AI12-0165-1*} The actual subprogram for a formal_abstract_subprogram_declaration shall be: 8.6/5

- a dispatching operation of the controlling type; or 8.7/5
- if the controlling type is a formal type, and the actual type corresponding to that formal type is a specific type *T*, a dispatching operation of type *T*; or 8.8/5

8.9/5 • if the controlling type is a formal type, and the actual type is a class-wide type *T*'Class, an implicitly declared subprogram corresponding to a primitive operation of type *T* (see Static Semantics below).

8.e/2 **To be honest:** We mean the controlling type of the formal_abstract_subprogram_declaration, of course. Saying that gets unwieldy and redundant (so says at least one reviewer, anyway).

8.e.1/5 **Ramification:** {*AI12-0165-1*} This means that the actual is a primitive operation of the controlling type, an abstract formal subprogram, or the implicitly available primitive operation for a class-wide type.

8.e.2/5 {*AI12-0165-1*} {*AI12-0005-1*} An explicit class-wide operation cannot be used for the actual of a formal abstract subprogram. Such an operation is never primitive (only specific types have primitive subprograms).

8.f/5 {*AI12-0165-1*} This could happen in a case like:

8.g/2
```
generic
   type T(<>) is tagged private;
   with procedure Foo (Obj : in T) is abstract;
package P ...
```

8.h/2
```
package New_P is new P (Something'Class, Some_Proc);
```

8.i/5 {*AI12-0165-1*} If Some_Proc is an explicit class-wide operation, the instantiation here is illegal, because Some_Proc is not a primitive operation of Something'Class (there are no such operations).

8.i.1/5 {*AI12-0165-1*} However, if Some_Proc is a primitive operation of type Something, then the instantiation is legal; the actual is the implicitly generated subprogram described in Static Semantics below. This is not a problem, since the rules given in 12.5.1 explain how this routine dispatches even though its parameter is class-wide.

8.i.2/5 {*AI12-0165-1*} We allow this special case because it is possible for a class-wide operation to be primitive inside of an instance, and the contract model does not allow us to make such cases illegal. As such, it seems inconsistent to not allow the same in explicit instantiations.

8.j/5 {*AI12-0005-1*} {*AI12-0165-1*} Specifically, since it is possible for a formal tagged type to be instantiated with a class-wide type, it is possible for the (real) controlling type to be class-wide as in the following unusual case:

8.k/5
```
{AI12-0005-1} generic
   type NT(<>) is new T with private;
   -- Presume that T has the following primitive operation:
   -- procedure Bar (Obj : in T);
package Gr ...
```

8.l/2
```
package body Gr is
   package New_P2 is new P (NT, Foo => Bar);
end Gr;
```

8.m/2
```
package New_Gr is new Gr (Something'Class);
```

8.n/5 {*AI12-0165-1*} The instantiation of New_P2 is legal, since Bar is a dispatching operation of the actual type of the controlling type of the abstract formal subprogram Foo. Again, the rules given in 12.5.1 explain how this routine dispatches.

8.o/2 Note that this legality rule never needs to be rechecked in an instance (that contains a nested instantiation). The rule only talks about the actual type of the instantiation; it does not require looking further; if the actual type is in fact a formal type, we do not intend looking at the actual for that formal.

Static Semantics

9 A formal_subprogram_declaration declares a generic formal subprogram. The types of the formal parameters and result, if any, of the formal subprogram are those determined by the subtype_marks given in the formal_subprogram_declaration; however, independent of the particular subtypes that are denoted by the subtype_marks, the nominal subtypes of the formal parameters and result, if any, are defined to be nonstatic, and unconstrained if of an array type [(no applicable index constraint is provided in a call on a formal subprogram)]. In an instance, a formal_subprogram_declaration declares a view of the actual. The profile of this view takes its subtypes and calling convention from the original profile of the actual entity, while taking the formal parameter names and default_expressions from the profile given in the formal_subprogram_declaration. The view is a function or procedure, never an entry.

9.a **Discussion:** This rule is intended to be the same as the one for renamings-as-declarations, where the formal_subprogram_declaration is analogous to a renaming-as-declaration, and the actual is analogous to the renamed view.

{*AI05-0071-1*} {*AI05-0131-1*} If a subtype_mark in the profile of the formal_subprogram_declaration denotes a formal private or formal derived type and the actual type for this formal type is a class-wide type *T*'Class, then for the purposes of resolving the corresponding actual subprogram at the point of the instantiation, certain implicit declarations may be available as possible resolutions as follows: 9.1/3

For each primitive subprogram of *T* that is directly visible at the point of the instantiation, and that has at least one controlling formal parameter, a corresponding implicitly declared subprogram with the same defining name, and having the same profile as the primitive subprogram except that *T* is systematically replaced by *T*'Class in the types of its profile, is potentially use-visible. The body of such a subprogram is as defined in 12.5.1 for primitive subprograms of a formal type when the actual type is class-wide. 9.2/3

Reason: {*AI05-0071-1*} {*AI05-0131-1*} This gives the same capabilities to formal subprograms as those that primitive operations of the formal type have when the actual type is class-wide. We do not want to discourage the use of explicit declarations for (formal) subprograms! 9.b/3

Implementation Note: {*AI05-0071-1*} {*AI05-0131-1*} Although the above wording seems to require constructing implicit versions of all of the primitive subprograms of type *T*, it should be clear that a compiler only needs to consider those that could possibly resolve to the corresponding actual subprogram. For instance, if the formal subprogram is a procedure with two parameters, and the actual subprogram name is Bar (either given explicitly or by default), the compiler need not consider primitives that are functions, that have the wrong number of parameters, that have defining names other than Bar, and so on; thus it does not need to construct implicit declarations for those primitives. 9.c/3

Ramification: {*AI05-0071-1*} {*AI05-0131-1*} Functions that only have a controlling result and do not have a controlling parameter of *T* are not covered by this rule, as any call would be required to raise Program_Error by 12.5.1. It is better to detect the error earlier than at run time. 9.d/3

If a generic unit has a subprogram_default specified by a box, and the corresponding actual parameter is omitted, then it is equivalent to an explicit actual parameter that is a usage name identical to the defining name of the formal. 10

{*AI95-00348-01*} If a generic unit has a subprogram_default specified by the reserved word **null**, and the corresponding actual parameter is omitted, then it is equivalent to an explicit actual parameter that is a null procedure having the profile given in the formal_subprogram_declaration. 10.1/2

{*AI95-00260-02*} The subprogram declared by a formal_abstract_subprogram_declaration with a controlling type *T* is a dispatching operation of type *T*. 10.2/2

Reason: This is necessary to trigger all of the dispatching operation rules. It otherwise would not be considered a dispatching operation, as formal subprograms are never primitive operations. 10.a/2

NOTE 1 {*AI12-0442-1*} The matching rules for formal subprograms state requirements that are similar to those applying to subprogram_renaming_declarations (see 8.5.4). In particular, the name of a parameter of the formal subprogram can be different from that of the corresponding parameter of the actual subprogram; similarly, for these parameters, default_expressions can be different. 11/5

NOTE 2 The constraints that apply to a parameter of a formal subprogram are those of the corresponding formal parameter of the matching actual subprogram (not those implied by the corresponding subtype_mark in the _specification of the formal subprogram). A similar remark applies to the result of a function. Therefore, to avoid confusion, it is recommended that the name of a first subtype be used in any declaration of a formal subprogram. 12

NOTE 3 The subtype specified for a formal parameter of a generic formal subprogram can be any visible subtype, including a generic formal subtype of the same generic_formal_part. 13

NOTE 4 A formal subprogram is matched by an attribute of a type if the attribute is a function with a matching specification. An enumeration literal of a given type matches a parameterless formal function whose result type is the given type. 14

NOTE 5 {*AI12-0347-1*} A default_name denotes an entity that is visible or directly visible at the place of the generic_declaration; a box used as a default is equivalent to a name that denotes an entity that is directly visible at the place of the generic_instantiation. 15/5

Proof: Visibility and name resolution are applied to the equivalent explicit actual parameter. 15.a

NOTE 6 {*AI95-00260-02*} The actual subprogram cannot be abstract unless the formal subprogram is a formal_abstract_subprogram_declaration (see 3.9.3). 16/2

16.1/5 NOTE 7 {*AI95-00260-02*} {*AI12-0442-1*} The subprogram declared by a formal_abstract_subprogram_declaration is an abstract subprogram. All calls on a subprogram declared by a formal_abstract_subprogram_declaration are limited to dispatching calls. See 3.9.3.

16.2/2 NOTE 8 {*AI95-00348-01*} A null procedure as a subprogram default has convention Intrinsic (see 6.3.1).

16.a.1/2 **Proof:** This is an implicitly declared subprogram, so it has convention Intrinsic as defined in 6.3.1.

Examples

17 *Examples of generic formal subprograms:*

18/2
```
{AI95-00433-01} with function "+"(X, Y : Item) return Item is <>;
with function Image(X : Enum) return String is Enum'Image;
with procedure Update is Default_Update;
with procedure Pre_Action(X : in Item) is null;  -- defaults to no action
with procedure Write(S    : not null access Root_Stream_Type'Class;
                     Desc : Descriptor)
                     is abstract Descriptor'Write;  -- see 13.13.2
-- Dispatching operation on Descriptor with default
```

19
```
-- given the generic procedure declaration
```

20
```
generic
   with procedure Action (X : in Item);
procedure Iterate(Seq : in Item_Sequence);
```

21
```
-- and the procedure
```

22
```
procedure Put_Item(X : in Item);
```

23
```
-- the following instantiation is possible
```

24
```
procedure Put_List is new Iterate(Action => Put_Item);
```

Extensions to Ada 95

24.a/2 {*AI95-00260-02*} The formal_abstract_subprogram_declaration is new. It allows the passing of dispatching operations to generic units.

24.b/2 {*AI95-00348-01*} The formal subprogram default of **null** is new. It allows the default of a generic procedure to do nothing, such as for passing a debugging routine.

Wording Changes from Ada 95

24.c/2 {*AI95-00423-01*} Added matching rules for null_exclusions.

Incompatibilities With Ada 2005

24.d/3 {*AI05-0296-1*} It is now illegal to declare a formal abstract subprogram whose controlling type is incomplete. It was never intended to allow that, and such a type would have to come from outside of the generic unit in Ada 2005, so it is unlikely to be useful. Moreover, a dispatching call on the subprogram is likely to fail in many implementations. So it is very unlikely that any code will need to be changed because of this new rule.

Extensions to Ada 2005

24.e/3 {*AI05-0071-1*} {*AI05-0131-1*} **Correction:** Added construction of implicit subprograms for primitives of class-wide actual types, to make it possible to import subprograms via formal subprograms as well as by implicit primitive operations of a formal type. (This is a **Correction** as it is very important for the usability of indefinite containers when instantiated with class-wide types; thus we want Ada 2005 implementations to support it.)

24.f/3 {*AI05-0183-1*} An optional aspect_specification can be used in a formal_concrete_subprogram_declaration and a formal_abstract_subprogram_declaration. This is described in 13.1.1.

Incompatibilities With Ada 2012

24.g/5 {*AI12-0204-1*} **Correction:** Added a rule to ensure that for an actual subprogram that is a prefixed view, the prefix continues to exist during the life of the instantiation. If the prefix is a subcomponent that depends on discriminants, Ada 2005 and 2012 would have allowed the prefix while Ada 2022 would not. Without this change, explicit forms (renaming the object and then using that in instantiations) would be safer than directly using the prefixed view; that's inconsistent with other kinds of actual subprograms.

Extensions to Ada 2012

{*AI12-0165-1*} **Correction:** We now allow the actual for a formal_abstract_subprogram_declaration to be an implicitly declared subprogram for a class-wide type. The rules already required a compiler to be able to construct this subprogram for use in an instantiation that occurs inside of a generic unit, so it made no sense to prevent it from being used explicitly as well (in the same way that the previous extension allows them to be used for other kinds of formal subprograms). 24.h/5

Wording Changes from Ada 2012

{*AI12-0287-1*} **Correction:** Added wording to ensure that the object subject to a Legality Rule can be determined at compile-time. The alternative being nonsense, we treat this as a wording change. 24.i/5

12.7 Formal Packages

[Formal packages can be used to pass packages to a generic unit. The formal_package_declaration declares that the formal package is an instance of a given generic package. Upon instantiation, the actual package has to be an instance of that generic package.] 1

Syntax

{*AI05-0183-1*} formal_package_declaration ::= 2/3
  with package defining_identifier **is new** *generic_package_*name formal_package_actual_part
    [aspect_specification];

{*AI95-00317-01*} formal_package_actual_part ::= 3/2
  ([**others** =>] <>)
 | [generic_actual_part]
 | (formal_package_association {, formal_package_association} [, **others** => <>])

{*AI95-00317-01*} formal_package_association ::= 3.1/2
  generic_association
 | *generic_formal_parameter_*selector_name => <>

{*AI95-00317-01*} Any positional formal_package_associations shall precede any named formal_-package_associations. 3.2/2

Legality Rules

The *generic_package_*name shall denote a generic package (the *template* for the formal package); the formal package is an instance of the template. 4

{*AI05-0025-1*} The *generic_formal_parameter_*selector_name of a formal_package_association shall denote a generic_formal_parameter_declaration of the template. If two or more formal subprograms of the template have the same defining name, then named associations are not allowed for the corresponding actuals. 4.1/3

{*AI95-00398-01*} A formal_package_actual_part shall contain at most one formal_package_association for each formal parameter. If the formal_package_actual_part does not include "**others** => <>", each formal parameter without an association shall have a default_expression or subprogram_default. 4.2/3

{*AI05-0200-1*} The rules for matching between formal_package_associations and the generic formals of the template are as follows: 4.3/3

- If all of the formal_package_associations are given by generic associations, the explicit_generic_actual_parameters of the formal_package_associations shall be legal for an instantiation of the template. 4.4/3

4.5/5 • {*AI05-0200-1*} If a formal_package_association for a formal type *T* of the template is given by <>, then the formal_package_association for any other generic_formal_parameter_declaration of the template that mentions *T* directly or indirectly shall also be given by <>.

4.a/3 **Discussion:** {*AI05-0200-1*} The above rule is simple to state, though it does not reflect the fact that the formal package functions like an instantiation of a special kind, where each box association for a generic_formal_parameter_declaration *F* is replaced with a new entity *F'* that has the same characteristics as *F*: if *F* is a formal discrete type then *F'* is a discrete type, if *F* is a formal subprogram then *F'* is a subprogram with a similar signature, etc. In practice this is achieved by making the association into a copy of the declaration of the generic formal.

5/2 {*AI95-00317-01*} The actual shall be an instance of the template. If the formal_package_actual_part is (<>) or (**others** => <>), [then the actual may be any instance of the template]; otherwise, certain of the actual parameters of the actual instance shall match the corresponding actual parameters of the formal package, determined as follows:

5.1/2 • {*AI95-00317-01*} If the formal_package_actual_part includes generic_associations as well as associations with <>, then only the actual parameters specified explicitly with generic_associations are required to match;

5.2/2 • {*AI95-00317-01*} Otherwise, all actual parameters shall match[, whether any actual parameter is given explicitly or by default].

5.3/2 {*AI95-00317-01*} The rules for matching of actual parameters between the actual instance and the formal package are as follows:

6/2 • {*AI95-00317-01*} For a formal object of mode **in**, the actuals match if they are static expressions with the same value, or if they statically denote the same constant, or if they are both the literal **null**.

6.a **Reason:** We can't simply require full conformance between the two actual parameter expressions, because the two expressions are being evaluated at different times.

7 • For a formal subtype, the actuals match if they denote statically matching subtypes.

8 • For other kinds of formals, the actuals match if they statically denote the same entity.

8.1/1 {*8652/0039*} {*AI95-00213-01*} For the purposes of matching, any actual parameter that is the name of a formal object of mode **in** is replaced by the formal object's actual expression (recursively).

Static Semantics

9 A formal_package_declaration declares a generic formal package.

10/2 {*AI95-00317-01*} The visible part of a formal package includes the first list of basic_declarative_items of the package_specification. In addition, for each actual parameter that is not required to match, a copy of the declaration of the corresponding formal parameter of the template is included in the visible part of the formal package. If the copied declaration is for a formal type, copies of the implicit declarations of the primitive subprograms of the formal type are also included in the visible part of the formal package.

10.a/2 **Ramification:** {*AI95-00317-01*} If the formal_package_actual_part is (<>), then the declarations that occur immediately within the generic_formal_part of the template for the formal package are visible outside the formal package, and can be denoted by expanded names outside the formal package. If only some of the actual parameters are given by <>, then the declaration corresponding to those parameters (but not the others) are made visible.

10.b/3 **Reason:** {*AI05-0005-1*} We always want either the actuals or the formals of an instance to be nameable from outside, but never both. If both were nameable, one would get some funny anomalies since they denote the same entity, but, in the case of types at least, they might have different and inconsistent sets of primitive operators due to predefined operator "reemergence", Formal derived types exacerbate the difference. We want the implicit declarations of the generic_formal_part as well as the explicit declarations, so we get operations on the formal types.

10.c **Ramification:** A generic formal package is a package, and is an instance. Hence, it is possible to pass a generic formal package as an actual to another generic formal package.

{*AI95-00317-01*} For the purposes of matching, if the actual instance *A* is itself a formal package, then the actual parameters of *A* are those specified explicitly or implicitly in the formal_package_actual_part for *A*, plus, for those not specified, the copies of the formal parameters of the template included in the visible part of *A*. 11/2

Examples

{*AI95-00433-01*} *Example of a generic package with formal package parameters:* 12/2

```
with Ada.Containers.Ordered_Maps;  -- see A.18.6                                13/2
generic
   with package Mapping_1 is new Ada.Containers.Ordered_Maps(<>);
   with package Mapping_2 is new Ada.Containers.Ordered_Maps
                                    (Key_Type => Mapping_1.Element_Type,
                                     others => <>);
package Ordered_Join is
   -- Provide a "join" between two mappings

   subtype Key_Type is Mapping_1.Key_Type;                                      14/2
   subtype Element_Type is Mapping_2.Element_Type;

   function Lookup(Key : Key_Type) return Element_Type;                         15/2

   ...                                                                          16/2
end Ordered_Join;
```

{*AI95-00433-01*} *Example of an instantiation of a package with formal packages:* 17/2

```
with Ada.Containers.Ordered_Maps;                                               18/2
package Symbol_Package is

{AI12-0178-1}    subtype Key_String is String(1..5);                            19/5
   type String_Id is ...

   type Symbol_Info is ...                                                      20/2

{AI12-0178-1}    package String_Table is new Ada.Containers.Ordered_Maps        21/5
           (Key_Type => Key_String,
            Element_Type => String_Id);

   package Symbol_Table is new Ada.Containers.Ordered_Maps                      22/2
           (Key_Type => String_Id,
            Element_Type => Symbol_Info);

   package String_Info is new Ordered_Join(Mapping_1 => String_Table,           23/2
                                           Mapping_2 => Symbol_Table);

   Apple_Info : constant Symbol_Info := String_Info.Lookup("Apple");            24/2

end Symbol_Package;                                                             25/2
```

Extensions to Ada 83

Formal packages are new to Ada 95. 25.a

Extensions to Ada 95

{*AI95-00317-01*} {*AI95-00398-01*} It's now allowed to mix actuals of a formal package that are specified with those that are not specified. 25.b/2

Wording Changes from Ada 95

{*8652/0039*} {*AI95-00213-01*} **Corrigendum:** Corrected the description of formal package matching to say that formal parameters are always replaced by their actual parameters (recursively). This matches the actual practice of compilers, as the ACATS has always required this behavior. 25.c/2

{*AI95-00317-01*} The description of which operations are visible in a formal package has been clarified. We also specify how matching is done when the actual is a formal package. 25.d/2

Incompatibilities With Ada 2005

{*AI05-0025-1*} {*AI05-0200-1*} **Correction:** Added missing rules for parameters of generic formal package that parallel those in 12.3, as well as some specific to <> parameters. These are technically incompatibilities because generic formal 25.e/3

package parameters that Ada 95 and Ada 2005 would have considered legal now have to be rejected. But this should not be an issue in practice as such formal parameters could not have matched any actual generics. And it is quite likely that implementations already enforce some of these rules.

Extensions to Ada 2005

25.f/3 {*AI05-0183-1*} An optional aspect_specification can be used in a formal_package_declaration. This is described in 13.1.1.

12.8 Example of a Generic Package

Examples

1 The following example provides a possible formulation of stacks by means of a generic package. The size of each stack and the type of the stack elements are provided as generic formal parameters.

2/1 *This paragraph was deleted.*

3
```
generic
   Size : Positive;
   type Item is private;
package Stack is
   procedure Push(E : in  Item);
   procedure Pop (E : out Item);
   Overflow, Underflow : exception;
end Stack;
```

4
```
package body Stack is
```

5
```
   type Table is array (Positive range <>) of Item;
   Space : Table(1 .. Size);
   Index : Natural := 0;
```

6
```
   procedure Push(E : in Item) is
   begin
      if Index >= Size then
         raise Overflow;
      end if;
      Index := Index + 1;
      Space(Index) := E;
   end Push;
```

7
```
   procedure Pop(E : out Item) is
   begin
      if Index = 0 then
         raise Underflow;
      end if;
      E := Space(Index);
      Index := Index - 1;
   end Pop;
```

8
```
end Stack;
```

9 Instances of this generic package can be obtained as follows:

10
```
package Stack_Int  is new Stack(Size => 200, Item => Integer);
package Stack_Bool is new Stack(100, Boolean);
```

11 Thereafter, the procedures of the instantiated packages can be called as follows:

12
```
Stack_Int.Push(N);
Stack_Bool.Push(True);
```

Alternatively, a generic formulation of the type Stack can be given as follows (package body omitted): 13

```
generic                                                                    14
   type Item is private;
package On_Stacks is
   type Stack(Size : Positive) is limited private;
   procedure Push(S : in out Stack; E : in  Item);
   procedure Pop (S : in out Stack; E : out Item);
   Overflow, Underflow : exception;
private
   type Table is array (Positive range <>) of Item;
   type Stack(Size : Positive) is
      record
         Space : Table(1 .. Size);
         Index : Natural := 0;
      end record;
end On_Stacks;
```

In order to use such a package, an instance has to be created and thereafter stacks of the corresponding type can be declared: 15

```
declare                                                                    16
   package Stack_Real is new On_Stacks(Real); use Stack_Real;
   S : Stack(100);
begin
   ...
   Push(S, 2.54);
   ...
end;
```

13 Representation Issues

{*8652/0009*} {*AI95-00137-01*} {*AI05-0299-1*} [This clause describes features for querying and controlling certain aspects of entities and for interfacing to hardware.] 1/3

Wording Changes from Ada 83

{*AI05-0299-1*} The subclauses of this clause have been reorganized. This was necessary to preserve a logical order, given the new Ada 95 semantics given in this section. 1.a/3

13.1 Operational and Representation Aspects

{*8652/0009*} {*AI95-00137-01*} {*AI05-0295-1*} [Two kinds of aspects of entities can be specified: representation aspects and operational aspects. Representation aspects affect how the types and other entities of the language are to be mapped onto the underlying machine. Operational aspects determine other properties of entities.] 0.1/3

Term entry: operational aspect — aspect that indicates a logical property of an entity, such as the precondition of a subprogram, or the procedure used to write a given type of object to a stream 0.a/5

Term entry: representation aspect — aspect that indicates how an entity is mapped onto the underlying hardware, for example the size or alignment of an object 0.b/5

{*AI05-0183-1*} {*AI05-0295-1*} [Either kind of aspect of an entity may be specified by means of an aspect_specification (see 13.1.1), which is an optional element of most kinds of declarations and applies to the entity or entities being declared. Aspects may also be specified by certain other constructs occurring subsequent to the declaration of the affected entity: a representation aspect value may be specified by means of a representation item and an operational aspect value may be specified by means of an operational item.] 0.2/3

{*8652/0009*} {*AI95-00137-01*} There are six kinds of *representation items*: attribute_definition_clauses for representation attributes, enumeration_representation_clauses, record_representation_clauses, at_clauses, component_clauses, and *representation pragmas*. [They can be provided to give more efficient representation or to interface with features that are outside the domain of the language (for example, peripheral hardware).] 1/1

{*8652/0009*} {*AI95-00137-01*} An *operational item* is an attribute_definition_clause for an operational attribute. 1.1/1

{*8652/0009*} {*AI95-00137-01*} [An operational item or a representation item applies to an entity identified by a local_name, which denotes an entity declared local to the current declarative region, or a library unit declared immediately preceding a representation pragma in a compilation.] 1.2/1

Language Design Principles

{*8652/0009*} {*AI95-00137-01*} {*AI05-0295-1*} Representation aspects are intended to refer to properties that need to be known before the compiler can generate code to create or access an entity. For instance, the size of an object needs to be known before the object can be created. Conversely, operational aspects are those that only need to be known before they can be used. For instance, how an object is read from a stream only needs to be known when a stream read is executed. Thus, representation aspects have stricter rules as to when they can be specified. 1.a/3

{*AI95-00291-02*} {*AI05-0295-1*} Confirming the value of an aspect should never change the semantics of the aspect. Thus Size = 8 (for example) means the same thing whether it was specified with a representation item or whether the compiler chose this value by default. 1.a.1/3

Term entry: aspect — specifiable property of an entity 1.b/5
Note: An aspect can be specified by an aspect_specification on the declaration of the entity. Some aspects can be queried via attributes.

Syntax

2/1 {*8652/0009*} {*AI95-00137-01*} aspect_clause ::= attribute_definition_clause
| enumeration_representation_clause
| record_representation_clause
| at_clause

3 local_name ::= direct_name
| direct_name'attribute_designator
| *library_unit*_name

4/1 {*8652/0009*} {*AI95-00137-01*} A representation pragma is allowed only at places where an aspect_clause or compilation_unit is allowed.

Name Resolution Rules

5/1 {*8652/0009*} {*AI95-00137-01*} In an operational item or representation item, if the local_name is a direct_name, then it shall resolve to denote a declaration (or, in the case of a pragma, one or more declarations) that occurs immediately within the same declarative region as the item. If the local_name has an attribute_designator, then it shall resolve to denote an implementation-defined component (see 13.5.1) or a class-wide type implicitly declared immediately within the same declarative region as the item. A local_name that is a *library_unit*_name (only permitted in a representation pragma) shall resolve to denote the library_item that immediately precedes (except for other pragmas) the representation pragma.

5.a/1 **Reason:** {*8652/0009*} {*AI95-00137-01*} This is a Name Resolution Rule, because we don't want an operational or representation item for X to be ambiguous just because there's another X declared in an outer declarative region. It doesn't make much difference, since most operational or representation items are for types or subtypes, and type and subtype names can't be overloaded.

5.b/1 **Ramification:** {*8652/0009*} {*AI95-00137-01*} The visibility rules imply that the declaration has to occur before the operational or representation item.

5.c/1 {*8652/0009*} {*AI95-00137-01*} For objects, this implies that operational or representation items can be applied only to stand-alone objects.

Legality Rules

6/1 {*8652/0009*} {*AI95-00137-01*} The local_name of an aspect_clause or representation pragma shall statically denote an entity (or, in the case of a pragma, one or more entities) declared immediately preceding it in a compilation, or within the same declarative_part, package_specification, task_definition, protected_definition, or record_definition as the representation or operational item. If a local_name denotes a [local] callable entity, it may do so through a [local] subprogram_renaming_declaration [(as a way to resolve ambiguity in the presence of overloading)]; otherwise, the local_name shall not denote a renaming_declaration.

6.a **Ramification:** The “statically denote” part implies that it is impossible to specify the representation of an object that is not a stand-alone object, except in the case of a representation item like pragma Atomic that is allowed inside a component_list (in which case the representation item specifies the representation of components of all objects of the type). It also prevents the problem of renamings of things like “P.**all**” (where P is an access-to-subprogram value) or “E(I)” (where E is an entry family).

6.b The part about where the denoted entity has to have been declared appears twice — once as a Name Resolution Rule, and once as a Legality Rule. Suppose P renames Q, and we have a representation item in a declarative_part whose local_name is P. The fact that the representation item has to appear in the same declarative_part as P is a Name Resolution Rule, whereas the fact that the representation item has to appear in the same declarative_part as Q is a Legality Rule. This is subtle, but it seems like the least confusing set of rules.

6.c **Discussion:** A separate Legality Rule applies for component_clauses. See 13.5.1, “Record Representation Clauses”.

7/5 {*AI95-00291-02*} {*AI12-0445-1*} The *representation* of an object consists of a certain number of bits (the *size* of the object). For an object of an elementary type, these are the bits that are normally read or

updated by the machine code when loading, storing, or operating-on the value of the object. For an object of a composite type, these are the bits reserved for this object, and include bits occupied by subcomponents of the object. If the size of an object is greater than that of its subtype, the additional bits are padding bits. For an elementary object, these padding bits are normally read and updated along with the others. For a composite object, it is unspecified whether padding bits are read or updated in any given composite operation.

To be honest: {*AI95-00291-02*} Discontiguous representations are allowed, but the ones we're interested in here are generally contiguous sequences of bits. For a discontiguous representation, the size doesn't necessarily describe the "footprint" of the object in memory (that is, the amount of space taken in the address space for the object). 7.a/2

Discussion: {*AI95-00291-02*} In the case of composite objects, we want the implementation to have the flexibility to either do operations component-by-component, or with a block operation covering all of the bits. We carefully avoid giving a preference in the wording. There is no requirement for the choice to be documented, either, as the implementation can make that choice based on many factors, and could make a different choice for different operations on the same object. 7.a.1/2

{*AI95-00291-02*} In the case of a properly aligned, contiguous object whose size is a multiple of the storage unit size, no other bits should be read or updated as part of operating on the object. We don't say this normatively because it would be difficult to normatively define "properly aligned" or "contiguous". 7.a.2/2

Ramification: Two objects with the same value do not necessarily have the same representation. For example, an implementation might represent False as zero and True as any odd value. Similarly, two objects (of the same type) with the same sequence of bits do not necessarily have the same value. For example, an implementation might use a biased representation in some cases but not others: 7.b

```
{AI05-0229-1} subtype S is Integer range 1..256;                    7.c/3
type A is array(Natural range 1..4) of S
   with Pack;
X : S := 3;
Y : A := (1, 2, 3, 4);
```

The implementation might use a biased-by-1 representation for the array elements, but not for X. X and Y(3) have the same value, but different representation: the representation of X is a sequence of (say) 32 bits: 0...011, whereas the representation of Y(3) is a sequence of 8 bits: 00000010 (assuming a two's complement representation). 7.d

Such tricks are not required, but are allowed. 7.e

Discussion: The value of any padding bits is not specified by the language, though for a numeric type, it will be much harder to properly implement the predefined operations if the padding bits are not either all zero, or a sign extension. 7.f

Ramification: {*AI05-0229-1*} For example, suppose S'Size = 2, and an object X is of subtype S. If the machine code typically uses a 32-bit load instruction to load the value of X, then X'Size should be 32, even though 30 bits of the value are just zeros or sign-extension bits. On the other hand, if the machine code typically masks out those 30 bits, then X'Size should be 2. Usually, such masking only happens for components of a composite type for which Pack, Component_Size, or record layout is specified. 7.g/3

Note, however, that the formal parameter of an instance of Unchecked_Conversion is a special case. Its Size is required to be the same as that of its subtype. 7.h

Note that we don't generally talk about the representation of a value. A value is considered to be an amorphous blob without any particular representation. An object is considered to be more concrete. 7.i

{*AI05-0112-1*} {*AI05-0295-1*} {*AI12-0396-1*} {*AI12-0407-1*} A representation item *directly specifies* a *representation aspect* of the entity denoted by the local_name, except in the case of a type-related representation item, whose local_name shall denote a first subtype, and which directly specifies an aspect of the subtype's type. A representation item that names a subtype is either *subtype-specific* (Size, Object_Size, and Alignment clauses) or *type-related* (all others). 8/5

This paragraph was deleted.{*AI12-0407-1*} 8.a/5

To be honest: Some representation items directly specify more than one aspect. 8.b

Discussion: {*AI05-0229-1*} For example, a pragma Export (see J.15.5) specifies the convention of an entity, and also specifies that it is exported. Such items are obsolescent; directly specifying the associated aspects is preferred. 8.c/3

Ramification: Each specifiable attribute constitutes a separate aspect. An enumeration_representation_clause specifies the coding aspect. A record_representation_clause (without the mod_clause) specifies the record layout aspect. Each representation pragma specifies a separate aspect. 8.d

8.e **Reason:** We don't need to say that an at_clause or a mod_clause specify separate aspects, because these are equivalent to attribute_definition_clauses. See J.7, “At Clauses”, and J.8, “Mod Clauses”.

8.e.1/3 {*AI05-0112-1*} We give a default naming for representation aspects of representation pragmas so we don't have to do that for every pragma. Operational and representation attributes are given a default naming in 13.3. We don't want any anonymous aspects; that would make other rules more difficult to write and understand.

8.f **Ramification:** The following representation items are type-related:

8.g • enumeration_representation_clause

8.h • record_representation_clause

8.i • Component_Size clause

8.j/1 • *This paragraph was deleted.*{*8652/0009*} {*AI95-00137-01*}

8.k • Small clause

8.l • Bit_Order clause

8.m • Storage_Pool clause

8.n • Storage_Size clause

8.o/2 • {*8652/0009*} {*AI95-00137-01*} {*AI95-00270-01*} Stream_Size clause

8.p/5 • {*8652/0009*} {*AI95-00137-01*} {*AI12-0005-1*} pragma Unchecked_Union

8.q/1 • *This paragraph was deleted.*{*8652/0009*} {*AI95-00137-01*}

8.r/1 • *This paragraph was deleted.*{*8652/0009*} {*AI95-00137-01*}

8.s • Machine_Radix clause

8.t • pragma Pack

8.u • pragmas Import, Export, and Convention (when applied to a type)

8.v/3 • {*AI05-0009-1*} pragmas Atomic, Independent, and Volatile (when applied to a type)

8.w/3 • {*AI05-0009-1*} pragmas Atomic_Components, Independent_Components, and Volatile_Components (when applied to a type)

8.x • pragma Discard_Names (when applied to an enumeration or tagged type)

8.x.1/5 • {*AI12-0005-1*} pragmas Priority and Interrupt_Priority (when applied to a task or protected type)

8.x.2/5 • {*AI12-0005-1*} pragma CPU (when applied to a task or protected type)

8.x.3/5 • {*AI12-0005-1*} pragma Dispatching_Domain

8.x.4/5 • {*AI12-0005-1*} pragma Relative_Deadline (when applied to a task or protected type)

8.y The following representation items are subtype-specific:

8.z • Alignment clause (when applied to a first subtype)

8.z.1/5 • {*AI12-0396-1*} Object_Size clause

8.aa • Size clause (when applied to a first subtype)

8.bb The following representation items do not apply to subtypes, so they are neither type-related nor subtype-specific:

8.cc • Address clause (applies to objects and program units)

8.dd • Alignment clause (when applied to an object)

8.ee • Size clause (when applied to an object)

8.ff/2 • {*AI95-00414-01*} pragma Inline (applies to subprograms)

8.gg • pragmas Import, Export, and Convention (when applied to anything other than a type)

8.hh • pragmas Atomic and Volatile (when applied to an object or a component)

8.ii/3 • {*AI05-0009-1*} pragmas Atomic_Components, Independent_Components, and Volatile_Components (when applied to an array object)

8.jj • pragma Discard_Names (when applied to an exception)

8.kk • pragma Asynchronous (applies to procedures)

8.ll/2 • {*AI95-00414-01*} pragma No_Return (applies to subprograms)

8.ll.1/5 • {*AI12-0005-1*} pragmas Attach_Handler and Interrupt_Handler (apply to protected units)

8.ll.2/5 • {*AI12-0005-1*} pragmas Priority and Interrupt_Priority (when applied to a subprogram)

8.ll.3/5 • {*AI12-0005-1*} pragma CPU (when applied to a subprogram)

- {*AI12-0005-1*} pragma Relative_Deadline (when applied to a subprogram) 8.ll.4/5

{*AI05-0229-1*} {*AI12-0005-1*} While an aspect_specification is not a representation item, a similar categorization applies to the aspect that corresponds to each of these representation items. In addition, there are representation aspects that do not have associated representation items. 8.mm/5

{*AI12-0005-1*} The following representation aspects that do not have associated representation items are type-related: 8.mm.1/5

- aspect Default_Value 8.mm.2/5
- aspect Default_Component_Value 8.mm.3/5
- aspect Exclusive_Functions 8.mm.4/5
- aspects Link_Name and External_Name (when applied to a type) 8.mm.5/5
- aspect Max_Entry_Queue_Length (when applied to a task or protected type) 8.mm.6/5

{*AI12-0005-1*} There are no subtype-specific representation aspects that do not have associated representation items. 8.mm.7/5

{*AI12-0005-1*} The following representation aspects that do not have associated representation items also do not apply to subtypes, so they are neither type-related nor subtype-specific: 8.mm.8/5

- aspect Static (applies to expression functions) 8.mm.9/5
- aspect Synchronization (applies to procedures) 8.mm.10/5
- aspects Link_Name and External_Name (when applied to anything other than a type) 8.mm.11/5
- aspect Max_Entry_Queue_Length (when applied to an entry) 8.mm.12/5

{*8652/0009*} {*AI95-00137-01*} {*AI05-0183-1*} An operational item *directly specifies* an *operational aspect* of the entity denoted by the local_name, except in the case of a type-related operational item, whose local_name shall denote a first subtype, and which directly specifies an aspect of the type of the subtype. 8.1/3

Ramification: {*8652/0009*} {*AI95-00137-01*} The following operational items are type-related: 8.nn/1

- External_Tag clause 8.oo/1
- Read clause 8.pp/1
- Write clause 8.qq/1
- Input clause 8.rr/1
- Output clause 8.ss/1

{*AI12-0407-1*} Aspects that can be specified for types and subtypes are also classified into type-related or subtype-specific aspects. Representation aspects that can be specified for types and subtypes are considered type-related unless specified otherwise. In contrast, the classification of operational aspects are given with the definition of the aspect. Type-related aspects have the same value for all subtypes of (a view of) a type[, while subtype-specific aspects may differ for different subtypes of the same type]. 8.2/5

Discussion: We talk about “type-related aspects”, which of course include both type-related representation aspects and type-related operational aspects. Aspects Size, Object_Size, and Alignment are subtype-specific, as that is specified above. All other representation aspects are either type-related or not specifiable for a type or subtype. Unlike representation aspects, there is no default for operational aspects; whether they are type-related or subtype-specific should be part of the definition of the aspect. 8.tt/5

{*AI05-0183-1*} {*AI12-0116-1*} {*AI12-0181-1*} {*AI12-0222-1*} A representation item or operational item that directly specifies an aspect of an entity shall appear before the entity is frozen (see 13.14). 9/5

Ramification: {*8652/0009*} {*AI95-00137-01*} {*AI12-0222-1*} The fact that a representation item (or operational item) that directly specifies an aspect of an entity is required to appear before the entity is frozen prevents changing the representation of an entity after using the entity in ways that require the representation to be known. 9.a/5

This paragraph was deleted.{*AI05-0183-1*} {*AI12-0116-1*} 9.b/4

{*8652/0009*} {*AI95-00137-01*} {*AI05-0183-1*} {*AI12-0116-1*} {*AI12-0222-1*} A representation aspect of a subtype or type shall not be specified (whether by a representation item or an aspect_specification) before the type is completely defined (see 3.11.1). 9.1/5

Ramification: Unlike representation items, operational items can be specified on partial views. Since they don't affect the representation, the full declaration need not be known to determine their legality. 9.c/1

9.2/5 {*AI12-0116-1*} {*AI12-0396-1*} {*AI12-0417-1*} If a representation item, operational item, library unit pragma (see J.15), or aspect_specification is given that directly specifies an aspect of an entity, then it is illegal to give another representation item, operational item, library unit pragma, or aspect_specification that directly specifies the same aspect of the entity.

9.c.1/5 **Ramification:** {*AI12-0116-1*} {*AI12-0396-1*} This rule applies to all aspects, not just those that have operational items or representation items. For instance, it applies to subtype predicates and type invariants.

9.c.2/4 **To be honest:** {*AI12-0116-1*} This rule is also intended to cover other ways to specify representation aspects, such as obsolescent pragma Priority. Priority is not a representation pragma, and as such is neither a representation item nor an aspect_specification. Regardless, giving both a pragma Priority and an aspect_specification for Priority is illegal. We didn't want to complicate the wording solely to support obsolescent features.

9.3/5 {*AI05-0106-1*} {*AI05-0295-1*} {*AI12-0116-1*} {*AI12-0181-1*} Unless otherwise specified, it is illegal to specify an operational or representation aspect of a generic formal parameter.

9.d/5 **Reason:** {*AI12-0064-2*} Specifying an aspect on a generic formal parameter implies an added contract for a generic unit. That contract needs to be defined via generic parameter matching rules, and, as aspects vary widely, that has to be done for each such aspect. Since most aspects do not need this complexity, we avoid the complexity by saying that such contract-forming aspect specifications are banned unless the rules defining them explicitly exist. Note that the method of specification does not matter: aspect_specifications, representation items, and operational items are all covered by this rule.

10/5 {*AI05-0295-1*} {*AI12-0109-1*} {*AI12-0376-1*} {*AI12-0427-1*} A *by-reference primitive* is a user-defined primitive subprogram for a type *T* that has an access result designating type *T*, or that has a formal parameter that is an access parameter designating type *T* or is aliased and of type *T*. It is illegal to specify a nonconfirming type-related representation aspect for an untagged type *T* if it is derived from a by-reference type or inherits one or more by-reference primitives, or if one or more types have been derived from *T* prior to the specification of the aspect and type *T* is a by-reference type or defines one or more by-reference primitives that are inherited by these descendants.

10.a/3 **Ramification:** {*8652/0009*} {*AI95-00137-01*} {*AI05-0295-1*} On the other hand, subtype-specific representation aspects may be specified for the first subtype of such a type, as can operational aspects.

10.b/5 **Reason:** {*AI05-0229-1*} {*AI05-0295-1*} {*AI12-0109-1*} {*AI12-0376-1*} {*AI12-0427-1*} The reason for forbidding specification of type-related representation aspects on untagged by-reference types is because a change of representation is impossible when passing by reference (to an inherited subprogram). (A by-reference object cannot be copied to change its representation.) The reason for forbidding specification of type-related representation aspects on untagged types with by-reference primitives is that access parameters, access results, and aliased parameters cannot be converted as part of invoking an inherited subprogram if the representation of the designated types might be different. This rule is not needed for tagged types, because other rules prevent a type-related representation aspect from changing the representation of the parent part; we want to allow specifying a type-related representation aspect on a type extension to specify aspects of the extension part. For example, specifying aspect Pack will cause packing of the extension part, but not of the parent part.

10.c/4 **Discussion:** {*AI12-0109-1*} "By-reference type" usually cannot be used in Legality Rules, as it is privacy breaking. Our use here is privacy breaking, but we're stuck with it for compatibility reasons. Since representation aspects cannot be specified on partial views, privacy violations only can happen when a type includes a component of a private type. In that case, whether these rules are triggered depends on the full type of the private type — which is clearly privacy breaking.

11/5 {*8652/0009*} {*AI95-00137-01*} {*8652/0011*} {*AI95-00117-01*} {*AI95-00326-01*} {*AI05-0295-1*} {*AI12-0396-1*} {*AI12-0409-1*} If a type-related aspect is defined for the partial view of a type, then it has the same definition for the full view of the type, except for certain Boolean-valued operational aspects where the language specifies that the partial view can have the value False even when the full view has the value True. Type-related aspects [cannot be specified, and] are not defined for an incomplete view of a type. Representation aspects of a generic formal parameter are the same as those of the actual. Specification of a type-related representation aspect is not allowed for a descendant of a generic formal untagged type.

11.a/3 **Ramification:** {*8652/0009*} {*AI95-00137-01*} {*AI05-0295-1*} Specifying representation aspects is allowed for types whose subcomponent types or index subtypes are generic formal types. Specifying operational aspects and subtype-related representation aspects is allowed on descendants of generic formal types.

Reason: {*AI05-0295-1*} Since it is not known whether a formal type has user-defined primitive subprograms, specifying type-related representation aspects for them is not allowed, unless they are tagged (in which case only the extension part is affected in any case). 11.b/3

This paragraph was deleted.{*AI95-00326-01*} {*AI12-0396-1*} 11.c/5

Ramification: {*AI05-0083-1*} {*AI12-0396-1*} Different views of an entity can have different representation and operational aspects. Most type-related aspects are the same for all views of a type; but specific aspects may have different rules. Similarly, different views of an object can have different representation aspects. For instance, an actual object passed by reference and the associated formal parameter may have different values for Alignment even though the formal parameter is merely a view of the actual object. This is necessary to maintain the language design principle that Alignments are always known at compile time. 11.d/5

Discussion: {*AI12-0409-1*} For type-related aspects, the aspect of the partial view (if any) and full view have to be the same, with an exception for certain Boolean-valued aspects. The exception is intended for aspect Preelaborable_Initialization, where it would be wildly incompatible (as well as unfriendly) to require the (possibly implicit) state of the full view to be repeated explicitly on the partial view. Aspect Nonblocking has a similar rule for similar reasons, though it is a subtype-specific aspect. 11.e/5

Proof: {*AI12-0396-1*} The syntax of incomplete_type_declarations and formal_incomplete_type_declarations do not allow for an aspect_specification. The prefix of an attribute_reference cannot name an incomplete type (see 3.10.1), so no attribute_definition_clause can be used with an incomplete type. Similarly, the local_name of a representation pragma cannot name an incomplete type, so no such pragmas can be used with an incomplete type. 11.f/5

{*AI05-0295-1*} The specification of the Size aspect for a given subtype, or the size or storage place for an object (including a component) of a given subtype, shall allow for enough storage space to accommodate any value of the subtype. 12/3

{*8652/0009*} {*AI95-00137-01*} {*AI05-0295-1*} {*AI12-0396-1*} {*AI12-0444-1*} The specification of certain language-defined aspects is not required to be supported by all implementations; in such an implementation, the specification for such an aspect is illegal or raises an exception at run time. 13/5

Ramification: There is an Implementation Permission below that allows an implementation to put restrictions on any representation aspect; this rule applies if that permission is used for an aspect. This rule only applies to an operational aspect if the aspect explicitly allows the aspect to not be supported. 13.a

{*AI95-00251-01*} {*AI05-0295-1*} A type_declaration is illegal if it has one or more progenitors, and a nonconfirming value was specified for a representation aspect of an ancestor, and this conflicts with the representation of some other ancestor. The cases that cause conflicts are implementation defined. 13.1/3

Implementation defined: The cases that cause conflicts between the representation of the ancestors of a type_declaration. 13.b/2

Reason: {*AI05-0295-1*} This rule is needed because it may be the case that only the combination of types in a type declaration causes a conflict. Thus it is not possible, in general, to reject the original representation item or aspect_specification. For instance: 13.c/3

```
package Pkg1 is                                                    13.d/2
   type Ifc is interface;
   type T is tagged record
      Fld : Integer;
   end record;
   for T use record
      Fld at 0 range 0 .. Integer'Size - 1;
   end record;
end Pkg1;
```

Assume the implementation uses a single tag with a default offset of zero, and that it allows the use of nondefault locations for the tag (and thus accepts representation items like the one above). The representation item will force a nondefault location for the tag (by putting a component other than the tag into the default location). Clearly, this package will be accepted by the implementation. However, other declarations could cause trouble. For instance, the implementation could reject: 13.e/2

```
with Pkg1;                                                         13.f/2
package Pkg2 is
   type NewT is new Pkg1.T and Pkg1.Ifc with null record;
end Pkg2;
```

{*AI05-0295-1*} because the declarations of T and Ifc have a conflict in their representation items. This is clearly necessary (it's hard to imagine how Ifc'Class could work with the tag at a location other than the one it is expecting without introducing distributed overhead). 13.g/3

13.h/3 {*AI05-0295-1*} Conflicts will usually involve implementation-defined attributes (for specifying the location of the tag, for instance), although the example above shows that doesn't have to be the case. For this reason, we didn't try to specify exactly what causes a conflict; it will depend on the implementation's implementation model and what representation aspects it allows to be changed.

13.i/3 **Implementation Note:** {*AI05-0295-1*} An implementation can only use this rule to reject type_declarations where one of its ancestors had a nonconfirming representation value specified. An implementation must ensure that the default representations of ancestors cannot conflict.

13.2/5 {*AI12-0427-1*} When specifying an aspect that denotes a subprogram, the profile of the subprogram shall be mode conformant with the one required for the aspect, and the convention shall be Ada. Additional requirements are defined for particular aspects.

13.j/5 **Ramification:** As well as applying to aspect_specifications, this rule applies to attribute_definition_clauses for those aspects that have associated attributes.

13.k/5 This rule implies, for example, that if one writes:

13.l/5
```
type T is ...
   with Read => R;
```

13.m/5 R has to be a procedure with two parameters with the appropriate subtypes and modes as shown in 13.13.2.

Static Semantics

14/5 {*AI12-0059-1*} If two subtypes statically match, then their subtype-specific aspects (for example, Size and Alignment) are the same.

14.a/5 **Reason:** {*AI05-0295-1*} {*AI12-0059-1*} This is necessary because we allow (for example) conversion between access types whose designated subtypes statically match. Note that most aspects (including the subtype-specific aspects Size and Alignment) may not be specified for a nonfirst subtype. The only language-defined exceptions to this rule are the Object_Size, Static_Predicate, and Dynamic_Predicate aspects.

14.b Consider, for example:

14.c/5
```
{AI12-0005-1} package P1 is
   subtype S1 is Integer range 0..2**16-1
      with Size => 16; -- Illegal!
      -- S1'Size would be 16 by default.
   type A1 is access all S1;
   X1: A1;
end P1;
```

14.d/5
```
{AI12-0005-1} package P2 is
   subtype S2 is Integer range 0..2**16-1
      with Size => 32; -- Illegal!
   type A2 is access all S2;
   X2: A2;
end P2;
```

14.e/3
```
{AI05-0229-1} procedure Q is
   use P1, P2;
   type Array1 is array(Integer range <>) of aliased S1
      with Pack;
   Obj1: Array1(1..100);
   type Array2 is array(Integer range <>) of aliased S2
      with Pack;
   Obj2: Array2(1..100);
begin
   X1 := Obj2(17)'Unchecked_Access;
   X2 := Obj1(17)'Unchecked_Access;
end Q;
```

14.f Loads and stores through X1 would read and write 16 bits, but X1 points to a 32-bit location. Depending on the endianness of the machine, loads might load the wrong 16 bits. Stores would fail to zero the other half in any case.

14.g Loads and stores through X2 would read and write 32 bits, but X2 points to a 16-bit location. Thus, adjacent memory locations would be trashed.

14.h Hence, the above is illegal. Furthermore, the compiler is forbidden from choosing different Sizes by default, for the same reason.

14.i/5 {*AI12-0059-1*} The same issues apply to Alignment. Similar issues apply to Object_Size, Static_Predicate, and Dynamic_Predicate, but the chosen solution is different: explicit rules in 4.9.1 that ensure that the aspects are the same if specified.

{*AI12-0059-1*} The above static matching rule combined with the definition of static matching in 4.9.1 (after updating to add Object_Size) does not cause incompatibilities in existing Ada 2012 code that does not mention Object_Size. But it does constrain the implementation-defined value of Object_Size when it is not specified for a subtype; the above rule applies even in that case. (The effects noted in the example above would occur otherwise.) 14.j/5

{*AI12-0059-1*} We need this rule even though static matching explicitly excludes confirming values of Object_Size. That's because a general access type can designate any aliased object whose subtype statically matches the designated subtype. Since the Object_Size of a subtype determines the number of bits allocated for an aliased object of the subtype, if we allowed different Object_Sizes for statically matching subtypes, we'd be allowing the access type to designate objects with differing numbers of bits. That isn't going to work. 14.k/5

{*8652/0040*} {*AI95-00108-01*} {*AI05-0009-1*} {*AI05-0295-1*} A derived type inherits each type-related representation aspect of its parent type that was directly specified before the declaration of the derived type, or (in the case where the parent is derived) that was inherited by the parent type from the grandparent type. A derived subtype inherits each subtype-specific representation aspect of its parent subtype that was directly specified before the declaration of the derived type, or (in the case where the parent is derived) that was inherited by the parent subtype from the grandparent subtype, but only if the parent subtype statically matches the first subtype of the parent type. An inherited representation aspect is overridden by a subsequent aspect_specification or representation item that specifies a different value for the same aspect of the type or subtype. 15/3

To be honest: A record_representation_clause for a record extension does not override the layout of the parent part; if the layout was specified for the parent type, it is inherited by the record extension. 15.a

Ramification: If a representation item for the parent appears after the derived_type_definition, then inheritance does not happen for that representation item. 15.b

{*AI05-0009-1*} {*AI05-0295-1*} If an inherited aspect is confirmed by an aspect_specification or a later representation item for a derived type, the confirming specification does not override the inherited one. Thus the derived type has both a specified confirming value and an inherited nonconfirming representation value — this means that rules that apply only to nonconfirming representation values still apply to this type. 15.b.1/3

{*AI12-0109-1*} If an aspect was specified by an aspect_specification and the parent type has not yet been frozen, then the inherited aspect might not yet have been resolved and evaluated. The implementation will need to have a mechanism to handle such an aspect. 15.b.2/4

{*8652/0040*} {*AI95-00108-01*} {*AI95-00444-01*} {*AI05-0183-1*} {*AI05-0295-1*} {*AI12-0396-1*} In contrast, whether type-related operational aspects are inherited by a derived type depends on each specific aspect; unless specified, an operational aspect is not inherited. When type-related operational aspects are inherited by a derived type, aspects that were directly specified by aspect_specifications or operational items that are visible at any point within the immediate scope of the derived type declaration, or (in the case where the parent is derived) that were inherited by the parent type from the grandparent type, are inherited. An inherited operational aspect is overridden by an aspect_specification or operational item that specifies the same aspect of the type. 15.1/5

Ramification: As with representation items, if an operational item for the parent appears after the derived_type_-definition, then inheritance does not happen for that operational item. 15.b.3/1

{*AI12-0396-1*} Unlike representation aspects, operational aspects can be inherited at any point in the immediate scope, and can be overridden by aspect_specifications or operational items that occur at a point before or after the inheritance takes place. 15.b.4/5

{*AI12-0396-1*} When a type-related operational aspect is inherited, the rules for inheritance depend on the nature of the aspect (see 13.1.1). Unless otherwise specified for a given aspect, these rules are as follows: 15.2/5

- For an operational aspect that is a value, the inherited aspect has the same value; 15.3/5
- For an operational aspect that is a name: 15.4/5
  - if the name denotes one or more primitive subprograms of the type, the inherited aspect is a name that denotes the corresponding primitive subprogram(s) of the derived type; 15.5/5

Discussion: {*AI12-0005-1*} A primitive subprogram that is declared after the end of the enclosing declaration list of a derived type (in particular, in the private part of a package if the derived type is declared in the package's visible part) 15.b.6/5

is not the “corresponding primitive subprogram” in the sense of this rule. In a case like this, the corresponding primitive subprogram is actually the inherited subprogram. This doesn't make a difference for tagged types, because of the “dispatching” semantics used, which means a call on the inherited subprogram actually “reaches” the body of the overriding. But for untagged types, overriding an inherited subprogram of an untagged derived type in the private part is “too late” to have an effect on external uses of the primitive, since non-visible overridings are not generally reachable, and a call that only “sees” the inherited subprogram goes to the body of the parent's operation, effectively ignoring the private overriding. This same rule applies to aspects that denote an inherited subprogram of an untagged derived type — the private overriding is effectively ignored.

15.6/5 • otherwise, the inherited aspect is a name that denotes the same entity or entities as the original aspect;

15.7/5 • {*AI12-0396-1*} {*AI12-0423-1*} For an operational aspect that is an identifier specific to the aspect, the inherited aspect is the same identifier;

15.8/5 • {*AI12-0396-1*} {*AI12-0423-1*} For an operational aspect that is an expression or an aggregate, the inherited aspect is a corresponding expression or aggregate where each name, value, and identifier follows these same rules for inheritance.

16 Each aspect of representation of an entity is as follows:

17 • If the aspect is *specified* for the entity, meaning that it is either directly specified or inherited, then that aspect of the entity is as specified, except in the case of Storage_Size, which specifies a minimum.

17.a **Ramification:** This rule implies that queries of the aspect return the specified value. For example, if the user writes “**for** X'Size **use** 32;”, then a query of X'Size will return 32.

18 • If an aspect of representation of an entity is not specified, it is chosen by default in an unspecified manner.

18.a/3 **Ramification:** {*8652/0009*} {*AI95-00137-01*} {*AI05-0295-1*} Note that specifying a representation aspect can affect the semantics of the entity.

18.b The rules forbid things like “**for** S'Base'Alignment **use** ...” and “**for** S'Base **use** record ...”.

18.c **Discussion:** The intent is that implementations will represent the components of a composite value in the same way for all subtypes of a given composite type. Hence, Component_Size and record layout are type-related aspects.

18.d/3 **Ramification:** {*AI05-0083-1*} As noted previously, in the case of an object, the entity mentioned in this text is a specific view of an object. That means that only references to the same view of an object that has a specified value for a representation aspect *R* necessarily have that value for the aspect *R*. The value of the aspect *R* for a different view of that object is unspecified. In particular, this means that the representation values for by-reference parameters is unspecified; they do not have to be the same as those of the underlying object.

18.1/5 {*8652/0040*} {*AI95-00108-01*} {*AI12-0396-1*} If an operational aspect is *specified* for an entity (meaning that it is either directly specified or, if type-related or subtype-specific, inherited), then that aspect of the entity is as specified. Otherwise, the aspect of the entity has the default value for that aspect.[For aspects that are neither type-related nor subtype-specific, the terms “specified” and “directly specified” are equivalent.]

18.e/5 **Proof:** {*AI12-0396-1*} Aspect inheritance is only defined for types and subtypes.

18.2/5 {*AI95-00291-02*} {*AI05-0295-1*} {*AI12-0396-1*} An aspect_specification or representation item that specifies a representation aspect that would have been chosen in the absence of the aspect_specification or representation item is said to be *confirming*. The aspect value specified in this case is said to be a *confirming* representation aspect value. Other values of the aspect are said to be *nonconfirming*, as are the aspect_specifications and representation items that specified them. Similarly, an aspect_specification or operational item that specifies an operational aspect to be the same as the definition it would have by default is said to be *confirming*; otherwise it is *nonconfirming*.

18.f/5 **Discussion:** {*AI12-0005-1*} As noted at the beginning of this subclause, we have a Language Design Principle that confirming aspects do not change the semantics. However, it is not a Language Design Principle principle that one can always specify a confirming aspect. Some aspects can never be confirmed. For instance, the default implementation of a stream-oriented attribute cannot be confirmed, as any subprogram that can be specified is not the same as the default

subprogram, and thus is nonconfirming. Whether the effect is the same is not relevant for this purpose; it would be very difficult to formally define what it means to have the same effect. (Note that one can name any implementation for a stream-oriented attribute by using the associated attribute but specifying that by name would violate the circular aspect definition rule.) This is true for any implicitly composed aspect. Similarly, aspect Default_Value cannot be confirmed as the default is that there is no default value; any value that can be specified is not that.

Dynamic Semantics

{*8652/0009*} {*AI95-00137-01*} For the elaboration of an aspect_clause, any evaluable constructs within it are evaluated. 19/1

Ramification: {*AI05-0299-1*} Elaboration of representation pragmas is covered by the general rules for pragmas in 2.8. 19.a/3

Implementation Permissions

{*AI05-0295-1*} An implementation may interpret representation aspects in an implementation-defined manner. An implementation may place implementation-defined restrictions on the specification of representation aspects. A *recommended level of support* is defined for the specification of representation aspects and related features in each subclause. These recommendations are changed to requirements for implementations that support the Systems Programming Annex (see C.2, "Required Representation Support"). 20/3

Implementation defined: The interpretation of each representation aspect. 20.a/3

Implementation defined: Any restrictions placed upon the specification of representation aspects. 20.b/3

Ramification: Implementation-defined restrictions may be enforced either at compile time or at run time. There is no requirement that an implementation justify any such restrictions. They can be based on avoiding implementation complexity, or on avoiding excessive inefficiency, for example. 20.c

{*8652/0009*} {*AI95-00137-01*} There is no such permission for operational aspects. 20.c.1/1

Implementation Advice

{*AI05-0295-1*} The recommended level of support for the specification of all representation aspects is qualified as follows: 21/3

- {*AI95-00291-02*} {*AI05-0295-1*} A confirming specification for a representation aspect should be supported. 21.1/3

  To be honest: {*AI05-0295-1*} A confirming representation aspect value might not be possible for some entities. For instance, consider an unconstrained array. The size of such a type is implementation-defined, and might not actually be a representable value, or might not be static. 21.a/3

- {*AI05-0295-1*} {*AI12-0444-1*} An implementation is not required to support the specification for a representation aspect that contains nonstatic expressions, unless each nonstatic expression is a name that statically denotes a constant declared before the entity. 22/5

  Reason: This is to avoid the following sort of thing: 22.a

  ```
  {AI12-0005-1} X : Integer := F(...)                                    22.b/5
     with Address => Y;
  Y : Address := G(...);
  ```

  In the above, we have to evaluate the initialization expression for X before we know where to put the result. This seems like an unreasonable implementation burden. 22.c

  The above code should instead be written like this: 22.d

  ```
  {AI12-0005-1} Y : constant Address := G(...);                          22.e/5
  X : Integer := F(...)
     with Address => Y;
  ```

  This allows the expression "Y" to be safely evaluated before X is created. 22.f

  The constant could be a formal parameter of mode **in**. 22.g

  An implementation can support other nonstatic expressions if it wants to. Expressions of type Address are hardly ever static, but their value might be known at compile time anyway in many cases. 22.h

23/5 • {*AI12-0059-1*} {*AI12-0444-1*} An implementation is not required to support a specification for the Object_Size or Size for a given composite subtype, nor the size or storage place for an object (including a component) of a given composite subtype, unless the constraints on the subtype and its composite subcomponents (if any) are all static constraints.

23.a/5 **Reason:** {*AI12-0059-1*} We don't want to require that Object_Size or Size be supported on types that might have a representation not completely specified at compile time, or are represented discontiguously, or are represented differently for different constraints.

24/5 • {*AI95-00291-02*} {*AI05-0295-1*} {*AI12-0444-1*} An implementation is not required to support specifying a nonconfirming representation aspect value if it can cause an aliased object or an object of a by-reference type to be allocated at a nonaddressable location or, when the alignment attribute of the subtype of such an object is nonzero, at an address that is not an integral multiple of that alignment.

24.a/1 **Reason:** The intent is that access types, type System.Address, and the pointer used for a by-reference parameter should be implementable as a single machine address — bit-field pointers should not be required. (There is no requirement that this implementation be used — we just want to make sure it's feasible.)

24.b/2 **Implementation Note:** {*AI95-00291-02*} We want subprograms to be able to assume the properties of the types of their parameters inside of subprograms. While many objects can be copied to allow this (and thus do not need limitations), aliased or by-reference objects cannot be copied (their memory location is part of their identity). Thus, the above rule does not apply to types that merely allow by-reference parameter passing; for such types, a copy typically needs to be made at the call site when a bit-aligned component is passed as a parameter.

25/5 • {*AI95-00291-02*} {*AI05-0295-1*} {*AI12-0444-1*} An implementation is not required to support specifying a nonconfirming representation aspect value if it can cause an aliased object of an elementary type to have a size other than that which would have been chosen by default.

25.a/2 **Reason:** Since all bits of elementary objects participate in operations, aliased objects must not have a different size than that assumed by users of the access type.

26/5 • {*AI95-00291-02*} {*AI05-0295-1*} {*AI12-0444-1*} An implementation is not required to support specifying a nonconfirming representation aspect value if it can cause an aliased object of a composite type, or an object whose type is by-reference, to have a size smaller than that which would have been chosen by default.

26.a/2 **Reason:** Unlike elementary objects, there is no requirement that all bits of a composite object participate in operations. Thus, as long as the object is the same or larger in size than that expected by the access type, all is well.

26.b/2 **Ramification:** This rule presumes that the implementation allocates an object of a size specified to be larger than the default size in such a way that access of the default size suffices to correctly read and write the value of the object.

27/5 • {*AI95-00291-02*} {*AI05-0295-1*} {*AI12-0444-1*} An implementation is not required to support specifying a nonconfirming subtype-specific representation aspect value for an indefinite or abstract subtype.

27.a/3 **Reason:** {*AI05-0295-1*} Representation aspects are often not well-defined for such types.

27.b/3 **Ramification:** {*AI95-00291-02*} {*AI05-0229-1*} A type with the Pack aspect specified will typically not be packed so tightly as to disobey the above rules. A Component_Size clause or record_representation_clause will typically be illegal if it disobeys the above rules. Atomic components have similar restrictions (see C.6, “Shared Variable Control”).

28/5 {*AI95-00291-02*} {*AI05-0295-1*} {*AI12-0444-1*} For purposes of these rules, the determination of whether specifying a representation aspect value for a type *can cause* an object to have some property is based solely on the properties of the type itself, not on any available information about how the type is used. In particular, it presumes that minimally aligned objects of this type can be declared at some point.

28.a/2 **Implementation Advice:** The recommended level of support for all representation items should be followed.

29/3 NOTE {*AI05-0229-1*} Aspects that can be specified are defined throughout this document, and are summarized in K.1.

Incompatibilities With Ada 83

29.a It is now illegal for a representation item to cause a derived by-reference type to have a different record layout from its parent. This is necessary for by-reference parameter passing to be feasible. This only affects programs that specify the

representation of types derived from types containing tasks; most by-reference types are new to Ada 95. For example, if A1 is an array of tasks, and A2 is derived from A1, it is illegal to apply a pragma Pack to A2.

Extensions to Ada 83

{*8652/0009*} {*AI95-00137-01*} Ada 95 allows additional aspect_clauses for objects. 29.b/1

Wording Changes from Ada 83

{*8652/0009*} {*AI95-00137-01*} The syntax rule for type_representation_clause is removed; the right-hand side of that rule is moved up to where it was used, in aspect_clause. There are two references to "type representation clause" in RM83, both in Section 13; these have been reworded. Also, the representation_clause has been renamed the aspect_clause to reflect that it can be used to control more than just representation aspects. 29.c/1

{*8652/0009*} {*AI95-00137-01*} {*AI95-00114-01*} We have defined a new term "representation item", which includes all representation clauses and representation pragmas, as well as component_clauses. This is convenient because the rules are almost identical for all of them. We have also defined the new terms "operational item" and "operational aspects" in order to conveniently handle new types of specifiable entities. 29.d/2

All of the forcing occurrence stuff has been moved into its own subclause (see 13.14), and rewritten to use the term "freezing". 29.e

RM83-13.1(10) requires implementation-defined restrictions on representation items to be enforced at compile time. However, that is impossible in some cases. If the user specifies a junk (nonstatic) address in an address clause, and the implementation chooses to detect the error (for example, using hardware memory management with protected pages), then it's clearly going to be a run-time error. It seems silly to call that "semantics" rather than "a restriction". 29.f

RM83-13.1(10) tries to pretend that representation_clauses don't affect the semantics of the program. One counter-example is the Small clause. Ada 95 has more counter-examples. We have noted the opposite above. 29.g

Some of the more stringent requirements are moved to C.2, "Required Representation Support". 29.h

Extensions to Ada 95

{*AI95-00291-02*} **Amendment Correction:** Confirming representation items are defined, and the recommended level of support is now that they always be supported. 29.i/2

Wording Changes from Ada 95

{*8652/0009*} {*AI95-00137-01*} **Corrigendum:** Added operational items in order to eliminate unnecessary restrictions and permissions on stream attributes. As part of this, representation_clause was renamed to aspect_clause. 29.j/2

{*8652/0009*} {*AI95-00137-01*} {*AI95-00326-01*} **Corrigendum:** Added wording to say that the partial and full views have the same operational and representation aspects. Ada 2005 extends this to cover all views, including the incomplete view. 29.k/2

{*8652/0040*} {*AI95-00108-01*} **Corrigendum:** Changed operational items to have inheritance specified for each such aspect. 29.l/2

{*AI95-00251-01*} Added wording to allow the rejection of types with progenitors that have conflicting representation items. 29.m/2

{*AI95-00291-02*} The description of the representation of an object was clarified (with great difficulty reaching agreement). Added wording to say that representation items on aliased and by-reference objects never need be supported if they would not be implementable without distributed overhead even if other recommended level of support says otherwise. This wording matches the rules with reality. 29.n/2

{*AI95-00444-01*} {*AI05-0005-1*} Added wording so that inheritance depends on whether operational items are visible rather than whether they occur before the declaration (we don't want to look into private parts). Also limited operational inheritance to untagged types to avoid anomalies with private extensions (this is not incompatible, no existing operational attribute used this capability). Also added wording to clearly define that subprogram inheritance works like derivation of subprograms. 29.o/3

Incompatibilities With Ada 2005

{*AI05-0106-1*} {*AI12-0064-2*} {*AI12-0396-1*} **Correction:** Specifying a language-defined aspect for a generic formal parameter is no longer allowed. Most aspects could not be specified on these anyway; moreover, this was not allowed in Ada 83, so it is unlikely that compilers are supporting this as a capability (and it is not likely that they have a consistent definition of what it means if it is allowed). Thus, we expect this to occur rarely in existing programs. Note: This correction is repealed in Ada 2022, as a number of aspects are allowed on formals in that later language version. 29.p/5

Wording Changes from Ada 2005

29.q/5 {*AI05-0009-1*} {*AI12-0005-1*} **Correction:** Defined that overriding of a representation aspect only happens for a nonconfirming representation item. This prevents a derived type from being considered to have only a confirming representation item when the value would be nonconfirming if given on a type that does not inherit any aspects of representation. This change just eliminates a wording confusion and ought not change any behavior.

29.r/3 {*AI05-0112-1*} **Correction:** Defined a default naming for representation aspects that are representation pragmas.

29.s/3 {*AI05-0183-1*} Added text ensuring that the rules for representational and operational items also apply appropriately to aspect_specifications; generalized operational aspects so that they can be defined for entities other than types. Any extensions are documented elsewhere.

29.t/3 {*AI05-0295-1*} Rewrote many rules to be in terms of "specifying a representation aspect" rather than use of a "representation item". This better separates *how* an aspect is specified from *what* rules apply to the value of the aspect.

Incompatibilities With Ada 2012

29.u/4 {*AI12-0109-1*} **Corrigendum:** Added a rule that makes it illegal to specify a representation value after a type is derived from an untagged by-reference type. This restriction is incompatible, but since the implementation would have had to copy an object that does not allow copying in order to change the representation for any implicit or explicit conversion between the original and the derived type, it is unlikely that any program could exist without running into internal compiler errors or bogus results.

29.v/5 {*AI12-0181-1*} **Correction:** Added a rule preventing self-referencing representation or operational aspects. This is technically incompatible, but since the similar representation or operational item has been illegal since they've existed, and they don't make any sense, it's unlikely that any implementation accepted them or that they appear in any program.

29.w/5 {*AI12-0222-1*} **Correction:** Added a rule preventing giving a representation aspect on a partial view. Since this has always been prohibited for other kinds of representation items, it's unlikely that any implementation accepted them or that they appear in any program.

Extensions to Ada 2012

29.x/5 {*AI12-0376-1*} It is now allowed to specify type-related representation aspects for an untagged derived type that has primitive operations, so long as the type is not a by-reference type.

Wording Changes from Ada 2012

29.y/5 {*AI12-0116-1*} {*AI12-0396-1*} **Corrigendum:** Clarified that an aspect (any aspect) can be specified only once for an entity, no matter what means of specifying it are used.

29.z/5 {*AI12-0059-1*} Added wording changes to support Object_Size.

29.aa/5 {*AI12-0396-1*} **Correction:** Clarified that many of these rules only make sense for type-related aspects.

29.bb/5 {*AI12-0396-1*} {*AI12-0419-1*} {*AI12-0423-1*} **Correction:** Clarified how inheritance works for operational aspects that are not values.

29.cc/5 {*AI12-0427-1*} Move the general requirements for aspects that are subprograms here from 13.3.

13.1.1 Aspect Specifications

1/3 {*AI05-0183-1*} [Certain representation or operational aspects of an entity may be specified as part of its declaration using an aspect_specification, rather than using a separate representation or operational item.] The declaration with the aspect_specification is termed the *associated declaration*.

Syntax

2/3 {*AI05-0183-1*} aspect_specification ::=
with aspect_mark [=> aspect_definition] {,
aspect_mark [=> aspect_definition] }

3/3 {*AI05-0183-1*} aspect_mark ::= *aspect*_identifier['Class]

4/5 {*AI05-0183-1*} {*AI12-0187-1*} {*AI12-0285-1*} {*AI12-0373-1*} aspect_definition ::=
name | expression | identifier
| aggregate | global_aspect_definition

Language Design Principles

{*AI05-0183-1*} {*AI05-0267-1*} The aspect_specification is an optional element in most kinds of declarations. Here is a list of all kinds of declarations and an indication of whether or not they allow aspect clauses, and in some cases a short discussion of why (* = allowed, NO = not allowed). Kinds of declarations with no indication are followed by their subdivisions (which have indications). 4.a/3

{*AI12-0005-1*} {*AI12-0061-1*} {*AI12-0079-3*} {*AI12-0395-1*} {*AI12-0398-1*} basic_declaration 4.b/5

type_declaration
full_type_declaration
*type declaration syntax**
task_type_declaration*

   -- There are no language-defined aspects that may be specified
   -- on return objects, but implementations might support some.
```

4.c/5 {*AI12-0005-1*} {*AI12-0169-1*}

```
 We also allow aspect_specifications on all kinds of bodies, but there are no language-defined aspects
-- that may be specified on a body. These are allowed for implementation-defined aspects.
-- See above for subprogram bodies and stubs (as these can be declarations).
package_body*
task_body*
protected_body*
entry_body*
package_body_stub*
task_body_stub*
protected_body_stub*
```

4.d/3 {*AI05-0267-1*} Syntactically, aspect_specifications generally are located at the end of declarations. When a declaration is all in one piece such as a null_procedure_declaration, object_declaration, or generic_instantiation the aspect_specification goes at the end of the declaration; it is then more visible and less likely to interfere with the layout of the rest of the structure. However, we make an exception for program units (other than subprogram specifications) and bodies, in which the aspect_specification goes before the **is**. In these cases, the entity could be large and could contain other declarations that also have aspect_specifications, so it is better to put the aspect_specification toward the top of the declaration. (Some aspects – such as Pure – also affect the legality of the contents of a unit, so it would be annoying to only see those after reading the entire unit.)

Name Resolution Rules

5/5 {*AI05-0183-1*} {*AI12-0212-1*} An aspect_mark identifies an aspect of the entity defined by the associated declaration (the *associated entity*); the aspect denotes an object, a value, an expression, an aggregate, a subprogram, or some other kind of entity. If the aspect_mark identifies:

6/3 • an aspect that denotes an object, the aspect_definition shall be a name. The expected type for the name is the type of the identified aspect of the associated entity;

7/3 • an aspect that is a value or an expression, the aspect_definition shall be an expression. The expected type for the expression is the type of the identified aspect of the associated entity;

7.1/5 • {*AI12-0212-1*} an aspect that is an aggregate, the aspect definition shall be an expression that is an aggregate, with the form of the aggregate determined by the identified aspect;

7.a/5 **Ramification:** {*AI12-0212-1*} The only requirement here is that the expression is syntactically an aggregate; there is no requirement that it resolve to some particular type or even that it should resolve like an aggregate. Each aspect that uses an aggregate is responsible for specifying how the choice(s), component(s), and other contents of the aggregate are resolved and interpreted.

8/3 • an aspect that denotes a subprogram, the aspect_definition shall be a name; the expected profile for the name is the profile required for the aspect of the associated entity;

9/3 • an aspect that denotes some other kind of entity, the aspect_definition shall be a name, and the name shall resolve to denote an entity of the appropriate kind;

10/3 • an aspect that is given by an identifier specific to the aspect, the aspect_definition shall be an identifier, and the identifier shall be one of the identifiers specific to the identified aspect.

11/5 {*AI05-0183-1*} {*AI12-0373-1*} {*AI12-0427-1*} The usage names in an aspect_definition associated with a declaration [are not resolved at the point of the associated declaration, but rather] are resolved at the end of the immediately enclosing declaration list, or in the case of the declaration of a library unit, at the end of the visible part of the entity.

11.a **Ramification:** If an aspect_specification is not associated with a declaration (instead being part of a statement or expression), then it is resolved when the associated construct is resolved.

{*AI05-0183-1*} {*AI12-0180-1*} {*AI12-0220-1*} If the associated declaration is for a subprogram, entry, or access-to-subprogram type, the names of the formal parameters are directly visible within the aspect_definition, as are certain attributes, as specified elsewhere in this document for the identified aspect. If the associated declaration is a type_declaration, within the aspect_definition the names of any visible components, protected subprograms, and entries are directly visible, and the name of the first subtype denotes the current instance of the type (see 8.6). If the associated declaration is a subtype_declaration, within the aspect_definition the name of the new subtype denotes the current instance of the subtype. 12/5

Legality Rules

{*AI05-0183-1*} If the first freezing point of the associated entity comes before the end of the immediately enclosing declaration list, then each usage name in the aspect_definition shall resolve to the same entity at the first freezing point as it does at the end of the immediately enclosing declaration list. 13/3

{*AI12-0181-1*} {*AI12-0396-1*} An expression or name that causes freezing of an entity shall not occur within an aspect_specification that specifies a representation or operational aspect of that entity. 13.1/5

Reason: {*AI12-0181-1*} {*AI12-0396-1*} The rule prevents an aspect of an entity from depending (directly or indirectly) on properties of the entity itself. 13.a/5

Implementation Note: {*AI12-0396-1*} This check needs to be deferred at least to the freezing of the entity (as the aspect_definition is not resolved until then), and might be accomplished during the freezing of the aspect_definition (since it is closely related). Keep in mind that multiple other entities could be involved. 13.b/5

{*AI05-0183-1*} At most one occurrence of each aspect_mark is allowed within a single aspect_specification. The aspect identified by the aspect_mark shall be an aspect that can be specified for the associated entity (or view of the entity defined by the associated declaration). 14/3

Ramification: {*AI12-0116-1*} {*AI12-0005-1*} {*AI12-0396-1*} This rule prevents multiple specifications in the same aspect_specification. Rules in 13.1 prevent multiple specifications in different aspect_specifications (on different views of the same type, for instance), or between operational or representation items and an aspect_specification. 14.a/5

{*AI05-0183-1*} The aspect_definition associated with a given aspect_mark may be omitted only when the aspect_mark identifies an aspect of a boolean type, in which case it is equivalent to the aspect_definition being specified as True. 15/3

{*AI05-0183-1*} If the aspect_mark includes 'Class, then the associated entity shall be a tagged type or a primitive subprogram of a tagged type. 16/3

{*AI05-0183-1*} {*AI05-0267-1*} {*AI12-0064-2*} {*AI12-0194-1*} {*AI12-0380-1*} {*AI12-0407-1*} Unless otherwise specified for a specific aspect, a language-defined aspect cannot be specified on a renaming_declaration or a generic_formal_parameter_declaration. 17/5

Discussion: {*AI12-0064-2*} Implementation-defined aspects can be allowed on these, of course; the implementation will need to define the semantics. In addition, the language does not define default aspect matching rules for generic formals; only the handful of aspects allowed on formals have such rules. Therefore, the implementation will need to define actual type matching rules for any aspects allowed on formal types. 17.a/5

{*AI05-0183-1*} {*AI05-0267-1*} {*AI12-0105-1*} {*AI12-0380-1*} Unless specified otherwise, a language-defined aspect shall not be specified in an aspect_specification given on a completion of a program unit. 18/5

Reason: Most language-defined aspects (for example, preconditions) are intended to be available to callers, and specifying them on a body that has a separate declaration hides them from callers. Specific language-defined aspects may allow this, but they have to do so explicitly (by defining an alternative Legality Rule), and provide any needed rules about visibility. Note that this rule does not apply to implementation-defined aspects, so implementers need to carefully define whether such aspects can be applied to bodies and stubs, and what happens if they are specified on both the declaration and body of a unit. 18.a/3

18.1/4 {*AI05-0183-1*} {*AI12-0138-1*} If an aspect of a derived type is inherited from an ancestor type and has the boolean value True, the inherited value shall not be overridden to have the value False for the derived type, unless otherwise specified in this document.

18.b/4 **Reason:** Most boolean-valued language-defined aspects are associated with a representation pragma. The existing rules for such pragmas assume that the aspect cannot be removed. For instance, if a type *T* is declared to be Atomic, then all descendants of *T* are also Atomic. This rule ensures that remains the case when using the aspect notation instead of pragmas.

18.b.1/5 **Discussion:** This definition leaves holes for Boolean aspects that can be specified on non-first subtypes. Such aspects (for instance, Nonblocking) must have their own rules (that is, "otherwise specify" rules) that define the effects of inheriting from subtypes (both first subtypes and nonfirst subtypes).

18.2/5 {*AI12-0396-1*} If a given aspect is type-related and inherited, then within an aspect_definition for the aspect, if a name resolves to denote multiple visible subprograms, all or none of the denoted subprograms shall be primitives of the associated type.

18.b.2/5 **Reason:** {*AI12-0396-1*} This is necessary because the inheritance rules for names denoting primitive subprograms are different from those for names denoting other entities — see 13.1.

18.3/5 {*AI12-0138-1*} {*AI12-0206-1*} {*AI12-0419-1*} Certain type-related aspects are defined to be *nonoverridable*; all such aspects are inherited by derived types according to the rules given in 13.1. Any legality rule associated with a nonoverridable aspect is re-checked for the derived type, if the derived type is not abstract. Certain type-related and subtype-specific aspects are defined to be *additive*; such aspects are not inherited, but they can *apply* to the types derived from, or the subtypes based on, the original type or subtype, as defined for each such aspect. Finally, certain type-related aspects are *implicitly composed*; such aspects are not inherited, but rather a default implementation for a derived type is provided, as defined for each such aspect, based on that of its parent type, presuming the aspect for the parent type is available where the derived type is declared, plus those of any new components added as part of a type extension.

18.4/5 {*AI12-0138-1*} {*AI12-0206-1*} {*AI12-0211-1*} {*AI12-0396-1*} If a nonoverridable aspect is directly specified for a type *T*, then any explicit specification of that aspect for any descendant of *T* (other than *T* itself) shall be *confirming*. In the case of an aspect that is a name, this means that the specified name shall *match* the inherited aspect in the sense that it shall denote the same declarations as would the inherited name. Similarly, for an aspect that is an expression or an aggregate, confirming means the defining expression is fully conformant (see 6.3.1) with the defining expression for the inherited aspect, with the added rule that an identifier that is specific to the aspect is the same as the corresponding identifier in the inherited aspect.

18.5/5 {*AI12-0138-1*} {*AI12-0396-1*} If a full type has a partial view, and a given nonoverridable aspect is allowed for both the full view and the partial view, then the given aspect for the partial view and the full view shall be the same: the aspect shall be directly specified only on the partial view; if the full type inherits the aspect, then a matching definition shall be specified (directly or by inheritance) for the partial view.

18.c/4 **Ramification:** In order to enforce these rules without breaking privacy, we cannot allow a private type that could have a particular overridable aspect to have a hidden definition of that aspect. There is no problem if the private type does not allow the aspect (as the aspect could not be specified on descendants in that case).

18.6/5 {*AI12-0211-1*} If a type inherits a nonoverridable aspect from multiple ancestors, the value of the aspect inherited from any given ancestor shall be confirming of the values inherited from all other ancestors.

18.d/5 **Reason:** {*AI12-0005-1*} {*AI12-0211-1*} If more than one progenitor of a type *T* specifies a nonoverridable aspect, they all have to specify the same or matching values for that aspect. Otherwise, we'd have two different values for the aspect that depend on which progenitor we inherit from.

18.7/5 {*AI12-0138-1*} {*AI12-0211-1*} In addition to the places where Legality Rules normally apply (see 12.3), these rules about nonoverridable aspects also apply in the private part of an instance of a generic unit.

Discussion: We don't need an assume-the-worst rule for most nonoverridable aspects as they only work on tagged types and deriving from formal tagged types is not allowed in generic bodies. In the case of Implicit_Dereference, a derivation in a generic body does not cause problems (the ancestor necessarily cannot have the aspect, else specifying the aspect would be illegal), as there could be no place with visibility on both aspects. In the case of Max_Entry_Queue_Length, it is only allowed on task and protected types, and on entries, and there are not formal versions of any of those things. In the case of No_Controlled_Parts, we defined an assume-the-worst rule with the aspect. 18.e/5

{*AI12-0437-1*} A list of all nonoverridable aspects can be found in the index, under “nonoverridable aspect”. 18.f/5

Static Semantics

{*AI05-0183-1*} Depending on which aspect is identified by the aspect_mark, an aspect_definition specifies: 19/3

- a name that denotes a subprogram, object, or other kind of entity; 20/3
- {*AI12-0427-1*} an expression (other than an aggregate), which is either evaluated to produce a single value, or which (as in a precondition) is to be evaluated at particular points during later execution; 21/5
- {*AI12-0427-1*} an identifier specific to the aspect; or 22/5
- {*AI12-0427-1*} an aggregate, which is positional or named, and is composed of elements of any of these four kinds of constructs. 22.1/5

{*AI05-0183-1*} The identified aspect of the associated entity, or in some cases, the view of the entity defined by the declaration, is as specified by the aspect_definition (or by the default of True when boolean). Whether an aspect_specification *applies* to an entity or only to the particular view of the entity defined by the declaration is determined by the aspect_mark and the kind of entity. The following aspects are view specific: 23/3

- An aspect specified on an object_declaration; 24/3
- An aspect specified on a subprogram_declaration; 25/3
- An aspect specified on a renaming_declaration. 26/3

{*AI05-0183-1*} All other aspect_specifications are associated with the entity, and *apply* to all views of the entity, unless otherwise specified in this document. 27/3

{*AI05-0183-1*} {*AI12-0106-1*} If the aspect_mark includes 'Class (a *class-wide aspect*), then, unless specified otherwise for a particular class-wide aspect: 28/4

- if the associated entity is a tagged type, the specification *applies* to all descendants of the type; 29/3
- if the associated entity is a primitive subprogram of a tagged type *T*, the specification *applies* to the corresponding primitive subprogram of all descendants of *T*. 30/3

{*AI05-0183-1*} {*AI05-0229-1*} All specifiable operational and representation attributes may be specified with an aspect_specification instead of an attribute_definition_clause (see 13.3). 31/3

Ramification: The name of the aspect is the same as that of the attribute (see 13.3), so the aspect_mark is the attribute_designator of the attribute. 31.a/3

{*AI12-0005-1*} Unless specified otherwise, all of the requirements for specifying a particular aspect with an attribute_definition_clause also apply to an aspect_specification for the aspect. These are enforced at the freezing point of the entity. For example, when specifying the Size aspect of a subtype, the expression has to be a static expression with an integer type and a nonnegative value, all of the recommended level of support requirements apply if Annex C is supported (see C.2), and so on. 31.b/5

{*AI05-0229-1*} {*AI12-0154-1*} {*AI12-0417-1*} Some aspects are defined to be *library unit aspects*. Library unit aspects are of type Boolean. The expression specifying a library unit aspect shall be static. Library unit aspects are defined for all program units, but shall be specified only for library units. Notwithstanding what this document says elsewhere, the expression of a library unit aspect is resolved 32/5

and evaluated at the point where it occurs in the aspect_specification[, rather than the first freezing point of the associated unit].

32.a/3 **Ramification:** The name of the aspect is the same as that of the pragma (see 13.1), so the aspect_mark is the name of the pragma.

33/3 {*AI05-0229-1*} In addition, other operational and representation aspects not associated with specifiable attributes or representation pragmas may be specified, as specified elsewhere in this document.

34/4 *This paragraph was deleted.*{*AI05-0183-1*} {*AI12-0138-1*}

35/3 {*AI05-0183-1*} If a Legality Rule or Static Semantics rule only applies when a particular aspect has been specified, the aspect is considered to have been specified only when the aspect_specification or attribute_definition_clause is visible (see 8.3) at the point of the application of the rule.

35.a/3 **Reason:** Some rules only apply when an aspect has been specified (for instance, an indexable type is one that has aspect Variable_Indexing specified). In order to prevent privacy breaking, this can only be true when the specification of the aspect is visible. In particular, if the Variable_Indexing aspect is specified on the full view of a private type, the private type is not considered an indexable type.

36/3 {*AI05-0183-1*} Alternative legality and semantics rules may apply for particular aspects, as specified elsewhere in this document.

Dynamic Semantics

37/5 {*AI05-0183-1*} {*AI12-0355-2*} At the freezing point of the associated entity, the aspect_specification is elaborated. When appearing in a construct other than a declaration, an aspect_specification is elaborated as part of the execution of the construct. The elaboration of the aspect_specification consists of the elaboration of each aspect_definition in an arbitrary order. The elaboration of an aspect_definition includes the evaluation of any name or expression that is part of the aspect_definition unless the part is itself an expression. If the corresponding aspect (or part thereof) represents an expression (as in a precondition), the elaboration of that part has no effect; the expression is evaluated later at points within the execution as specified elsewhere in this document for the particular aspect.

Implementation Permissions

38/3 {*AI05-0183-1*} Implementations may support implementation-defined aspects. The aspect_specification for an implementation-defined aspect may use an implementation-defined syntax for the aspect_definition, and may follow implementation-defined legality and semantics rules.

38.a/5 **Discussion:** {*AI12-0389-1*} The intent is to allow implementations to support aspects that are defined, for example, by a subtype_indication rather than an expression or a name. We chose not to try to enumerate all possible aspect_definition syntaxes, but to give implementations maximum freedom.

38.a.1/3 **Implementation defined:** Implementation-defined aspects, including the syntax for specifying such aspects and the legality rules for such aspects.

39/5 {*AI12-0389-1*} An implementation may ignore the specification of an unrecognized aspect; if an implementation chooses to ignore such an aspect specification (as opposed to rejecting it), then it has no effect on the semantics of the program except for possibly (and this is not required) the rejection of syntax errors within the aspect_definition.

39.a/5 **Discussion:** {*AI12-0389-1*} Identifying the textual end of an aspect_definition for an unrecognized aspect may be challenging, particularly if the syntax for the unrecognized aspect's aspect_definition is implementation-defined. It is not specified how an implementation might accomplish this. Note that an implementation is never *required* to be able to do this; if an aspect_definition for an unrecognized aspect is problematic in any way, then it can always be rejected (as opposed to being ignored).

Extensions to Ada 2005

39.b/3 {*AI05-0183-1*} {*AI05-0229-1*} {*AI05-0267-1*} Aspect specifications are new.

Inconsistencies With Ada 2012

{*AI12-0180-1*} **Correction:** Names of protected subprograms and entries are now directly visible in an aspect of a type declaration. This was always intended to be the case, but it was omitted from the Reference Manual by an editing error. In the unlikely case that a parameterless protected function has the same name and type as an entity used in a type invariant expression, the meaning would change from the outside entity which would now be hidden by the protected function. It is much more likely that a conflict (itself rather unlikely) would cause a resolution failure. 39.c/5

Incompatibilities With Ada 2012

{*AI12-0154-1*} **Corrigendum:** Added a clarification that aspects that correspond to library unit pragmas are resolved and evaluated immediately. This is incompatible, as a reference to an entity defined after the aspect will now be illegal. However, this would have required retroactive enforcement of such aspects, which is a new capability not available from the associated pragma, and moreover no known Ada 2012 implementation has ever allowed late evaluation of such aspects. As such, there should be no practical incompatibility. 39.d/4

{*AI12-0005-1*} {*AI12-0220-1*} Parameters of access-to-subprogram types are now visible in aspect specifications. This can be incompatible if some entity with the same name as a parameter is used in an existing aspect specification. We believe that all such aspects require either static expressions or a subprogram that is statically denoted; since a parameter can be neither of these and hides everything else, all such cases will be caught at compile-time. In addition, we expect such cases to be very rare. 39.e/5

Extensions to Ada 2012

{*AI12-0212-1*} An aspect can be an unresolved aggregate, these can be used to specify a list of entities, or to set a group of different but related properties with a single aspect. 39.f/5

{*AI12-0355-2*} Aspect specifications can appear in, and apply to, constructs other than declarations. 39.g/5

{*AI12-0389-1*} An unrecognized aspect specification can be ignored. 39.h/5

Wording Changes from Ada 2012

{*AI12-0105-1*} **Corrigendum:** Clarified the wording so that the restriction against language-defined aspects on subprogram completions includes completions that are expressions functions and null procedures. 39.i/4

{*AI12-0106-1*} **Corrigendum:** Defined class-wide aspect for use in rules in 13.13.2. 39.j/4

{*AI12-0138-1*} **Corrigendum:** Added a definition of nonoverridable aspects. This is necessary to prevent generic contract problems with formal derived types. 39.k/4

{*AI12-0194-1*} **Correction:** Added entry_body to the list of entities that don't allow any language-defined aspects. This was an oversight in AI12-0169-1 which allowed aspect_specifications on an entry_body in the first place. 39.l/5

{*AI12-0206-1*} **Correction:** Extended the definition of nonoverridable aspects to cover most kinds of aspects. 39.m/5

{*AI12-0211-1*} **Correction:** Added a rule so that the a nonoverridable aspect has to be the same for every ancestor of a type. 39.n/5

{*AI12-0355-2*} {*AI12-0427-1*} Clarified when elaboration and resolution of aspect_specifications not associated with a declaration occur. 39.o/5

{*AI12-0380-1*} {*AI12-0407-1*} Revised the rules about entities that cannot have specified language-defined aspects. The body portion of the rule was changed to a general prohibition on specifying language-defined aspects on completions (this allows specifying aspects on bodies that act as a declaration, and eliminates the list of entities, which was a maintenance nightmare). Then the remaining entities (renamings and generic formal parameters) were revised to allow specific aspects, since Nonblocking (see 9.5), as well as Pre and Post, are now allowed on generic formal parameters. 39.p/5

{*AI12-0373-1*} Added the missing definition for resolution of entities found in aspects of library units. 39.q/5

{*AI12-0396-1*} **Correction:** Defined confirming for nonoverridable aspects that are expressions or aggregates. 39.r/5

{*AI12-0419-1*} Added a description of additive and implicitly composed aspects in order to explain the different inheritance mechanisms used by existing aspects. 39.s/5

13.2 Packed Types

{*AI05-0229-1*} [The Pack aspect having the value True specifies that storage minimization should be the main criterion when selecting the representation of a composite type.] 1/3

Paragraphs 2 through 4 were moved to Annex J, "Obsolescent Features".

Language Design Principles

1.a/4 {*AI12-0001-1*} If the default representation already uses minimal storage for a particular type, aspect Pack might not cause any representation change. It follows that aspect Pack should always be allowed, even when it has no effect on representation.

1.b/4 As a consequence, the chosen representation for a packed type may change during program maintenance even if the type is unchanged (in particular, if other representation aspects change on a part of the type). This is different than the behavior of most other representation aspects, whose properties remain guaranteed no matter what changes are made to other aspects.

1.c/4 Therefore, aspect Pack should not be used to achieve a representation required by external criteria. For instance, setting Component_Size to 1 should be preferred over using aspect Pack to ensure an array of bits. If future maintenance would make the array components aliased, independent, or atomic, the program would become illegal if Component_Size is used (immediately identifying a problem) while the aspect Pack version would simply change representations (probably causing a hard-to-find bug).

Static Semantics

5/3 {*AI05-0229-1*} For a full type declaration of a composite type, the following language-defined representation aspect may be specified:

5.1/3 Pack The type of aspect Pack is Boolean. When aspect Pack is True for a type, the type (or the extension part) is said to be *packed*. For a type extension, the parent part is packed as for the parent type, and specifying Pack causes packing only of the extension part.

5.a/3 **Aspect Description for Pack:** Minimize storage when laying out records and arrays.

5.2/3 If directly specified, the aspect_definition shall be a static expression. If not specified (including by inheritance), the aspect is False.

5.b/3 **Ramification:** {*AI05-0229-1*} The only high level semantic effect of specifying the Pack aspect is potential loss of independent addressability (see 9.10, “Shared Variables”).]

Implementation Advice

6 If a type is packed, then the implementation should try to minimize storage allocated to objects of the type, possibly at the expense of speed of accessing components, subject to reasonable complexity in addressing calculations.

6.a.1/2 **Implementation Advice:** Storage allocated to objects of a packed type should be minimized.

6.a/3 **Ramification:** {*AI05-0229-1*} Specifying the Pack aspect is for gaining space efficiency, possibly at the expense of time. If more explicit control over representation is desired, then a record_representation_clause, a Component_Size clause, or a Size clause should be used instead of, or in addition to, the Pack aspect.

6.1/4 *This paragraph was deleted.*{*AI95-00291-02*} {*AI12-0001-1*}

7/3 {*AI05-0229-1*} The recommended level of support for the Pack aspect is:

7.1/4 • {*AI12-0001-1*} Any component of a packed type that is of a by-reference type, that is specified as independently addressable, or that contains an aliased part, shall be aligned according to the alignment of its subtype.

7.a/4 **Ramification:** This also applies to atomic components. "Atomic" implies "specified as independently addressable", so we don't need to mention atomic here.

7.b/4 Other components do not have to respect the alignment of the subtype when packed; in many cases, the Recommended Level of Support will require the alignment to be ignored.

8/5 • {*AI12-0001-1*} {*AI12-0444-1*} For a packed record type, the components should be packed as tightly as possible subject to the above alignment requirements, the Sizes of the component subtypes, and any record_representation_clause that applies to the type; the implementation is allowed to reorder components or cross aligned word boundaries to improve the packing. A component whose Size is greater than the word size may be allocated an integral number of words.

Ramification: The implementation can always allocate an integral number of words for a component that will not fit in a word. The rule also allows small component sizes to be rounded up if such rounding does not waste space. For example, if Storage_Unit = 8, then a component of size 8 is probably more efficient than a component of size 7 plus a 1-bit gap (assuming the gap is needed anyway). 8.a

- {*AI05-0009-1*} {*AI12-0001-1*} For a packed array type, if the Size of the component subtype is less than or equal to the word size, Component_Size should be less than or equal to the Size of the component subtype, rounded up to the nearest factor of the word size, unless this would violate the above alignment requirements. 9/4

This paragraph was deleted.{*AI12-0001-1*} 9.a/4

Implementation Advice: The recommended level of support for the Pack aspect should be followed. 9.b/3

Wording Changes from Ada 95

{*AI95-00291-02*} {*AI05-0229-1*} Added clarification that the Pack aspect can ignore alignment requirements on types that don't have by-reference or aliased parts. This was always intended, but there was no wording to that effect. 9.c/3

Extensions to Ada 2005

{*AI05-0229-1*} Aspect Pack is new; pragma Pack is now obsolescent. 9.d/3

Wording Changes from Ada 2005

{*AI05-0009-1*} **Correction:** Fixed so that the presence or absence of a confirming Component_Size representation clause does not change the meaning of the Pack aspect. 9.e/3

Wording Changes from Ada 2012

{*AI12-0001-1*} **Corrigendum:** Fixed so that the Recommended Level of Support does not require packing of components for which such packing would violate other representation items or aspects. This is not incompatible, as either such Pack aspects were treated as illegal or the Recommended Level of Support was ignored as impractical, neither of which would change the behavior of any working programs. (Other behavior cannot be justifed from the Reference Manual.) 9.f/4

13.3 Operational and Representation Attributes

{*8652/0009*} {*AI95-00137-01*} [The values of certain implementation-dependent characteristics can be obtained by interrogating appropriate operational or representation attributes. Some of these attributes are specifiable via an attribute_definition_clause.] 1/1

Language Design Principles

In general, the meaning of a given attribute should not depend on whether the attribute was specified via an attribute_definition_clause, or chosen by default by the implementation. 1.a

Syntax

```
attribute_definition_clause ::=
    for local_name'attribute_designator use expression;
  | for local_name'attribute_designator use name;
```
2

Name Resolution Rules

For an attribute_definition_clause that specifies an attribute that denotes a value, the form with an expression shall be used. Otherwise, the form with a name shall be used. 3

For an attribute_definition_clause that specifies an attribute that denotes a value or an object, the expected type for the expression or name is that of the attribute. For an attribute_definition_clause that specifies an attribute that denotes a subprogram, the expected profile for the name is the profile required for the attribute. For an attribute_definition_clause that specifies an attribute that denotes some other kind of entity, the name shall resolve to denote an entity of the appropriate kind. 4

4.a **Ramification:** For example, the Size attribute is of type *universal_integer*. Therefore, the expected type for Y in "**for** X'Size **use** Y;" is *universal_integer*, which means that Y can be of any integer type.

4.b **Discussion:** For attributes that denote subprograms, the required profile is indicated separately for the individual attributes.

4.c **Ramification:** For an attribute_definition_clause with a name, the name need not statically denote the entity it denotes. For example, the following kinds of things are allowed:

4.d
```
for Some_Access_Type'Storage_Pool use Storage_Pool_Array(I);
for Some_Type'Read use Subprogram_Pointer.all;
```

Legality Rules

5/3 {*8652/0009*} {*AI95-00137-01*} {*AI05-0183-1*} An attribute_designator is allowed in an attribute_definition_clause only if this Reference Manual explicitly allows it, or for an implementation-defined attribute if the implementation allows it. Each specifiable attribute constitutes an operational aspect or aspect of representation; the name of the aspect is that of the attribute.

5.a **Discussion:** For each specifiable attribute, we generally say something like, "The ... attribute may be specified for ... via an attribute_definition_clause."

5.b The above wording allows for T'Class'Alignment, T'Class'Size, T'Class'Input, and T'Class'Output to be specifiable.

5.c A specifiable attribute is not necessarily specifiable for all entities for which it is defined. For example, one is allowed to ask T'Component_Size for an array subtype T, but "**for** T'Component_Size **use** ..." is only allowed if T is a first subtype, because Component_Size is a type-related aspect.

6/5 *This paragraph was deleted.*{*AI12-0427-1*}

6.a/5 *This paragraph was deleted.*

6.b/5 `This paragraph was deleted.`

6.c/5 *This paragraph was deleted.*

Static Semantics

7/2 {*AI95-00270-01*} A *Size clause* is an attribute_definition_clause whose attribute_designator is Size. Similar definitions apply to the other specifiable attributes.

7.a **To be honest:** An attribute_definition_clause is type-related or subtype-specific if the attribute_designator denotes a type-related or subtype-specific attribute, respectively.

8 A *storage element* is an addressable element of storage in the machine. A *word* is the largest amount of storage that can be conveniently and efficiently manipulated by the hardware, given the implementation's run-time model. A word consists of an integral number of storage elements.

8.a **Discussion:** A storage element is not intended to be a single bit, unless the machine can efficiently address individual bits.

8.b **Ramification:** For example, on a machine with 8-bit storage elements, if there exist 32-bit integer registers, with a full set of arithmetic and logical instructions to manipulate those registers, a word ought to be 4 storage elements — that is, 32 bits.

8.c **Discussion:** The "given the implementation's run-time model" part is intended to imply that, for example, on an 80386 running MS-DOS, the word might be 16 bits, even though the hardware can support 32 bits.

8.d A word is what ACID refers to as a "natural hardware boundary".

8.e Storage elements may, but need not be, independently addressable (see 9.10, "Shared Variables"). Words are expected to be independently addressable.

8.1/3 {*AI95-00133-01*} {*AI05-0092-1*} A *machine scalar* is an amount of storage that can be conveniently and efficiently loaded, stored, or operated upon by the hardware. Machine scalars consist of an integral number of storage elements. The set of machine scalars is implementation defined, but includes at least the storage element and the word. Machine scalars are used to interpret component_clauses when the nondefault bit ordering applies.

8.e.1/2 **Implementation defined:** The set of machine scalars.

Ramification: {*AI05-0092-1*} A single storage element is a machine scalar in all Ada implementations. Similarly, a word is a machine scalar in all implementations (although it might be the same as a storage element). An implementation may define other machine scalars that make sense on the target (a half-word, for instance). 8.f/3

{*8652/0009*} {*AI95-00137-01*} {*AI05-0191-1*} {*AI12-0059-1*} The following representation attributes are defined: Address, Alignment, Size, Object_Size, Storage_Size, Component_Size, Has_Same_Storage, and Overlaps_Storage. 9/5

For a prefix X that denotes an object, program unit, or label: 10/1

X'Address Denotes the address of the first of the storage elements allocated to X. For a program unit or label, this value refers to the machine code associated with the corresponding body or statement. The value of this attribute is of type System.Address. 11

Ramification: Here, the "first of the storage elements" is intended to mean the one with the lowest address; the endianness of the machine doesn't matter. 11.a

{*AI05-0095-1*} The prefix of X'Address shall not statically denote a subprogram that has convention Intrinsic. X'Address raises Program_Error if X denotes a subprogram that has convention Intrinsic. 11.1/3

Address may be specified for stand-alone objects and for program units via an attribute_definition_clause. 12

Ramification: Address is not allowed for enumeration literals, predefined operators, derived task types, or derived protected types, since they are not program units. 12.a

Address is not allowed for intrinsic subprograms, either. That can be checked statically unless the prefix is a generic formal subprogram and the attribute reference is in the body of a generic unit. We define that case to raise Program_Error, in order that the compiler does not have to build a wrapper for intrinsic subprograms. 12.b/3

The validity of a given address depends on the run-time model; thus, in order to use Address clauses correctly, one needs intimate knowledge of the run-time model. 12.c

{*AI05-0229-1*} If the Address of an object is specified, any explicit or implicit initialization takes place as usual, unless the Import aspect is also specified for the object (in which case any necessary initialization is presumably done in the foreign language). 12.d/3

Any compilation unit containing an attribute_reference of a given type depends semantically on the declaration of the package in which the type is declared, even if not mentioned in an applicable with_clause — see 10.1.1. In this case, it means that if a compilation unit contains X'Address, then it depends on the declaration of System. Otherwise, the fact that the value of Address is of a type in System wouldn't make sense; it would violate the "legality determinable via semantic dependences" Language Design Principle. 12.e

AI83-00305 — If X is a task type, then within the body of X, X denotes the current task object; thus, X'Address denotes the object's address. 12.f

Interrupt entries and their addresses are described in J.7.1, "Interrupt Entries". 12.g

If X is not allocated on a storage element boundary, X'Address points at the first of the storage elements that contains any part of X. This is important for the definition of the Position attribute to be sensible. 12.h

Aspect Description for Address: Machine address of an entity. 12.i/3

Erroneous Execution

{*AI05-0009-1*} If an Address is specified, it is the programmer's responsibility to ensure that the address is valid and appropriate for the entity and its use; otherwise, program execution is erroneous. 13/3

Discussion: "Appropriate for the entity and its use" covers cases such as misaligned addresses, read-only code addresses for variable data objects (and nonexecutable data addresses for code units), and addresses which would force objects that are supposed to be independently addressable to not be. Such addresses may be "valid" as they designate locations that are accessible to the program, but the program execution is still erroneous (meaning that implementations do not have to worry about these cases). 13.a

Implementation Advice

For an array X, X'Address should point at the first component of the array, and not at the array bounds. 14

14.a.1/2 **Implementation Advice:** For an array X, X'Address should point at the first component of the array rather than the array bounds.

14.a **Ramification:** On the other hand, we have no advice to offer about discriminants and tag fields; whether or not the address points at them is not specified by the language. If discriminants are stored separately, then the Position of a discriminant might be negative, or might raise an exception.

15 The recommended level of support for the Address attribute is:

16 • X'Address should produce a useful result if X is an object that is aliased or of a by-reference type, or is an entity whose Address has been specified.

16.a **Reason:** Aliased objects are the ones for which the Unchecked_Access attribute is allowed; hence, these have to be allocated on an addressable boundary anyway. Similar considerations apply to objects of a by-reference type.

16.b An implementation need not go to any trouble to make Address work in other cases. For example, if an object X is not aliased and not of a by-reference type, and the implementation chooses to store it in a register, X'Address might return System.Null_Address (assuming registers are not addressable). For a subprogram whose calling convention is Intrinsic, or for a package, the implementation need not generate an out-of-line piece of code for it.

17 • An implementation should support Address clauses for imported subprograms.

18/2 • *This paragraph was deleted.*{*AI95-00291-02*}

18.a/2 *This paragraph was deleted.*

19 • If the Address of an object is specified, or it is imported or exported, then the implementation should not perform optimizations based on assumptions of no aliases.

19.a/2 **Implementation Advice:** The recommended level of support for the Address attribute should be followed.

20 NOTE 1 The specification of a link name with the Link_Name aspect (see B.1) for a subprogram or object is an alternative to explicit specification of its link-time address, allowing a link-time directive to place the subprogram or object within memory.

21 NOTE 2 The rules for the Size attribute imply, for an aliased object X, that if X'Size = Storage_Unit, then X'Address points at a storage element containing all of the bits of X, and only the bits of X.

Wording Changes from Ada 83

21.a The intended meaning of the various attributes, and their attribute_definition_clauses, is more explicit.

21.b The address_clause has been renamed to at_clause and moved to Annex J, “Obsolescent Features”. One can use an Address clause (“for T'Address **use** ...;”) instead.

21.c The attributes defined in RM83-13.7.3 are moved to Annex G, A.5.3, and A.5.4.

Wording Changes from Ada 2005

21.c.1/3 {*AI05-0183-1*} Defined that the names of aspects are the same as the name of the attribute; that gives a name to use in aspect_specifications (see 13.1.1).

Language Design Principles

21.d By default, the Alignment of a subtype should reflect the “natural” alignment for objects of the subtype on the machine. The Alignment, whether specified or default, should be known at compile time, even though Addresses are generally not known at compile time. (The generated code should never need to check at run time the number of zero bits at the end of an address to determine an alignment).

21.e There are two symmetric purposes of Alignment clauses, depending on whether or not the implementation has control over object allocation. If the implementation allocates an object, the implementation should ensure that the Address and Alignment are consistent with each other. If something outside the implementation allocates an object, the implementation should be allowed to assume that the Address and Alignment are consistent, but should not assume stricter alignments than that.

Static Semantics

22/2 {*AI95-00291-02*} For a prefix X that denotes an object:

23/2 X'Alignment

{*AI95-00291-02*} The value of this attribute is of type *universal_integer*, and nonnegative; zero means that the object is not necessarily aligned on a storage element boundary. If

X'Alignment is not zero, then X is aligned on a storage unit boundary and X'Address is an integral multiple of X'Alignment (that is, the Address modulo the Alignment is zero).

This paragraph was deleted.{*AI95-00291-02*} 24/2

Ramification: The Alignment is passed by an allocator to the Allocate operation; the implementation has to choose a value such that if the address returned by Allocate is aligned as requested, the generated code can correctly access the object. 24.a

The above mention of "modulo" is referring to the "**mod**" operator declared in System.Storage_Elements; if X **mod** N = 0, then X is by definition aligned on an N-storage-element boundary. 24.b

{*AI95-00291-02*} Alignment may be specified for [stand-alone] objects via an attribute_definition_clause; the expression of such a clause shall be static, and its value nonnegative. 25/2

Aspect Description for Alignment (object): Alignment of an object. 25.a/3

This paragraph was deleted.{*AI95-00247-01*} 26/2

{*AI95-00291-02*} For every subtype S: 26.1/2

S'Alignment 26.2/2

{*AI95-00291-02*} The value of this attribute is of type *universal_integer*, and nonnegative.

{*AI95-00051-02*} {*AI95-00291-02*} For an object X of subtype S, if S'Alignment is not zero, then X'Alignment is a nonzero integral multiple of S'Alignment unless specified otherwise by a representation item. 26.3/2

{*AI95-00291-02*} Alignment may be specified for first subtypes via an attribute_definition_clause; the expression of such a clause shall be static, and its value nonnegative. 26.4/2

Aspect Description for Alignment (subtype): Alignment of a subtype. 26.a/3

Erroneous Execution

Program execution is erroneous if an Address clause is given that conflicts with the Alignment. 27

Ramification: The user has to either give an Alignment clause also, or else know what Alignment the implementation will choose by default. 27.a

{*AI95-00051-02*} {*AI95-00291-02*} For an object that is not allocated under control of the implementation, execution is erroneous if the object is not aligned according to its Alignment. 28/2

Implementation Advice

{*AI05-0116-1*} For any tagged specific subtype *S*, *S*'Class'Alignment should equal *S*'Alignment. 28.1/3

Reason: A tagged object should never be less aligned than the alignment of the type of its view, so for a class-wide type T'Class, the alignment should be no greater than that of any type covered by T'Class. If the implementation only supports alignments that are required by the recommended level of support (and this is most likely), then the alignment of any covered type has to be the same or greater than that of T — which leaves the only reasonable value of T'Class'Alignment being T'Alignment. Thus we recommend this, but don't require it so that in the unlikely case that the implementation does support smaller alignments for covered types, it can select a smaller value for T'Class'Alignment. 28.a/3

Implementation Advice: For any tagged specific subtype *S*, *S*'Class'Alignment should equal *S*'Alignment. 28.a.1/3

The recommended level of support for the Alignment attribute for subtypes is: 29

- {*AI95-00051-02*} An implementation should support an Alignment clause for a discrete type, fixed point type, record type, or array type, specifying an Alignment value that is zero or a power of two, subject to the following: 30/2
- {*AI95-00051-02*} {*AI12-0444-1*} An implementation is not required to support an Alignment clause for a signed integer type specifying an Alignment greater than the largest Alignment value that is ever chosen by default by the implementation for any signed integer type. A corresponding limitation may be imposed for modular integer types, fixed point types, enumeration types, record types, and array types. 31/5

32/5 • {*AI95-00051-02*} {*AI12-0444-1*} An implementation is not required to support a nonconfirming Alignment clause that can cause the creation of an object of an elementary type that cannot be easily loaded and stored by available machine instructions.

32.1/5 • {*AI95-00291-02*} {*AI12-0444-1*} An implementation is not required to support an Alignment specified for a derived tagged type that is not a multiple of the Alignment of the parent type. An implementation is not required to support a nonconfirming Alignment specified for a derived untagged by-reference type.

32.a/2 **Ramification:** {*AI95-00291-02*} There is no recommendation to support any nonconfirming Alignment clauses for types not mentioned above. Remember that 13.1 requires support for confirming Alignment clauses for all types.

32.b/3 **Implementation Note:** {*AI05-0116-1*} An implementation that tries to support other alignments for derived tagged types will need to allow inherited subprograms to be passed objects that are less aligned than expected by the parent subprogram and type. This is unlikely to work if alignment has any effect on code selection. Similar issues arise for untagged derived types whose parameters are passed by reference.

33 The recommended level of support for the Alignment attribute for objects is:

34/2 • *This paragraph was deleted.*{*AI95-00291-02*}

35 • For stand-alone library-level objects of statically constrained subtypes, the implementation should support all Alignments supported by the target linker. For example, page alignment is likely to be supported for such objects, but not for subtypes.

35.1/2 • {*AI95-00291-02*} For other objects, an implementation should at least support the alignments supported for their subtype, subject to the following:

35.2/5 • {*AI95-00291-02*} {*AI12-0444-1*} An implementation is not required to support Alignments specified for objects of a by-reference type or for objects of types containing aliased subcomponents if the specified Alignment is not a multiple of the Alignment of the subtype of the object.

35.a/2 **Implementation Advice:** The recommended level of support for the Alignment attribute should be followed.

36 NOTE 3 Alignment is a subtype-specific attribute.

37/2 *This paragraph was deleted.*{*AI95-00247-01*}

37.a/2 *This paragraph was deleted.*

38/3 NOTE 4 {*AI05-0229-1*} {*AI05-0269-1*} A component_clause, Component_Size clause, or specifying the Pack aspect as True can override a specified Alignment.

38.a **Discussion:** Most objects are allocated by the implementation; for these, the implementation obeys the Alignment. The implementation is of course allowed to make an object *more* aligned than its Alignment requires — an object whose Alignment is 4 might just happen to land at an address that's a multiple of 4096. For formal parameters, the implementation might want to force an Alignment stricter than the parameter's subtype. For example, on some systems, it is customary to always align parameters to 4 storage elements.

38.b Hence, one might initially assume that the implementation could evilly make all Alignments 1 by default, even though integers, say, are normally aligned on a 4-storage-element boundary. However, the implementation cannot get away with that — if the Alignment is 1, the generated code cannot assume an Alignment of 4, at least not for objects allocated outside the control of the implementation.

38.c Of course implementations can assume anything they can prove, but typically an implementation will be unable to prove much about the alignment of, say, an imported object. Furthermore, the information about where an address "came from" can be lost to the compiler due to separate compilation.

38.d/3 {*AI95-00114-01*} {*AI05-0229-1*} The Alignment of an object that is a component of a packed composite object will usually be 0, to indicate that the component is not necessarily aligned on a storage element boundary. For a subtype, an Alignment of 0 means that objects of the subtype are not normally aligned on a storage element boundary at all. For example, an implementation might choose to make Component_Size be 1 for an array of Booleans, even when the Pack aspect has not been specified for the array. In this case, Boolean'Alignment would be 0. (In the presence of tasking, this would in general be feasible only on a machine that had atomic test-bit and set-bit instructions.)

38.e If the machine has no particular natural alignments, then all subtype Alignments will probably be 1 by default.

38.f Specifying an Alignment of 0 in an attribute_definition_clause does not require the implementation to do anything (except return 0 when the Alignment is queried). However, it might be taken as advice on some implementations.

It is an error for an Address clause to disobey the object's Alignment. The error cannot be detected at compile time, in general, because the Address is not necessarily known at compile time (and is almost certainly not static). We do not require a runtime check, since efficiency seems paramount here, and Address clauses are treading on thin ice anyway. Hence, this misuse of Address clauses is just like any other misuse of Address clauses — it's erroneous. 38.g

A type extension can have a stricter Alignment than its parent. This can happen, for example, if the Alignment of the parent is 4, but the extension contains a component with Alignment 8. The Alignment of a class-wide type or object will have to be the maximum possible Alignment of any extension. 38.h

The recommended level of support for the Alignment attribute is intended to reflect a minimum useful set of capabilities. An implementation can assume that all Alignments are multiples of each other — 1, 2, 4, and 8 might be the only supported Alignments for subtypes. An Alignment of 3 or 6 is unlikely to be useful. For objects that can be allocated statically, we recommend that the implementation support larger alignments, such as 4096. We do not recommend such large alignments for subtypes, because the maximum subtype alignment will also have to be used as the alignment of stack frames, heap objects, and class-wide objects. Similarly, we do not recommend such large alignments for stack-allocated objects. 38.i

If the maximum default Alignment is 8 (say, Long_Float'Alignment = 8), then the implementation can refuse to accept stricter alignments for subtypes. This simplifies the generated code, since the compiler can align the stack and class-wide types to this maximum without a substantial waste of space (or time). 38.j

Note that the recommended level of support takes into account interactions between Size and Alignment. For example, on a 32-bit machine with 8-bit storage elements, where load and store instructions have to be aligned according to the size of the thing being loaded or stored, the implementation might accept an Alignment of 1 if the Size is 8, but might reject an Alignment of 1 if the Size is 32. On a machine where unaligned loads and stores are merely inefficient (as opposed to causing hardware traps), we would expect an Alignment of 1 to be supported for any Size. 38.k

Wording Changes from Ada 83

{*AI12-0005-1*} The nonnegative part is missing from RM83 (for mod_clauses, known in Ada 83 as alignment_clauses, which are an obsolete version of Alignment clauses). 38.l/5

Static Semantics

For a prefix X that denotes an object: 39/1

X'Size Denotes the size in bits of the representation of the object. The value of this attribute is of the type *universal_integer*. 40

Ramification: Note that Size is in bits even if Machine_Radix is 10. Each decimal digit (and the sign) is presumably represented as some number of bits. 40.a

Size may be specified for [stand-alone] objects via an attribute_definition_clause; the expression of such a clause shall be static and its value nonnegative. 41

Aspect Description for Size (object): Size in bits of an object. 41.a/3

Implementation Advice

{*AI95-00051-02*} The size of an array object should not include its bounds. 41.1/2

Implementation Advice: The Size of an array object should not include its bounds. 41.a.1/2

{*AI95-00051-02*} {*AI95-00291-02*} {*AI12-0445-1*} The recommended level of support for the Size attribute of objects is the same as for subtypes (see below), except that only a confirming Size clause is required to be supported for an aliased elementary object. 42/5

- *This paragraph was deleted.*{*AI95-00051-02*} 43/2

Static Semantics

For every subtype S: 44

S'Size If S is definite, denotes the size [(in bits)] that the implementation would choose for the following objects of subtype S: 45

- A record component of subtype S when the record type is packed. 46

47 - The formal parameter of an instance of Unchecked_Conversion that converts from subtype S to some other subtype.

48 If S is indefinite, the meaning is implementation defined. The value of this attribute is of the type *universal_integer*. The Size of an object is at least as large as that of its subtype, unless the object's Size is determined by a Size clause, a component_clause, or a Component_Size clause. Size may be specified for first subtypes via an attribute_definition_clause; the expression of such a clause shall be static and its value nonnegative.

48.a **Implementation defined:** The meaning of Size for indefinite subtypes.

48.b **Reason:** The effects of specifying the Size of a subtype are:

48.c - Unchecked_Conversion works in a predictable manner.

48.d - A composite type cannot be packed so tightly as to override the specified Size of a component's subtype.

48.e - Assuming the Implementation Advice is obeyed, if the specified Size allows independent addressability, then the Size of certain objects of the subtype should be equal to the subtype's Size. This applies to stand-alone objects and to components (unless a component_clause or a Component_Size clause applies).

48.f/3 {*AI05-0229-1*} A component_clause or a Component_Size clause can cause an object to be smaller than its subtype's specified size. The aspect Pack cannot; if a component subtype's size is specified, this limits how tightly the composite object can be packed.

48.g The Size of a class-wide (tagged) subtype is unspecified, because it's not clear what it should mean; it should certainly not depend on all of the descendants that happen to exist in a given program. Note that this cannot be detected at compile time, because in a generic unit, it is not necessarily known whether a given subtype is class-wide. It might raise an exception on some implementations.

48.h **Ramification:** A Size clause for a numeric subtype need not affect the underlying numeric type. For example, if I say:

48.i
```
type S is range 1..2;
for S'Size use 64;
```

48.j I am not guaranteed that S'Base'Last >= 2**63–1, nor that intermediate results will be represented in 64 bits.

48.k **Reason:** There is no need to complicate implementations for this sort of thing, because the right way to affect the base range of a type is to use the normal way of declaring the base range:

48.l
```
type Big is range -2**63 .. 2**63 - 1;
subtype Small is Big range 1..1000;
```

48.m **Ramification:** The Size of a large unconstrained subtype (e.g. String'Size) is likely to raise Constraint_Error, since it is a nonstatic expression of type *universal_integer* that might overflow the largest signed integer type. There is no requirement that the largest integer type be able to represent the size in bits of the largest possible object.

48.n/3 **Aspect Description for Size (subtype):** Size in bits of a subtype.

Implementation Requirements

49 In an implementation, Boolean'Size shall be 1.

Implementation Advice

50/5 {*AI95-00051-02*} {*AI12-0059-1*} If the Size of a subtype is nonconfirming and allows for efficient independent addressability (see 9.10) on the target architecture, then the Object_Size of the subtype should have the same value in the absence of an explicit specification of a different value.

Paragraphs 51 and 52 were moved to the Implementation Advice for attribute Object_Size.

52.a.1/5 **Implementation Advice:** If the Size of a subtype is nonconfirming and allows for efficient independent addressability, then the Object_Size of the subtype (unless otherwise specified) should equal the Size of the subtype.

52.a **Ramification:** Thus, on a typical 32-bit machine, "**for** S'Size **use** 32;" will guarantee that aliased objects of subtype S, and components whose subtype is S, will have Size = 32 (assuming the implementation chooses to obey this Implementation Advice). On the other hand, if one writes, "**for** S2'Size **use** 5;" then stand-alone objects of subtype S2 will typically have their Size rounded up to ensure independent addressability.

52.b Note that "**for** S'Size **use** 32;" does not cause things like formal parameters to have Size = 32 — the implementation is allowed to make all parameters be at least 64 bits, for example.

Note that "**for** S2'Size **use** 5;" requires record components whose subtype is S2 to be exactly 5 bits if the record type is packed. The same is not true of array components; their Size may be rounded up to the nearest factor of the word size. 52.c

Implementation Note: {*AI95-00291-02*} On most machines, arrays don't contain gaps between elementary components; if the Component_Size is greater than the Size of the component subtype, the extra bits are generally considered part of each component, rather than gaps between components. On the other hand, a record might contain gaps between elementary components, depending on what sorts of loads, stores, and masking operations are generally done by the generated code. 52.d/2

{*AI95-00291-02*} For an array, any extra bits stored for each elementary component will generally be part of the component — the whole point of storing extra bits is to make loads and stores more efficient by avoiding the need to mask out extra bits. The PDP-10 is one counter-example; since the hardware supports byte strings with a gap at the end of each word, one would want to pack in that manner. 52.e/2

Reason: {*AI12-0059-1*} We talk about the explicit specification of Object_Size so that we have specified what happens if both Object_Size and Size are specified incompatibly; we give priority to Object_Size. Note that the value of Size no longer has any direct effect on the Size of objects; what happens instead is that the value of Size can have an effect on the value of Object_Size in the absence of a specification for Object_Size, and it is always the value of Object_Size that determines the size of an object. 52.f/5

A Size clause on a composite subtype should not affect the internal layout of components. 53

Implementation Advice: A Size clause on a composite subtype should not affect the internal layout of components. 53.a.1/2

Reason: {*AI05-0229-1*} That's what Pack aspects, record_representation_clauses, and Component_Size clauses are for. 53.a/3

The recommended level of support for the Size attribute of subtypes is: 54

- {*AI12-0445-1*} The Size (if not specified) of a static discrete or fixed point subtype should be the number of bits necessary to represent each value belonging to the subtype using an unbiased representation, leaving space for a sign bit only if the subtype contains negative values. If such a subtype is a first subtype, then an implementation should support a specified Size for it that reflects this representation. 55/5

  Implementation Note: This applies to static enumeration subtypes, using the internal codes used to represent the values. 55.a

  For a two's-complement machine, this implies that for a static signed integer subtype S, if all values of S are in the range 0 .. 2^n–1, or all values of S are in the range $–2^{n–1}$ .. $2^{n–1}$–1, for some *n* less than or equal to the word size, then S'Size should be <= the smallest such *n*. For a one's-complement machine, it is the same except that in the second range, the lower bound "$–2^{n–1}$" is replaced by "$–2^{n–1}$+1". 55.b

  If an integer subtype (whether signed or unsigned) contains no negative values, the Size should not include space for a sign bit. 55.c

  Typically, the implementation will choose to make the Size of a subtype be exactly the smallest such *n*. However, it might, for example, choose a biased representation, in which case it could choose a smaller value. 55.d

  {*AI05-0229-1*} On most machines, it is in general not a good idea to pack (parts of) multiple stand-alone objects into the same storage element, because (1) it usually doesn't save much space, and (2) it requires locking to prevent tasks from interfering with each other, since separate stand-alone objects are independently addressable. Therefore, if S'Size = 2 on a machine with 8-bit storage elements, the size of a stand-alone object of subtype S will probably not be 2. It might, for example, be 8, 16 or 32, depending on the availability and efficiency of various machine instructions. The same applies to components of composite types, unless Pack, Component_Size, or record layout is specified. 55.e/3

  For an unconstrained discriminated object, if the implementation allocates the maximum possible size, then the Size attribute should return that maximum possible size. 55.f

  Ramification: The Size of an object X is not usually the same as that of its subtype S. If X is a stand-alone object or a parameter, for example, most implementations will round X'Size up to a storage element boundary, or more, so X'Size might be greater than S'Size. On the other hand, X'Size cannot be less than S'Size, even if the implementation can prove, for example, that the range of values actually taken on by X during execution is smaller than the range of S. 55.g

  For example, if S is a first integer subtype whose range is 0..3, S'Size will be probably be 2 bits, and components of packed composite types of this subtype will be 2 bits (assuming Storage_Unit is a multiple of 2), but stand-alone objects and parameters will probably not have a size of 2 bits; they might be rounded up to 32 bits, for example. On the other hand, Unchecked_Conversion will use the 2-bit size, even when converting a stand-alone object, as one would expect. 55.h

  Another reason for making the Size of an object bigger than its subtype's Size is to support the run-time detection of uninitialized variables. The implementation might add an extra value to a discrete subtype that represents the 55.i

uninitialized state, and check for this value on use. In some cases, the extra value will require an extra bit in the representation of the object. Such detection is not required by the language. If it is provided, the implementation has to be able to turn it off. For example, if the programmer gives a record_representation_clause or Component_Size clause that makes a component too small to allow the extra bit, then the implementation will not be able to perform the checking (not using this method, anyway).

55.j The fact that the size of an object is not necessarily the same as its subtype can be confusing:

55.k
```
type Device_Register is range 0..2**8 - 1;
for Device_Register'Size use 8; -- Confusing!
My_Device : Device_Register;
for My_Device'Address use To_Address(16#FF00#);
```

55.l/5 {*AI12-0005-1*} The programmer might think that My_Device'Size is 8, and that My_Device'Address points at an 8-bit location. However, this is not guaranteed to be true. In Ada 83 (and in Ada 95), My_Device'Size might well be 32, and My_Device'Address might well point at the high-order 8 bits of the 32-bit object, which are always all zero bits. If My_Device'Address is passed to an assembly language subprogram, based on the programmer's assumption, the program will not work properly.

55.m **Reason:** It is not reasonable to require that an implementation allocate exactly 8 bits to all objects of subtype Device_Register. For example, in many run-time models, stand-alone objects and parameters are always aligned to a word boundary. Such run-time models are generally based on hardware considerations that are beyond the control of the implementer. (It is reasonable to require that an implementation allocate exactly 8 bits to all components of subtype Device_Register, if packed.)

55.n **Ramification:** The correct way to write the above code is like this:

55.o
```
type Device_Register is range 0..2**8 - 1;
My_Device : Device_Register;
for My_Device'Size use 8;
for My_Device'Address use To_Address(16#FF00#);
```

55.p If the implementation cannot accept 8-bit stand-alone objects, then this will be illegal. However, on a machine where an 8-bit device register exists, the implementation will probably be able to accept 8-bit stand-alone objects. Therefore, My_Device'Size will be 8, and My_Device'Address will point at those 8 bits, as desired.

55.q If an object of subtype Device_Register is passed to a foreign language subprogram, it will be passed according to that subprogram's conventions. Most foreign language implementations have similar run-time model restrictions. For example, when passing to a C function, where the argument is of the C type char* (that is, pointer to char), the C compiler will generally expect a full word value, either on the stack, or in a register. It will *not* expect a single byte. Thus, Size clauses for subtypes really have nothing to do with passing parameters to foreign language subprograms.

56 - For a subtype implemented with levels of indirection, the Size should include the size of the pointers, but not the size of what they point at.

56.a **Ramification:** For example, if a task object is represented as a pointer to some information (including a task stack), then the size of the object should be the size of the pointer. The Storage_Size, on the other hand, should include the size of the stack.

56.1/2 - {*AI95-00051-02*} An implementation should support a Size clause for a discrete type, fixed point type, record type, or array type, subject to the following:

  56.2/5 - {*AI95-00051-02*} {*AI12-0444-1*} An implementation is not required to support a Size clause for a signed integer type specifying a Size greater than that of the largest signed integer type supported by the implementation in the absence of a size clause (that is, when the size is chosen by default). A corresponding limitation may be imposed for modular integer types, fixed point types, enumeration types, record types, and array types.

56.b/2 **Discussion:** {*AI95-00051-02*} Note that the "corresponding limitation" for a record or array type implies that an implementation may impose some reasonable maximum size for records and arrays (e.g. 2**32 bits), which is an upper bound ("capacity" limit) on the size, whether chosen by default or by being specified by the user. The largest size supported for records need not be the same as the largest size supported for arrays.

56.b.1/3 **Ramification:** {*AI05-0155-1*} Only Size clauses with a size greater than or equal to the Size that would be chosen by default may be safely presumed to be supported on nonstatic elementary subtypes. Implementations may choose to support smaller sizes, but only if the Size allows any value of the subtype to be represented, for any possible value of the bounds.

  56.3/5 - {*AI95-00291-02*} {*AI12-0444-1*} A nonconfirming size clause for the first subtype of a derived untagged by-reference type is not required to be supported.

Implementation Advice: The recommended level of support for the Size attribute should be followed. 56.c/2

Ramification: {*AI95-00291-02*} There is no recommendation to support any nonconfirming Size clauses for types not mentioned above. Remember that 13.1 requires support for confirming Size clauses for all types. 56.d/2

NOTE 5 Size is a subtype-specific attribute. 57

NOTE 6 {*AI05-0229-1*} A component_clause or Component_Size clause can override a specified Size. Aspect Pack cannot. 58/3

Inconsistencies With Ada 83

{*AI95-00114-01*} We specify the meaning of Size in much more detail than Ada 83. This is not technically an inconsistency, but it is in practice, as most Ada 83 compilers use a different definition for Size than is required here. This should have been documented more explicitly during the Ada 9X process. 58.a.1/2

Wording Changes from Ada 83

The requirement for a nonnegative value in a Size clause was not in RM83, but it's hard to see how it would make sense. For uniformity, we forbid negative sizes, rather than letting implementations define their meaning. 58.a

Static Semantics

{*AI12-0059-1*} For every subtype S: 58.1/5

S'Object_Size 58.2/5

{*AI12-0059-1*} If S is definite, denotes the size (in bits) of a stand-alone aliased object, or a component of subtype S in the absence of an aspect_specification or representation item that specifies the size of the object or component. If S is indefinite, the meaning is implementation-defined. The value of this attribute is of the type *universal_integer*. If not specified otherwise, the Object_Size of a subtype is at least as large as the Size of the subtype. Object_Size may be specified via an attribute_definition_clause; the expression of such a clause shall be static and its value nonnegative. All aliased objects with nominal subtype S have the size S'Object_Size. In the absence of an explicit specification, the Object_Size of a subtype S defined by a subtype_indication without a constraint, is that of the value of the Object_Size of the subtype denoted by the subtype_mark of the subtype_indication, at the point of this definition.

Implementation defined: The meaning of Object_Size for indefinite subtypes. 58.a.1/5

Ramification: We allow the specification of Object_Size for any subtype (*not* just first subtypes, as with other aspects). An implementation can, of course, put restrictions on which subtypes allow specification of Object_Size (as with any representation attribute). 58.b/5

Implementation Advice

{*AI12-0059-1*} If S is a definite first subtype and S'Object_Size is not specified, S'Object_Size should be the smallest multiple of the storage element size larger than or equal to S'Size that is consistent with the alignment of S. 58.3/5

Implementation Advice: If S is a definite first subtype for which Object_Size is not specified, S'Object_Size should be the smallest multiple of the storage element size larger than or equal to S'Size that is consistent with the alignment of S. 58.b.1/5

Reason: Many implementations “round up” allocations to the nearest multiple of the alignment. For instance, this example appears in the GNAT documentation: 58.c/5

[Given] a record containing an integer and a character: 58.d/5

```
type Rec is record                                                    58.e/5
   I : Integer;
   C : Character;
end record;
```

will have a size of 40 (that is Rec'Size will be 40). The alignment will be 4, because of the integer field, and so the default size of record objects for this type will be 64 (8 bytes). 58.f/5

We purposely used the vague phrase “consistent with the alignment of S” so that implementations that do not round up allocations (just using padding to provide alignment) are not required to do any rounding up. 58.g/5

58.4/5 {*AI12-0059-1*} If X denotes an object (including a component) of subtype S, X'Size should equal S'Object_Size, unless:

58.5/5 • X'Size is specified; or

58.6/5 • X is a nonaliased stand-alone object; or

58.7/5 • The size of X is determined by a component_clause or Component_Size clause; or

58.8/5 • The type containing component X is packed.

58.g.1/5 **Implementation Advice:** The Size of most objects of a subtype should equal the Object_Size of the subtype.

58.9/5 {*AI12-0059-1*} An Object_Size clause on a composite type should not affect the internal layout of components.

58.g.2/5 **Implementation Advice:** An Object_Size clause on a composite type should not affect the internal layout of components.

58.10/5 {*AI12-0059-1*} The recommended level of support for the Object_Size attribute of subtypes is:

58.11/5 • If S is a static signed integer subtype, the implementation should support the specification of S'Object_Size to match the size of any signed integer base subtype provided by the implementation that is no smaller than S'Size. Corresponding support is expected for modular integer subtypes, fixed point subtypes, and enumeration subtypes.

58.h/5 **Ramification:** The intent is that a compiler need support only those Object_Sizes for integer subtypes that it might select for an integer type declaration. Similarly for the other kinds of subtypes listed.

58.12/5 • If S is an array or record subtype with static constraints and S is not a first subtype of a derived untagged by-reference type, the implementation should support the specification of S'Object_Size to be any multiple of the storage element size that is consistent with the alignment of S, that is no smaller than S'Size, and that is no larger than that of the largest composite subtype supported by the implementation.

58.i/5 **Discussion:** Any extra bits required this way will be padding bits. Unlike elementary objects, padding bits can be considered part of composite objects.

58.13/5 • If S is some other subtype, only confirming specifications of Object_Size are required to be supported.

58.i.1/5 **Implementation Advice:** The recommended level of support for the Object_Size attribute should be followed.

Static Semantics

59/1 For a prefix T that denotes a task object [(after any implicit dereference)]:

60/3 T'Storage_Size

{*AI05-0229-1*} Denotes the number of storage elements reserved for the task. The value of this attribute is of the type *universal_integer*. The Storage_Size includes the size of the task's stack, if any. The language does not specify whether or not it includes other storage associated with the task (such as the “task control block” used by some implementations.) If the aspect Storage_Size is specified for the type of the object, the value of the Storage_Size attribute is at least the value determined by the aspect.

60.a **Ramification:** The value of this attribute is never negative, since it is impossible to “reserve” a negative number of storage elements.

60.b If the implementation chooses to allocate an initial amount of storage, and then increase this as needed, the Storage_Size cannot include the additional amounts (assuming the allocation of the additional amounts can raise Storage_Error); this is inherent in the meaning of “reserved”.

60.c The implementation is allowed to allocate different amounts of storage for different tasks of the same subtype.

60.d Storage_Size is also defined for access subtypes — see 13.11.

61/3 {*AI95-0229-1*} [Aspect Storage_Size specifies the amount of storage to be reserved for the execution of a task.]

Paragraphs 62 through 65 were moved to Annex J, "Obsolescent Features".

Static Semantics

{*AI05-0229-1*} {*AI05-0269-1*} For a task type (including the anonymous type of a single_task_declaration), the following language-defined representation aspect may be specified: 65.1/3

Storage_Size 65.2/3

The Storage_Size aspect is an expression, which shall be of any integer type.

To be honest: This definition somewhat conflicts with the "automatic" one for the obsolescent attribute Storage_Size (which can be specified). The only difference is where the given expression is evaluated. We intend for the above definition to supersede that "automatic" definition for this attribute. 65.a/3

Ramification: Note that the value of the Storage_Size aspect *is* an expression; it is not the *value* of an expression. The expression is evaluated for each object of the type (see below). 65.b/3

Aspect Description for Storage_Size (task): Size in storage elements reserved for a task type or single task object. 65.c/3

Legality Rules

{*AI05-0229-1*} The Storage_Size aspect shall not be specified for a task interface type. 65.3/3

Dynamic Semantics

{*AI05-0229-1*} When a task object is created, the expression (if any) associated with the Storage_Size aspect of its type is evaluated; the Storage_Size attribute of the newly created task object is at least the value of the expression. 66/3

Ramification: The implementation is allowed to round up a specified Storage_Size amount. For example, if the implementation always allocates in chunks of 4096 bytes, the number 200 might be rounded up to 4096. Also, if the user specifies a negative number, the implementation has to normalize this to 0, or perhaps to a positive number. 66.a

{*AI05-0229-1*} If the Storage_Size aspect is not specified for the type of the task object, the value of the Storage_Size attribute is unspecified. 66.b/3

At the point of task object creation, or upon task activation, Storage_Error is raised if there is insufficient free storage to accommodate the requested Storage_Size. 67

Static Semantics

For a prefix X that denotes an array subtype or array object [(after any implicit dereference)]: 68/1

X'Component_Size 69

Denotes the size in bits of components of the type of X. The value of this attribute is of type *universal_integer*.

Component_Size may be specified for array types via an attribute_definition_clause; the expression of such a clause shall be static, and its value nonnegative. 70

Implementation Note: The intent is that the value of X'Component_Size is always nonnegative. If the array is stored "backwards" in memory (which might be caused by an implementation-defined pragma), X'Component_Size is still positive. 70.a

Ramification: For an array object A, A'Component_Size = A(I)'Size for any index I. 70.b

Aspect Description for Component_Size: Size in bits of a component of an array type. 70.c/3

Implementation Advice

The recommended level of support for the Component_Size attribute is: 71

- {*AI12-0444-1*} An implementation is not required to support specified Component_Sizes that are less than the Size of the component subtype. 72/5
- {*AI05-0229-1*} An implementation should support specified Component_Sizes that are factors and multiples of the word size. For such Component_Sizes, the array should contain no gaps 73/3

between components. For other Component_Sizes (if supported), the array should contain no gaps between components when Pack is also specified; the implementation should forbid this combination in cases where it cannot support a no-gaps representation.

73.a/3 **Ramification:** {*AI05-0229-1*} For example, if Storage_Unit = 8, and Word_Size = 32, then the user is allowed to specify a Component_Size of 1, 2, 4, 8, 16, and 32, with no gaps. In addition, *n**32 is allowed for positive integers *n*, again with no gaps. If the implementation accepts Component_Size = 3, then it might allocate 10 components per word, with a 2-bit gap at the end of each word (unless Pack is also specified), or it might not have any internal gaps at all. (There can be gaps at either end of the array.)

73.b/2 **Implementation Advice:** The recommended level of support for the Component_Size attribute should be followed.

Static Semantics

73.1/3 {*AI05-0191-1*} For a prefix X that denotes an object:

73.2/4 X'Has_Same_Storage

{*AI05-0191-1*} X'Has_Same_Storage denotes a function with the following specification:

73.3/3
```
function X'Has_Same_Storage (Arg : any_type)
  return Boolean
```

73.4/4 {*AI05-0191-1*} {*AI05-0264-1*} {*AI12-0077-1*} The actual parameter shall be a name that denotes an object. The object denoted by the actual parameter can be of any type. This function evaluates the names of the objects involved. It returns True if the representation of the object denoted by the actual parameter occupies exactly the same bits as the representation of the object denoted by X and the objects occupy at least one bit; otherwise, it returns False.

73.c/3 **Discussion:** Has_Same_Storage means that, if the representation is contiguous, the objects sit at the same address and occupy the same length of memory.

73.5/3 {*AI05-0191-1*} For a prefix X that denotes an object:

73.6/3 X'Overlaps_Storage

{*AI05-0191-1*} X'Overlaps_Storage denotes a function with the following specification:

73.7/3
```
function X'Overlaps_Storage (Arg : any_type)
  return Boolean
```

73.8/3 {*AI05-0191-1*} {*AI05-0264-1*} The actual parameter shall be a name that denotes an object. The object denoted by the actual parameter can be of any type. This function evaluates the names of the objects involved and returns True if the representation of the object denoted by the actual parameter shares at least one bit with the representation of the object denoted by X; otherwise, it returns False.

73.9/3 NOTE 7 {*AI05-0191-1*} X'Has_Same_Storage(Y) implies X'Overlaps_Storage(Y).

73.10/3 NOTE 8 {*AI05-0191-1*} X'Has_Same_Storage(Y) and X'Overlaps_Storage(Y) are not considered to be reads of X and Y.

Static Semantics

73.11/3 {*8652/0009*} {*AI95-00137-01*} {*AI05-0183-1*} The following type-related operational attribute is defined: External_Tag.

74/1 {*8652/0009*} {*AI95-00137-01*} For every subtype S of a tagged type *T* (specific or class-wide):

75/3 S'External_Tag

{*8652/0040*} {*AI95-00108-01*} {*AI05-0092-1*} S'External_Tag denotes an external string representation for S'Tag; it is of the predefined type String. External_Tag may be specified for a specific tagged type via an attribute_definition_clause; the expression of such a clause shall be static. The default external tag representation is implementation defined. See 13.13.2. The value of External_Tag is never inherited[; the default value is always used unless a new value is directly specified for a type].

75.a **Implementation defined:** The default external representation for a type tag.

Aspect Description for External_Tag: Unique identifier for a tagged type in streams. 75.b/3

Dynamic Semantics

{*AI05-0113-1*} If a user-specified external tag S'External_Tag is the same as T'External_Tag for some other tagged type declared by a different declaration in the partition, Program_Error is raised by the elaboration of the attribute_definition_clause. 75.1/3

Ramification: This rule does not depend on the visibility of the other tagged type, but it does depend on the existence of the other tagged type. The other tagged type could have the default external tag or a user-specified external tag. 75.c/3

This rule allows the same declaration to be elaborated multiple times. In that case, different types could have the same external tag. If that happens, Internal_Tag would return some unspecified tag, and Descendant_Tag probably would return the intended tag (using the given ancestor to determine which type is intended). However, in some cases (such as multiple instantiations of a derived tagged type declared in a generic body), Tag_Error might be raised by Descendant_Tag if multiple types are identified. 75.d/3

Note that while there is a race condition inherent in this definition (which attribute_definition_clause raises Program_Error depends on the order of elaboration), it doesn't matter as a program with two such clauses is simply wrong. Two types that both come from the same declaration are allowed, as noted previously. 75.e/3

Implementation Requirements

In an implementation, the default external tag for each specific tagged type declared in a partition shall be distinct, so long as the type is declared outside an instance of a generic body. If the compilation unit in which a given tagged type is declared, and all compilation units on which it semantically depends, are the same in two different partitions, then the external tag for the type shall be the same in the two partitions. What it means for a compilation unit to be the same in two different partitions is implementation defined. At a minimum, if the compilation unit is not recompiled between building the two different partitions that include it, the compilation unit is considered the same in the two partitions. 76

Implementation defined: What determines whether a compilation unit is the same in two different partitions. 76.a

Reason: These requirements are important because external tags are used for input/output of class-wide types. These requirements ensure that what is written by one program can be read back by some other program so long as they share the same declaration for the type (and everything it depends on). 76.b

The user may specify the external tag if (s)he wishes its value to be stable even across changes to the compilation unit in which the type is declared (or changes in some unit on which it depends). 76.c

{*AI95-00114-01*} We use a String rather than a Stream_Element_Array to represent an external tag for portability. 76.d/2

Ramification: Note that the characters of an external tag need not all be graphic characters. In other words, the external tag can be a sequence of arbitrary 8-bit bytes. 76.e

Implementation Permissions

{*AI05-0113-1*} If a user-specified external tag S'External_Tag is the same as T'External_Tag for some other tagged type declared by a different declaration in the partition, the partition may be rejected. 76.1/3

Ramification: This is, in general, a post-compilation check. This permission is intended for implementations that do link-time construction of the external tag lookup table; implementations that dynamically construct the table will likely prefer to raise Program_Error upon elaboration of the problem construct. We don't want this check to require any implementation complexity, as it will be very rare that there would be a problem. 76.f/3

NOTE 9 {*AI95-00270-01*} The following language-defined attributes are specifiable, at least for some of the kinds of entities to which they apply: Address, Alignment, Bit_Order, Component_Size, External_Tag, Input, Machine_Radix, Output, Read, Size, Small, Storage_Pool, Storage_Size, Stream_Size, and Write. 77/2

NOTE 10 It follows from the general rules in 13.1 that if one writes "**for** X'Size **use** Y;" then the X'Size attribute_reference will return Y (assuming the implementation allows the Size clause). The same is true for all of the specifiable attributes except Storage_Size. 78

Ramification: An implementation may specify that an implementation-defined attribute is specifiable for certain entities. This follows from the fact that the semantics of implementation-defined attributes is implementation defined. An implementation is not allowed to make a language-defined attribute specifiable if it isn't. 78.a

Examples

79 *Examples of attribute definition clauses:*

80
```
Byte : constant := 8;
Page : constant := 2**12;
```

81
```
type Medium is range 0 .. 65_000;
for Medium'Size use 2*Byte;
for Medium'Alignment use 2;
Device_Register : Medium;
for Device_Register'Size use Medium'Size;
for Device_Register'Address use
   System.Storage_Elements.To_Address(16#FFFF_0020#);
```

82
```
type Short is delta 0.01 range -100.0 .. 100.0;
for Short'Size use 15;
```

83
```
for Car_Name'Storage_Size use -- specify access type's storage pool size
        2000*((Car'Size/System.Storage_Unit) +1); -- approximately 2000 cars
```

84/2
```
{AI95-00441-01} function My_Input(Stream : not null access
Ada.Streams.Root_Stream_Type'Class)
   return T;
for T'Input use My_Input; -- see 13.13.2
```

85/5 {*AI12-0452-1*} In the Size clause for Short, fifteen bits is the minimum necessary, since the type definition requires Short'Small <= 2**(–7).

Extensions to Ada 83

86.a The syntax rule for length_clause is replaced with the new syntax rule for attribute_definition_clause, and it is modified to allow a name (as well as an expression).

Wording Changes from Ada 83

86.b The syntax rule for attribute_definition_clause now requires that the prefix of the attribute be a local_name; in Ada 83 this rule was stated in the text.

86.c/2 {*AI95-00114-01*} In Ada 83, the relationship between a aspect_clause specifying a certain aspect and an attribute that queried that aspect was unclear. In Ada 95, they are the same, except for certain explicit exceptions.

Wording Changes from Ada 95

86.d/2 {*8652/0009*} {*AI95-00137-01*} **Corrigendum:** Added wording to specify for each attribute whether it is an operational or representation attribute.

86.e/2 {*8652/0040*} {*AI95-00108-01*} **Corrigendum:** Added wording to specify that External_Tag is never inherited.

86.f/2 {*AI95-00051-01*} {*AI95-00291-01*} Adjusted the Recommended Level of Support for Alignment to eliminate nonsense requirements and to ensure that useful capabilities are required.

86.g/2 {*AI95-00051-01*} {*AI95-00291-01*} Adjusted the Recommended Level of Support for Size to eliminate nonsense requirements and to ensure that useful capabilities are required. Also eliminated any dependence on whether an aspect was specified (a confirming representation item should not affect the semantics).

86.h/2 {*AI95-00133-01*} Added the definition of machine scalar.

86.i/2 {*AI95-00247-01*} Removed the requirement that specified alignments for a composite type cannot override those for their components, because it was never intended to apply to components whose location was specified with a representation item. Moreover, it causes a difference in legality when a confirming alignment is specified for one of the composite types.

86.j/2 {*AI95-00291-02*} Removed recommended level of support rules about types with by-reference and aliased parts, because there are now blanket rules covering all recommended level of support rules.

86.k/2 {*AI95-00291-02*} Split the definition of Alignment for subtypes and for objects. This simplified the wording and eliminated confusion about which rules applied to objects, which applied to subtypes, and which applied to both.

Inconsistencies With Ada 2005

86.l/3 {*AI95-0095-1*} **Correction:** An address attribute with a prefix of a generic formal subprogram whose actual parameter has convention Intrinsic now raises Program_Error. Since it is unlikely that such an attribute would have done anything

useful (a subprogram with convention Intrinsic is not expected to have a normal subprogram body), it is highly unlikely that any existing programs would notice the difference, and any that do probably are buggy.

{*AI95-0113-1*} **Correction:** User-specified external tags that conflict with other external tags raise Program_Error (or are optionally illegal). This was legal and did not raise an exception in the past, although the effects were not defined. So while a program might depend on such behavior, the results were not portable (even to different versions of the same implementation). Such programs should be rare. 86.m/3

Incompatibilities With Ada 2005

{*AI05-0095-1*} **Correction:** An address attribute with a prefix of a subprogram with convention Intrinsic is now illegal. Such attributes are very unlikely to have provided a useful answer (the intended meaning of convention Intrinsic is that there is no actual subprogram body for the operation), so this is highly unlikely to affect any existing programs unless they have a hidden bug. 86.n/3

Extensions to Ada 2005

{*AI05-0191-1*} Attributes Has_Same_Storage and Overlaps_Storage are new. 86.o/3

{*AI05-0229-1*} Aspect Storage_Size is new; pragma Storage_Size is now obsolescent, joining attribute Storage_Size for task types. 86.p/3

Wording Changes from Ada 2005

{*AI05-0009-1*} **Correction:** Improved the description of erroneous execution for address clauses to make it clear that specifying an address inappropriate for the entity will lead to erroneous execution. 86.q/3

{*AI05-0116-1*} **Correction:** Added Implementation Advice for the alignment of class-wide types. 86.r/3

Extensions to Ada 2012

{*AI12-0059-1*} Attribute Object_Size is new. 86.s/5

Wording Changes from Ada 2012

{*AI12-0070-1*} **Corrigendum:** Clarified the behavior of Has_Same_Storage when 'Size = 0. 86.t/4

13.4 Enumeration Representation Clauses

[An enumeration_representation_clause specifies the internal codes for enumeration literals.] 1

Syntax

enumeration_representation_clause ::= 2
  for *first_subtype*_local_name **use** enumeration_aggregate;

enumeration_aggregate ::= array_aggregate 3

Name Resolution Rules

The enumeration_aggregate shall be written as a one-dimensional array_aggregate, for which the index subtype is the unconstrained subtype of the enumeration type, and each component expression is expected to be of any integer type. 4

Ramification: The "full coverage rules" for aggregates applies. An **others** is not allowed — there is no applicable index constraint in this context. 4.a

Legality Rules

The *first_subtype*_local_name of an enumeration_representation_clause shall denote an enumeration subtype. 5

Ramification: As for all type-related representation items, the local_name is required to denote a first subtype. 5.a

{*AI95-00287-01*} Each component of the array_aggregate shall be given by an expression rather than a <>. The expressions given in the array_aggregate shall be static, and shall specify distinct integer codes 6/2

for each value of the enumeration type; the associated integer codes shall satisfy the predefined ordering relation of the type.

6.a **Reason:** Each value of the enumeration type has to be given an internal code, even if the first subtype of the enumeration type is constrained to only a subrange (this is only possible if the enumeration type is a derived type). This "full coverage" requirement is important because one may refer to Enum'Base'First and Enum'Base'Last, which need to have defined representations.

Static Semantics

7 An enumeration_representation_clause specifies the *coding* aspect of representation. The coding consists of the *internal code* for each enumeration literal, that is, the integral value used internally to represent each literal.

7.a/3 **Aspect Description for Coding:** Internal representation of enumeration literals. Specified by an enumeration_representation_clause, not by an aspect_specification.

Implementation Requirements

8 For nonboolean enumeration types, if the coding is not specified for the type, then for each value of the type, the internal code shall be equal to its position number.

8.a **Reason:** This default representation is already used by all known Ada compilers for nonboolean enumeration types. Therefore, we make it a requirement so users can depend on it, rather than feeling obliged to supply for every enumeration type an enumeration representation clause that is equivalent to this default rule.

8.b **Discussion:** For boolean types, it is relatively common to use all ones for True, and all zeros for False, since some hardware supports that directly. Of course, for a one-bit Boolean object (like in a packed array), False is presumably zero and True is presumably one (choosing the reverse would be extremely unfriendly!).

Implementation Advice

9 The recommended level of support for enumeration_representation_clauses is:

10/5 - {*AI12-0444-1*} An implementation should support at least the internal codes in the range System.Min_Int .. System.Max_Int. An implementation is not required to support enumeration_representation_clauses for boolean types.

10.a **Ramification:** The implementation may support numbers outside the above range, such as numbers greater than System.Max_Int. See AI83-00564.

10.b **Reason:** The benefits of specifying the internal coding of a boolean type do not outweigh the implementation costs. Consider, for example, the implementation of the logical operators on a packed array of booleans with strange internal codes. It's implementable, but not worth it.

10.c/2 **Implementation Advice:** The recommended level of support for enumeration_representation_clauses should be followed.

Static Semantics

10.1/5 {*AI12-0237-1*} For every discrete subtype S, the following attributes are defined:

10.2/5 S'Enum_Rep

{*AI12-0237-1*} S'Enum_Rep denotes a function with the following specification:

10.3/5
```
function S'Enum_Rep (Arg : S'Base) return universal_integer
```

10.4/5 This function returns the representation value of the value of Arg, as a value of type *universal_integer*. The *representation value* is the internal code specified in an enumeration representation clause, if any, for the type corresponding to the value of Arg, and otherwise is the position number of the value.

10.5/5 S'Enum_Val

{*AI12-0237-1*} S'Enum_Val denotes a function with the following specification:

10.6/5
```
function S'Enum_Val (Arg : universal_integer) return S'Base
```

This function returns a value of the type of S whose representation value equals the value of Arg. For the evaluation of a call on S'Enum_Val, if there is no value in the base range of its type with the given representation value, Constraint_Error is raised. 10.7/5

Reason: We define these on all discrete types so that they can be used inside of a generic unit on a subtype of a generic formal discrete type. They're not useful on integer types (they have the same effect as S'Pos and S'Val). 10.d/5

NOTE {*8652/0009*} {*AI95-00137-01*} {*AI05-0299-1*} {*AI12-0237-1*} {*AI12-0442-1*} Attribute Enum_Rep can be used to query the internal codes used for an enumeration type; attribute Enum_Val can be used to convert from an internal code to an enumeration value. The other attributes of the type, such as Succ, Pred, and Pos, are unaffected by an enumeration_representation_clause. For example, Pos always returns the position number, *not* an internal integer code that was specified in an enumeration_representation_clause. 11/5

Discussion: Suppose the enumeration type in question is derived: 11.a

```
type T1 is (Red, Green, Blue);
subtype S1 is T1 range Red .. Green;
type S2 is new S1;
for S2 use (Red => 10, Green => 20, Blue => 30);
```
11.b

{*8652/0009*} {*AI95-00137-01*} The enumeration_representation_clause has to specify values for all enumerals, even ones that are not in S2 (such as Blue). The Base attribute can be used to get at these values. For example: 11.c/1

```
for I in S2'Base loop
    ... -- When I equals Blue, the internal code is 30.
end loop;
```
11.d

We considered allowing or requiring "**for** S2'Base **use** ..." in cases like this, but it didn't seem worth the trouble. 11.e

Examples

{*AI12-0312-1*} *Examples of enumeration representation clauses:* 12/5

```
type Mix_Code is (ADD, SUB, MUL, LDA, STA, STZ);
```
13

```
for Mix_Code use
   (ADD => 1, SUB => 2, MUL => 3, LDA => 8, STA => 24, STZ =>33);
```
14

{*AI12-0312-1*} -- *See 3.5.2.*

```
for Roman_Digit use ('I' => 1,
                     'V' => 5,
                     'X' => 10,
                     'L' => 50,
                     'C' => 100,
                     'D' => 500,
                     'M' => 1000);
```
15/5

{*AI12-0312-1*} -- *For an example of the use of attribute Enum_Rep, see 4.2.1.* 16/5

Extensions to Ada 83

As in other similar contexts, Ada 95 allows expressions of any integer type, not just expressions of type *universal_integer*, for the component expressions in the enumeration_aggregate. The preference rules for the predefined operators of *root_integer* eliminate any ambiguity. 16.a

For portability, we now require that the default coding for an enumeration type be the "obvious" coding using position numbers. This is satisfied by all known implementations. 16.b

Wording Changes from Ada 95

{*8652/0009*} {*AI95-00137-01*} **Corrigendum:** Updated to reflect that we no longer have something called representation_clause. 16.c/2

{*AI95-00287-01*} Added wording to prevent the use of <> in a enumeration_representation_clause. (<> is newly added to array_aggregates.) 16.d/2

Extensions to Ada 2012

{*AI12-0237-1*} Attributes Enum_Rep and Enum_Val are new. 16.e/5

13.5 Record Layout

1 The *(record) layout* aspect of representation consists of the *storage places* for some or all components, that is, storage place attributes of the components. The layout can be specified with a record_representation_clause.

13.5.1 Record Representation Clauses

1 [A record_representation_clause specifies the storage representation of records and record extensions, that is, the order, position, and size of components (including discriminants, if any).]

Language Design Principles

1.a/2 {*AI95-00114-01*} It should be feasible for an implementation to use negative offsets in the representation of composite types. However, no implementation should be forced to support negative offsets. Therefore, in the interest of uniformity, negative offsets should be disallowed in record_representation_clauses.

Syntax

2/5 {*AI12-0213-1*} record_representation_clause ::=
for *first_subtype*_local_name **use**
record [mod_clause]
{component_clause}
end record [local_name];

3 component_clause ::=
*component*_local_name **at** position **range** first_bit .. last_bit;

4 position ::= *static*_expression

5 first_bit ::= *static*_simple_expression

6 last_bit ::= *static*_simple_expression

6.a **Reason:** First_bit and last_bit need to be simple_expression instead of expression for the same reason as in range (see 3.5, “Scalar Types”).

6.1/5 {*AI12-0213-1*} If a local_name appears at the end of the record_representation_clause, it shall repeat the *first_subtype*_local_name.

Name Resolution Rules

7 Each position, first_bit, and last_bit is expected to be of any integer type.

7.a **Ramification:** These need not have the same integer type.

Legality Rules

8/2 {*AI95-00436-01*} The *first_subtype*_local_name of a record_representation_clause shall denote a specific record or record extension subtype.

8.a **Ramification:** As for all type-related representation items, the local_name is required to denote a first subtype.

9 If the *component*_local_name is a direct_name, the local_name shall denote a component of the type. For a record extension, the component shall not be inherited, and shall not be a discriminant that corresponds to a discriminant of the parent type. If the *component*_local_name has an attribute_designator, the direct_name of the local_name shall denote either the declaration of the type or a component of the type, and the attribute_designator shall denote an implementation-defined implicit component of the type.

The position, first_bit, and last_bit shall be static expressions. The value of position and first_bit shall be nonnegative. The value of last_bit shall be no less than first_bit – 1. 10

Ramification: A component_clause such as "X **at** 4 **range** 0..–1;" is allowed if X can fit in zero bits. 10.a

{*AI95-00133-01*} If the nondefault bit ordering applies to the type, then either: 10.1/2

- the value of last_bit shall be less than the size of the largest machine scalar; or 10.2/2
- the value of first_bit shall be zero and the value of last_bit + 1 shall be a multiple of System.Storage_Unit. 10.3/2

At most one component_clause is allowed for each component of the type, including for each discriminant (component_clauses may be given for some, all, or none of the components). Storage places within a component_list shall not overlap, unless they are for components in distinct variants of the same variant_part. 11

A name that denotes a component of a type is not allowed within a record_representation_clause for the type, except as the *component_*local_name of a component_clause. 12

Reason: It might seem strange to make the record_representation_clause part of the declarative region, and then disallow mentions of the components within almost all of the record_representation_clause. The alternative would be to treat the *component_*local_name like a formal parameter name in a subprogram call (in terms of visibility). However, this rule would imply slightly different semantics, because (given the actual rule) the components can hide other declarations. This was the rule in Ada 83, and we see no reason to change it. The following, for example, was and is illegal: 12.a

```
type T is
    record
        X : Integer;
    end record;
X : constant := 31; -- Same defining name as the component.
for T use
    record
        X at 0 range 0..X; -- Illegal!
    end record;
```

12.b

The component X hides the named number X throughout the record_representation_clause. 12.c

Static Semantics

{*AI95-00133-01*} A record_representation_clause (without the mod_clause) specifies the layout. 13/2

Aspect Description for Layout (record): Layout of record components. Specified by a record_representation_clause, not by an aspect_specification. 13.a/3

Aspect Description for Record layout: See Layout. 13.b/3

{*AI95-00133-01*} If the default bit ordering applies to the type, the position, first_bit, and last_bit of each component_clause directly specify the position and size of the corresponding component. 13.1/2

{*AI95-00133-01*} {*AI05-0264-1*} If the nondefault bit ordering applies to the type, then the layout is determined as follows: 13.2/3

- the component_clauses for which the value of last_bit is greater than or equal to the size of the largest machine scalar directly specify the position and size of the corresponding component; 13.3/2
- for other component_clauses, all of the components having the same value of position are considered to be part of a single machine scalar, located at that position; this machine scalar has a size which is the smallest machine scalar size larger than the largest last_bit for all component_clauses at that position; the first_bit and last_bit of each component_clause are then interpreted as bit offsets in this machine scalar. 13.4/2

This paragraph was deleted.{*AI95-00133-01*} 13.c/2

Ramification: A component_clause also determines the value of the Size attribute of the component, since this attribute is related to First_Bit and Last_Bit. 13.d

14 [A record_representation_clause for a record extension does not override the layout of the parent part;] if the layout was specified for the parent type, it is inherited by the record extension.

Implementation Permissions

15 An implementation may generate implementation-defined components (for example, one containing the offset of another component). An implementation may generate names that denote such implementation-defined components; such names shall be implementation-defined attribute_references. An implementation may allow such implementation-defined names to be used in record_representation_clauses. An implementation can restrict such component_clauses in any manner it sees fit.

15.a **Implementation defined:** Implementation-defined components.

15.b **Ramification:** Of course, since the semantics of implementation-defined attributes is implementation defined, the implementation need not support these names in all situations. They might be purely for the purpose of component_clauses, for example. The visibility rules for such names are up to the implementation.

15.c We do not allow such component names to be normal identifiers — that would constitute blanket permission to do all kinds of evil things.

15.d **Discussion:** Such implementation-defined components are known in the vernacular as “dope”. Their main purpose is for storing offsets of components that depend on discriminants.

16 If a record_representation_clause is given for an untagged derived type, the storage place attributes for all of the components of the derived type may differ from those of the corresponding components of the parent type, even for components whose storage place is not specified explicitly in the record_representation_clause.

16.a **Reason:** This is clearly necessary, since the whole record may need to be laid out differently.

Implementation Advice

17 The recommended level of support for record_representation_clauses is:

17.1/2 • {*AI95-00133-01*} An implementation should support machine scalars that correspond to all of the integer, floating point, and address formats supported by the machine.

18 • An implementation should support storage places that can be extracted with a load, mask, shift sequence of machine code, and set with a load, shift, mask, store sequence, given the available machine instructions and run-time model.

19 • A storage place should be supported if its size is equal to the Size of the component subtype, and it starts and ends on a boundary that obeys the Alignment of the component subtype.

20/2 • {*AI95-00133-01*} For a component with a subtype whose Size is less than the word size, any storage place that does not cross an aligned word boundary should be supported.

20.a **Reason:** The above recommendations are sufficient to define interfaces to most interesting hardware. This causes less implementation burden than the definition in ACID, which requires arbitrary bit alignments of arbitrarily large components. Since the ACID definition is neither enforced by the ACVC, nor supported by all implementations, it seems OK for us to weaken it.

21 • An implementation may reserve a storage place for the tag field of a tagged type, and disallow other components from overlapping that place.

21.a **Ramification:** Similar permission for other dope is not granted.

22/5 • {*AI12-0444-1*} An implementation is not required to support a component_clause for a component of an extension part if the storage place is not after the storage places of all components of the parent type, whether or not those storage places had been specified.

22.a **Reason:** These restrictions are probably necessary if block equality operations are to be feasible for class-wide types. For block comparison to work, the implementation typically has to fill in any gaps with zero (or one) bits. If a “gap” in the parent type is filled in with a component in a type extension, then this won't work when a class-wide object is passed by reference, as is required.

Implementation Advice: The recommended level of support for record_representation_clauses should be followed. 22.b/2

NOTE If no component_clause is given for a component, then the choice of the storage place for the component is left to the implementation. If component_clauses are given for all components, the record_representation_clause completely specifies the representation of the type and will be obeyed exactly by the implementation. 23

Ramification: The visibility rules prevent the name of a component of the type from appearing in a record_representation_clause at any place *except* for the *component*_local_name of a component_clause. However, since the record_representation_clause is part of the declarative region of the type declaration, the component names hide outer homographs throughout. 23.a

{*8652/0009*} {*AI95-00137-01*} A record_representation_clause cannot be given for a protected type, even though protected types, like record types, have components. The primary reason for this rule is that there is likely to be too much dope in a protected type — entry queues, bit maps for barrier values, etc. In order to control the representation of the user-defined components, simply declare a record type, give it a record_representation_clause, and give the protected type one component whose type is the record type. Alternatively, if the protected object is protecting something like a device register, it makes more sense to keep the thing being protected outside the protected object (possibly with a pointer to it in the protected object), in order to keep implementation-defined components out of the way. 23.b/1

Examples

Example of specifying the layout of a record type: 24

```
Word : constant := 4;  -- storage element is byte, 4 bytes per word
```
25

```
type State         is (A,M,W,P);
type Mode          is (Fix, Dec, Exp, Signif);
```
26

```
{AI12-0178-1} type Byte_Mask     is array (0..7)  of Boolean with Component_Size =>
1;
type State_Mask    is array (State) of Boolean with Component_Size => 1;
type Mode_Mask     is array (Mode)  of Boolean with Component_Size => 1;
```
27/5

```
type Program_Status_Word is
  record
      System_Mask        : Byte_Mask;
      Protection_Key     : Integer range 0 .. 3;
      Machine_State      : State_Mask;
      Interrupt_Cause    : Interruption_Code;
      Ilc                : Integer range 0 .. 3;
      Cc                 : Integer range 0 .. 3;
      Program_Mask       : Mode_Mask;
      Inst_Address       : Address;
end record;
```
28

```
for Program_Status_Word use
  record
      System_Mask      at 0*Word range 0  .. 7;
      Protection_Key   at 0*Word range 10 .. 11; -- bits 8,9 unused
      Machine_State    at 0*Word range 12 .. 15;
      Interrupt_Cause  at 0*Word range 16 .. 31;
      Ilc              at 1*Word range 0  .. 1;  -- second word
      Cc               at 1*Word range 2  .. 3;
      Program_Mask     at 1*Word range 4  .. 7;
      Inst_Address     at 1*Word range 8  .. 31;
  end record;
```
29

```
for Program_Status_Word'Size use 8*System.Storage_Unit;
for Program_Status_Word'Alignment use 8;
```
30

{*AI12-0452-1*} The record_representation_clause defines the record layout. The Size clause guarantees that (at least) eight storage elements are used for objects of the type. The Alignment clause guarantees that aliased, imported, or exported objects of the type will have addresses divisible by eight. 31/5

Wording Changes from Ada 83

The alignment_clause has been renamed to mod_clause and moved to Annex J, "Obsolescent Features". 32.a

We have clarified that implementation-defined component names have to be in the form of an attribute_reference of a component or of the first subtype itself; surely Ada 83 did not intend to allow arbitrary identifiers. 32.b

32.c The RM83-13.4(7) wording incorrectly allows components in nonvariant records to overlap. We have corrected that oversight.

Incompatibilities With Ada 95

32.d/2 {*AI95-00133-01*} **Amendment Correction:** The meaning of a record_representation_clause for the nondefault bit order is now clearly defined. Thus, such clauses can be portably written. In order to do that though, the equivalence of bit 1 in word 1 to bit 9 in word 0 (for a machine with Storage_Unit = 8) had to be dropped for the nondefault bit order. Any record_representation_clauses which depends on that equivalence will break (although such code would imply a noncontiguous representation for a component, and it seems unlikely that compilers were supporting that anyway).

Extensions to Ada 95

32.e/2 {*AI95-00436-01*} **Amendment Correction:** The undocumented (and likely unintentional) incompatibility with Ada 83 caused by not allowing record_representation_clauses on limited record types is removed.

Extensions to Ada 2012

32.f/5 {*AI12-0213-1*} The local_name following **end record** is new.

13.5.2 Storage Place Attributes

Static Semantics

1 For a component C of a composite, non-array object R, the *storage place attributes* are defined:

1.a **Ramification:** The storage place attributes are not (individually) specifiable, but the user may control their values by giving a record_representation_clause.

2/2 R.C'Position

{*AI95-00133-01*} If the nondefault bit ordering applies to the composite type, and if a component_clause specifies the placement of C, denotes the value given for the position of the component_clause; otherwise, denotes the same value as R.C'Address – R'Address. The value of this attribute is of the type *universal_integer*.

2.a/2 **Ramification:** {*AI95-00133-01*} Thus, for the default bit order, R.C'Position is the offset of C in storage elements from the beginning of the object, where the first storage element of an object is numbered zero. R'Address + R.C'Position = R.C'Address. For record extensions, the offset is not measured from the beginning of the extension part, but from the beginning of the whole object, as usual.

2.b In “R.C'Address – R'Address”, the "–" operator is the one in System.Storage_Elements that takes two Addresses and returns a Storage_Offset.

3/2 R.C'First_Bit

{*AI95-00133-01*} If the nondefault bit ordering applies to the composite type, and if a component_clause specifies the placement of C, denotes the value given for the first_bit of the component_clause; otherwise, denotes the offset, from the start of the first of the storage elements occupied by C, of the first bit occupied by C. This offset is measured in bits. The first bit of a storage element is numbered zero. The value of this attribute is of the type *universal_integer*.

4/2 R.C'Last_Bit

{*AI95-00133-01*} If the nondefault bit ordering applies to the composite type, and if a component_clause specifies the placement of C, denotes the value given for the last_bit of the component_clause; otherwise, denotes the offset, from the start of the first of the storage elements occupied by C, of the last bit occupied by C. This offset is measured in bits. The value of this attribute is of the type *universal_integer*.

4.a/2 **Ramification:** {*AI95-00114-01*} The ordering of bits in a storage element is defined in 13.5.3, “Bit Ordering”.

4.b R.C'Size = R.C'Last_Bit – R.C'First_Bit + 1. (Unless the implementation chooses an indirection representation.)

4.c If a component_clause applies to a component, then that component will be at the same relative storage place in all objects of the type. Otherwise, there is no such requirement.

Implementation Advice

If a component is represented using some form of pointer (such as an offset) to the actual data of the component, and this data is contiguous with the rest of the object, then the storage place attributes should reflect the place of the actual data, not the pointer. If a component is allocated discontiguously from the rest of the object, then a warning should be generated upon reference to one of its storage place attributes. 5

Reason: For discontiguous components, these attributes make no sense. For example, an implementation might allocate dynamic-sized components on the heap. For another example, an implementation might allocate the discriminants separately from the other components, so that multiple objects of the same subtype can share discriminants. Such representations cannot happen if there is a component_clause for that component. 5.a

Implementation Advice: If a component is represented using a pointer to the actual data of the component which is contiguous with the rest of the object, then the storage place attributes should reflect the place of the actual data. If a component is allocated discontiguously from the rest of the object, then a warning should be generated upon reference to one of its storage place attributes. 5.b/2

Incompatibilities With Ada 95

{*AI95-00133-01*} **Amendment Correction:** The meaning of the storage place attributes for the nondefault bit order is now clearly defined, and can be different than that given by strictly following the Ada 95 wording. Any code which depends on the original Ada 95 values for a type using the nondefault bit order where they are different will break. 5.c/2

13.5.3 Bit Ordering

[The Bit_Order attribute specifies the interpretation of the storage place attributes.] 1

Reason: The intention is to provide uniformity in the interpretation of storage places across implementations on a particular machine by allowing the user to specify the Bit_Order. It is not intended to fully support data interoperability across different machines, although it can be used for that purpose in some situations. 1.a

{*AI95-00114-01*} We can't require all implementations on a given machine to use the same bit ordering by default; if the user cares, a Bit_Order attribute_definition_clause can be used to force all implementations to use the same bit ordering. 1.b/2

Static Semantics

A bit ordering is a method of interpreting the meaning of the storage place attributes. High_Order_First [(known in the vernacular as “big endian”)] means that the first bit of a storage element (bit 0) is the most significant bit (interpreting the sequence of bits that represent a component as an unsigned integer value). Low_Order_First [(known in the vernacular as “little endian”)] means the opposite: the first bit is the least significant. 2

{*AI12-0373-1*} For every specific record subtype S, the following representation attribute is defined: 3/5

S'Bit_Order 4

Denotes the bit ordering for the type of S. The value of this attribute is of type System.Bit_Order. Bit_Order may be specified for specific record types via an attribute_definition_clause; the expression of such a clause shall be static.

Aspect Description for Bit_Order: Order of bit numbering in a record_representation_clause. 4.a/3

If Word_Size = Storage_Unit, the default bit ordering is implementation defined. If Word_Size > Storage_Unit, the default bit ordering is the same as the ordering of storage elements in a word, when interpreted as an integer. 5

Implementation defined: If Word_Size = Storage_Unit, the default bit ordering. 5.a

Ramification: Consider machines whose Word_Size = 32, and whose Storage_Unit = 8. Assume the default bit ordering applies. On a machine with big-endian addresses, the most significant storage element of an integer is at the address of the integer. Therefore, bit zero of a storage element is the most significant bit. On a machine with little-endian addresses, the least significant storage element of an integer is at the address of the integer. Therefore, bit zero of a storage element is the least significant bit. 5.b

6 The storage place attributes of a component of a type are interpreted according to the bit ordering of the type.

6.a **Ramification:** This implies that the interpretation of the position, first_bit, and last_bit of a component_clause of a record_representation_clause obey the bit ordering given in a representation item.

Implementation Advice

7 The recommended level of support for the nondefault bit ordering is:

8/2 - {*AI95-00133-01*} The implementation should support the nondefault bit ordering in addition to the default bit ordering.

8.a/2 **Ramification:** {*AI95-00133-01*} The implementation should support both bit orderings. Implementations are required to support storage positions that cross storage element boundaries when Word_Size > Storage_Unit but the definition of the storage place attributes for the nondefault bit order ensures that such storage positions will not be split into two or three pieces. Thus, there is no significant implementation burden to supporting the nondefault bit order, given that the set of machine scalars is implementation-defined.

8.b/2 **Implementation Advice:** The recommended level of support for the nondefault bit ordering should be followed.

9/2 NOTE {*AI95-00133-01*} Bit_Order clauses make it possible to write record_representation_clauses that can be ported between machines having different bit ordering. They do not guarantee transparent exchange of data between such machines.

Extensions to Ada 83

9.a The Bit_Order attribute is new to Ada 95.

Wording Changes from Ada 95

9.b/2 {*AI95-00133-01*} We now suggest that all implementations support the nondefault bit order.

13.6 Change of Representation

1/5 {*AI05-0229-1*} {*AI12-0445-1*} [A type_conversion (see 4.6) can be used to convert between two different representations of the same array or record. To convert an array from one representation to another, two array types with matching component subtypes and convertible index types are required. If one type has Pack specified and the other does not, then explicit conversion can be used to pack or unpack an array.

2/5 {*AI12-0425-1*} {*AI12-0445-1*} To convert an untagged record from one representation to another, two record types with a common ancestor type are required. Distinct representations can then be specified for the record types, and explicit conversion between the types can be used to effect a change in representation.]

2.a/5 **Ramification:** {*AI12-0425-1*} The language does not allow implicit copying of by-reference types, so it also does not allow different representations of related by-reference types. Similarly, language rules prevent related tagged types from having different representations of the parent part. Therefore, this technique cannot be used for tagged or by-reference types.

Examples

3 *Example of change of representation:*

4
```
-- Packed_Descriptor and Descriptor are two different types
-- with identical characteristics, apart from their
-- representation
```

5
```
type Descriptor is
    record
       -- components of a descriptor
    end record;
```

6
```
type Packed_Descriptor is new Descriptor;
```

```
for Packed_Descriptor use                                                    7
    record
      -- component clauses for some or for all components
    end record;
-- Change of representation can now be accomplished by explicit type conversions:   8
D : Descriptor;                                                              9
P : Packed_Descriptor;
P := Packed_Descriptor(D);   -- pack D                                       10
D := Descriptor(P);          -- unpack P
```

13.7 The Package System

[For each implementation there is a library package called System which includes the definitions of certain configuration-dependent characteristics.] 1

Static Semantics

The following language-defined library package exists: 2

Implementation defined: The contents of the visible part of package System. 2.a/2

```
{AI95-00362-01} {AI12-0414-1} package System                                 3/5
   with Pure is

   type Name is implementation-defined-enumeration-type;                     4
   System_Name : constant Name := implementation-defined;

   -- System-Dependent Named Numbers:                                        5

   Min_Int               : constant := root_integer'First;                   6
   Max_Int               : constant := root_integer'Last;

   Max_Binary_Modulus    : constant := implementation-defined;               7
   Max_Nonbinary_Modulus : constant := implementation-defined;

   Max_Base_Digits       : constant := root_real'Digits;                     8
   Max_Digits            : constant := implementation-defined;

   Max_Mantissa          : constant := implementation-defined;               9
   Fine_Delta            : constant := implementation-defined;

   Tick                  : constant := implementation-defined;              10

   -- Storage-related Declarations:                                         11

   type Address is implementation-defined;                                  12

end System;
```

19 Name is an enumeration subtype. Values of type Name are the names of alternative machine configurations handled by the implementation. System_Name represents the current machine configuration.

20 The named numbers Fine_Delta and Tick are of the type *universal_real*; the others are of the type *universal_integer*.

21 The meanings of the named numbers are:

22 [Min_Int The smallest (most negative) value allowed for the expressions of a signed_integer_type_definition.

23 Max_Int The largest (most positive) value allowed for the expressions of a signed_integer_type_definition.

24 Max_Binary_Modulus
A power of two such that it, and all lesser positive powers of two, are allowed as the modulus of a modular_type_definition.

25 Max_Nonbinary_Modulus
A value such that it, and all lesser positive integers, are allowed as the modulus of a modular_type_definition.

25.a **Ramification:** There is no requirement that Max_Nonbinary_Modulus be less than or equal to Max_Binary_Modulus, although that's what makes most sense. On a typical 32-bit machine, for example, Max_Binary_Modulus will be 2**32 and Max_Nonbinary_Modulus will be 2**31, because supporting nonbinary moduli in above 2**31 causes implementation difficulties.

26 Max_Base_Digits
The largest value allowed for the requested decimal precision in a floating_point_definition.

27 Max_Digits
The largest value allowed for the requested decimal precision in a floating_point_definition that has no real_range_specification. Max_Digits is less than or equal to Max_Base_Digits.

28 Max_Mantissa
The largest possible number of binary digits in the mantissa of machine numbers of a user-defined ordinary fixed point type. (The mantissa is defined in Annex G.)

29 Fine_Delta
The smallest delta allowed in an ordinary_fixed_point_definition that has the real_range_specification **range** –1.0 .. 1.0.]

30 Tick A period in seconds approximating the real time interval during which the value of Calendar.Clock remains constant.

30.a **Ramification:** There is no required relationship between System.Tick and Duration'Small, other than the one described here.

30.b The inaccuracy of the delay_statement has no relation to Tick. In particular, it is possible that the clock used for the delay_statement is less accurate than Calendar.Clock.

We considered making Tick a run-time-determined quantity, to allow for easier configurability. However, this would not be upward compatible, and the desired configurability can be achieved using functionality defined in Annex D, “Real-Time Systems”. 30.c

Storage_Unit 31
The number of bits per storage element.

Word_Size 32
The number of bits per word.

Memory_Size 33
An implementation-defined value [that is intended to reflect the memory size of the configuration in storage elements.]

Discussion: It is unspecified whether this refers to the size of the address space, the amount of physical memory on the machine, or perhaps some other interpretation of “memory size”. In any case, the value has to be given by a static expression, even though the amount of memory on many modern machines is a dynamic quantity in several ways. Thus, Memory_Size is not very useful. 33.a

{*AI95-00161-01*} Address is a definite, nonlimited type with preelaborable initialization (see 10.2.1). Address represents machine addresses capable of addressing individual storage elements. Null_Address is an address that is distinct from the address of any object or program unit. 34/2

Ramification: The implementation has to ensure that there is at least one address that nothing will be allocated to; Null_Address will be one such address. 34.a

Ramification: Address is the type of the result of the attribute Address. 34.b

Reason: Address is required to be nonlimited and definite because it is important to be able to assign addresses, and to declare uninitialized address variables. 34.c

Ramification: {*AI95-00161-01*} {*AI12-0417-1*} If System.Address is defined as a private type (as suggested below), it might be necessary to add the Preelaborable_Initialization aspect to the declaration of Address in order that it have preelaborable initialization as required. 34.d/5

{*AI95-00221-01*} Default_Bit_Order shall be a static constant. See 13.5.3 for an explanation of Bit_Order and Default_Bit_Order. 35/2

Implementation Permissions

{*AI95-00362-01*} An implementation may add additional implementation-defined declarations to package System and its children. [However, it is usually better for the implementation to provide additional functionality via implementation-defined children of System.] 36/2

Ramification: The declarations in package System and its children can be implicit. For example, since Address is not limited, the predefined "=" and "/=" operations are probably sufficient. However, the implementation is not *required* to use the predefined "=". 36.a

Implementation Advice

Address should be a private type. 37

Reason: This promotes uniformity by avoiding having implementation-defined predefined operations for the type. We don't require it, because implementations may want to stick with what they have. 37.a

Implementation Advice: Type System.Address should be a private type. 37.a.1/2

Implementation Note: It is not necessary for Address to be able to point at individual bits within a storage element. Nor is it necessary for it to be able to point at machine registers. It is intended as a memory address that matches the hardware's notion of an address. 37.b

The representation of the **null** value of a general access type should be the same as that of Null_Address; instantiations of Unchecked_Conversion should work accordingly. If the implementation supports interfaces to other languages, the representation of the **null** value of a general access type should be the same as in those other languages, if appropriate. 37.c

Note that the children of the Interfaces package will generally provide foreign-language-specific null values where appropriate. See UI-0065 regarding Null_Address. 37.d

NOTE There are also some language-defined child packages of System defined elsewhere. 38

Extensions to Ada 83

38.a.1/1 The declarations Max_Binary_Modulus, Max_Nonbinary_Modulus, Max_Base_Digits, Null_Address, Word_Size, Bit_Order, Default_Bit_Order, Any_Priority, Interrupt_Priority, and Default_Priority are added to System in Ada 95. The presence of ordering operators for type Address is also guaranteed (the existence of these depends on the definition of Address in an Ada 83 implementation). We do not list these as incompatibilities, as the contents of System can vary between implementations anyway; thus a program that depends on the contents of System (by using **use** `System;` for example) is already at risk of being incompatible when moved between Ada implementations.

Wording Changes from Ada 83

38.a Much of the content of System is standardized, to provide more uniformity across implementations. Implementations can still add their own declarations to System, but are encouraged to do so via children of System.

38.b Some of the named numbers are defined more explicitly in terms of the standard numeric types.

38.c The pragmas System_Name, Storage_Unit, and Memory_Size are no longer defined by the language. However, the corresponding declarations in package System still exist. Existing implementations may continue to support the three pragmas as implementation-defined pragmas, if they so desire.

38.d Priority semantics, including subtype Priority, have been moved to the Real Time Annex.

Extensions to Ada 95

38.e/2 {*AI95-00161-01*} **Amendment Correction:** Type Address is defined to have preelaborable initialization, so that it can be used without restriction in preelaborated units. (If Address is defined to be a private type, as suggested by the Implementation Advice, in Ada 95 it cannot be used in some contexts in a preelaborated units. This is an unnecessary portability issue.)

38.f/2 {*AI95-00221-01*} **Amendment Correction:** Default_Bit_Order is now a static constant.

38.g/2 {*AI95-00362-01*} Package System is now Pure, so it can be portably used in more places. (Ada 95 allowed it to be Pure, but did not require that.)

13.7.1 The Package System.Storage_Elements

Static Semantics

1 The following language-defined library package exists:

2/5
```
{AI95-00362-01} {AI12-0399-1} package System.Storage_Elements
   with Pure is

3     type Storage_Offset is range implementation-defined;

4     subtype Storage_Count is Storage_Offset range 0..Storage_Offset'Last;

5     type Storage_Element is mod implementation-defined;
      for Storage_Element'Size use Storage_Unit;
      type Storage_Array is array
        (Storage_Offset range <>) of aliased Storage_Element;
      for Storage_Array'Component_Size use Storage_Unit;

6     -- Address Arithmetic:

7/3   {AI05-0229-1}    function "+"(Left : Address; Right : Storage_Offset) return
      Address
            with Convention => Intrinsic;
      function "+"(Left : Storage_Offset; Right : Address) return Address
         with Convention => Intrinsic;
      function "-"(Left : Address; Right : Storage_Offset) return Address
         with Convention => Intrinsic;
      function "-"(Left, Right : Address) return Storage_Offset
         with Convention => Intrinsic;

8/3   {AI05-0229-1}    function "mod"(Left : Address; Right : Storage_Offset)
            return Storage_Offset
               with Convention => Intrinsic;

9     -- Conversion to/from integers:
```

```
{AI05-0229-1}    type Integer_Address is implementation-defined;
   function To_Address(Value : Integer_Address) return Address
      with Convention => Intrinsic;
   function To_Integer(Value : Address) return Integer_Address
      with Convention => Intrinsic;
{AI05-0229-1} end System.Storage_Elements;
```

10/3

11/3

Reason: {*AI05-0229-1*} The Convention aspects imply that the attribute Access is not allowed for those operations. 11.a/3

The **mod** function is needed so that the definition of Alignment makes sense. 11.b

Implementation defined: The range of Storage_Elements.Storage_Offset, the modulus of Storage_Elements.-Storage_Element, and the declaration of Storage_Elements.Integer_Address. 11.c/2

Storage_Element represents a storage element. Storage_Offset represents an offset in storage elements. Storage_Count represents a number of storage elements. Storage_Array represents a contiguous sequence of storage elements. 12

Reason: The index subtype of Storage_Array is Storage_Offset because we wish to allow maximum flexibility. Most Storage_Arrays will probably have a lower bound of 0 or 1, but other lower bounds, including negative ones, make sense in some situations. 12.a

This paragraph was deleted.{*AI95-00114-01*} 12.b/2

Integer_Address is a [(signed or modular)] integer subtype. To_Address and To_Integer convert back and forth between this type and Address. 13

Implementation Requirements

Storage_Offset'Last shall be greater than or equal to Integer'Last or the largest possible storage offset, whichever is smaller. Storage_Offset'First shall be <= (–Storage_Offset'Last). 14

Paragraph 15 was deleted.

Implementation Advice

Operations in System and its children should reflect the target environment semantics as closely as is reasonable. For example, on most machines, it makes sense for address arithmetic to “wrap around”. Operations that do not make sense should raise Program_Error. 16

Implementation Advice: Operations in System and its children should reflect the target environment; operations that do not make sense should raise Program_Error. 16.a.1/2

Discussion: For example, on a segmented architecture, X < Y might raise Program_Error if X and Y do not point at the same segment (assuming segments are unordered). Similarly, on a segmented architecture, the conversions between Integer_Address and Address might not make sense for some values, and so might raise Program_Error. 16.a

Reason: We considered making Storage_Element a private type. However, it is better to declare it as a modular type in the visible part, since code that uses it is already low level, and might as well have access to the underlying representation. We also considered allowing Storage_Element to be any integer type, signed integer or modular, but it is better to have uniformity across implementations in this regard, and viewing storage elements as unsigned seemed to make the most sense. 16.b

Implementation Note: To_Address is intended for use in Address clauses. Implementations should overload To_Address if appropriate. For example, on a segmented architecture, it might make sense to have a record type representing a segment/offset pair, and have a To_Address conversion that converts from that record type to type Address. 16.c

Extensions to Ada 95

{*AI95-00362-01*} Package System.Storage_Elements is now Pure, so it can be portably used in more places. (Ada 95 allowed it to be Pure, but did not require that.) 16.d/2

13.7.2 The Package System.Address_To_Access_Conversions

Static Semantics

1 The following language-defined generic library package exists:

2/5
```
{AI12-0241-1} {AI12-0302-1} generic
   type Object(<>) is limited private;
package System.Address_To_Access_Conversions
   with Preelaborate, Nonblocking, Global => in out synchronized is
```

3/3
```
{AI05-0229-1}    type Object_Pointer is access all Object;
   function To_Pointer(Value : Address) return Object_Pointer
      with Convention => Intrinsic;
   function To_Address(Value : Object_Pointer) return Address
      with Convention => Intrinsic;
```

4/3
```
{AI05-0229-1} end System.Address_To_Access_Conversions;
```

5/2 {*AI95-00230-01*} The To_Pointer and To_Address subprograms convert back and forth between values of types Object_Pointer and Address. To_Pointer(X'Address) is equal to X'Unchecked_Access for any X that allows Unchecked_Access. To_Pointer(Null_Address) returns **null**. For other addresses, the behavior is unspecified. To_Address(**null**) returns Null_Address. To_Address(Y), where Y /= **null**, returns Y.**all**'Address.

5.a/3 **Discussion:** {*AI95-00114-01*} {*AI05-0005-1*} The programmer should ensure that the address passed to To_Pointer is either Null_Address, or the address of an object of type Object. (If Object is not a by-reference type, the object ought to be aliased; recall that the Address attribute is not required to provide a useful result for other objects.) Otherwise, the behavior of the program is unspecified; it might raise an exception or crash, for example.

5.b **Reason:** Unspecified is almost the same thing as erroneous; they both allow arbitrarily bad behavior. We don't say erroneous here, because the implementation might allow the address passed to To_Pointer to point at some memory that just happens to “look like” an object of type Object. That's not necessarily an error; it's just not portable. However, if the actual type passed to Object is (for example) an array type, the programmer would need to be aware of any dope that the implementation expects to exist, when passing an address that did not come from the Address attribute of an object of type Object.

5.c One might wonder why To_Pointer and To_Address are any better than unchecked conversions. The answer is that Address does not necessarily have the same representation as an access type. For example, an access value might point at the bounds of an array when an address would point at the first element. Or an access value might be an offset in words from someplace, whereas an address might be an offset in bytes from the beginning of memory.

Implementation Permissions

6 An implementation may place restrictions on instantiations of Address_To_Access_Conversions.

6.a **Ramification:** For example, if the hardware requires aligned loads and stores, then dereferencing an access value that is not properly aligned might raise an exception.

6.b For another example, if the implementation has chosen to use negative component offsets (from an access value), it might not be possible to preserve the semantics, since negative offsets from the Address are not allowed. (The Address attribute always points at “the first of the storage elements...”.) Note that while the implementation knows how to convert an access value into an address, it might not be able to do the reverse. To avoid generic contract model violations, the restriction might have to be detected at run time in some cases.

13.8 Machine Code Insertions

1 [A machine code insertion can be achieved by a call to a subprogram whose sequence_of_statements contains code_statements.]

Syntax

2 code_statement ::= qualified_expression;

A code_statement is only allowed in the handled_sequence_of_statements of a subprogram_body. If a subprogram_body contains any code_statements, then within this subprogram_body the only allowed form of statement is a code_statement (labeled or not), the only allowed declarative_items are use_clauses, and no exception_handler is allowed (comments and pragmas are allowed as usual). 3

Name Resolution Rules

The qualified_expression is expected to be of any type. 4

Legality Rules

The qualified_expression shall be of a type declared in package System.Machine_Code. 5

Ramification: This includes types declared in children of System.Machine_Code. 5.a

A code_statement shall appear only within the scope of a with_clause that mentions package System.Machine_Code. 6

Ramification: Note that this is not a note; without this rule, it would be possible to write machine code in compilation units which depend on System.Machine_Code only indirectly. 6.a

Static Semantics

The contents of the library package System.Machine_Code (if provided) are implementation defined. The meaning of code_statements is implementation defined. [Typically, each qualified_expression represents a machine instruction or assembly directive.] 7

Discussion: For example, an instruction might be a record with an Op_Code component and other components for the operands. 7.a

Implementation defined: The contents of the visible part of package System.Machine_Code, and the meaning of code_statements. 7.b

Implementation Permissions

An implementation may place restrictions on code_statements. An implementation is not required to provide package System.Machine_Code. 8

NOTE 1 {*AI12-0440-1*} An implementation can provide implementation-defined pragmas specifying register conventions and calling conventions. 9/5

NOTE 2 {*AI95-00318-02*} Machine code functions are exempt from the rule that a return statement is required. In fact, return statements are forbidden, since only code_statements are allowed. 10/2

Discussion: The idea is that the author of a machine code subprogram knows the calling conventions, and refers to parameters and results accordingly. The implementation should document where to put the result of a machine code function, for example, “Scalar results are returned in register 0”. 10.a

NOTE 3 Intrinsic subprograms (see 6.3.1, “Conformance Rules”) can also be used to achieve machine code insertions. Interface to assembly language can be achieved using the features in Annex B, “Interface to Other Languages”. 11

Examples

Example of a code statement: 12

```
{AI05-0229-1} M : Mask;                                                    13/3
procedure Set_Mask
  with Inline;

procedure Set_Mask is                                                      14
  use System.Machine_Code; -- assume "with System.Machine_Code;" appears somewhere above
begin
  SI_Format'(Code => SSM, B => M'Base_Reg, D => M'Disp);
  -- Base_Reg and Disp are implementation-defined attributes
end Set_Mask;
```

Extensions to Ada 83

14.a Machine code functions are allowed in Ada 95; in Ada 83, only procedures were allowed.

Wording Changes from Ada 83

14.b The syntax for code_statement is changed to say "qualified_expression" instead of "subtype_mark'record_aggregate". Requiring the type of each instruction to be a record type is overspecification.

13.9 Unchecked Type Conversions

1 [An unchecked type conversion can be achieved by a call to an instance of the generic function Unchecked_Conversion.]

Static Semantics

2 The following language-defined generic library function exists:

3/5
```
{AI05-0229-1} {AI12-0241-1} generic
   type Source(<>) is limited private;
   type Target(<>) is limited private;
function Ada.Unchecked_Conversion(S : Source) return Target
   with Pure, Nonblocking, Convention => Intrinsic;
```

3.a/3 **Reason:** {*AI05-0229-1*} The aspect Convention implies that the attribute Access is not allowed for instances of Unchecked_Conversion.

Dynamic Semantics

4 The size of the formal parameter S in an instance of Unchecked_Conversion is that of its subtype. [This is the actual subtype passed to Source, except when the actual is an unconstrained composite subtype, in which case the subtype is constrained by the bounds or discriminants of the value of the actual expression passed to S.]

5 If all of the following are true, the effect of an unchecked conversion is to return the value of an object of the target subtype whose representation is the same as that of the source object S:

6 • S'Size = Target'Size.

6.a **Ramification:** Note that there is no requirement that the Sizes be known at compile time.

7/3 • {*AI05-0078-1*} S'Alignment is a multiple of Target'Alignment or Target'Alignment is zero.

8 • The target subtype is not an unconstrained composite subtype.

9 • S and the target subtype both have a contiguous representation.

10 • The representation of S is a representation of an object of the target subtype.

11/2 {*AI95-00426-01*} Otherwise, if the result type is scalar, the result of the function is implementation defined, and can have an invalid representation (see 13.9.1). If the result type is nonscalar, the effect is implementation defined; in particular, the result can be abnormal (see 13.9.1).

11.a.1/2 **Implementation defined:** The result of unchecked conversion for instances with scalar result types whose result is not defined by the language.

11.a/2 **Implementation defined:** The effect of unchecked conversion for instances with nonscalar result types whose effect is not defined by the language.

11.a.1/2 **Reason:** {*AI95-00426-01*} Note the difference between these sentences; the first only says that the bits returned are implementation defined, while the latter allows any effect. The difference is because scalar objects should never be abnormal unless their assignment was disrupted or if they are a subcomponent of an abnormal composite object. Neither exception applies to instances of Unchecked_Conversion.

11.a.2/2 **Ramification:** {*AI95-00426-01*} Whenever unchecked conversions are used, it is the programmer's responsibility to ensure that these conversions maintain the properties that are guaranteed by the language for objects of the target type. For nonscalar types, this requires the user to understand the underlying run-time model of the implementation. The

execution of a program that violates these properties by means of unchecked conversions returning a nonscalar type is erroneous. Properties of scalar types can be checked by using the Valid attribute (see 13.9.2); programs can avoid violating properties of the type (and erroneous execution) by careful use of this attribute.

An instance of Unchecked_Conversion can be applied to an object of a private type, assuming the implementation allows it. 11.b

Implementation Permissions

An implementation may return the result of an unchecked conversion by reference, if the Source type is not a by-copy type. [In this case, the result of the unchecked conversion represents simply a different (read-only) view of the operand of the conversion.] 12

Ramification: In other words, the result object of a call on an instance of Unchecked_Conversion can occupy the same storage as the formal parameter S. 12.a

An implementation may place restrictions on Unchecked_Conversion. 13

Ramification: For example, an instantiation of Unchecked_Conversion for types for which unchecked conversion doesn't make sense may be disallowed. 13.a

Implementation Advice

{*AI95-00051-02*} Since the Size of an array object generally does not include its bounds, the bounds should not be part of the converted data. 14/2

Implementation Advice: Since the Size of an array object generally does not include its bounds, the bounds should not be part of the converted data in an instance of Unchecked_Conversion. 14.a.1/2

Ramification: On the other hand, we have no advice to offer about discriminants and tag fields. 14.a

The implementation should not generate unnecessary runtime checks to ensure that the representation of S is a representation of the target type. It should take advantage of the permission to return by reference when possible. Restrictions on unchecked conversions should be avoided unless required by the target environment. 15

Implementation Advice: There should not be unnecessary runtime checks on the result of an Unchecked_Conversion; the result should be returned by reference when possible. Restrictions on Unchecked_Conversions should be avoided. 15.a.1/2

Implementation Note: As an example of an unnecessary runtime check, consider a record type with gaps between components. The compiler might assume that such gaps are always zero bits. If a value is produced that does not obey that assumption, then the program might misbehave. The implementation should not generate extra code to check for zero bits (except, perhaps, in a special error-checking mode). 15.a

The recommended level of support for unchecked conversions is: 16

- {*AI05-0299-1*} Unchecked conversions should be supported and should be reversible in the cases where this subclause defines the result. To enable meaningful use of unchecked conversion, a contiguous representation should be used for elementary subtypes, for statically constrained array subtypes whose component subtype is one of the subtypes described in this paragraph, and for record subtypes without discriminants whose component subtypes are described in this paragraph. 17/3

Implementation Advice: The recommended level of support for Unchecked_Conversion should be followed. 17.a/2

Wording Changes from Ada 95

{*AI95-00051-02*} The implementation advice about the size of array objects was moved to 13.3 so that all of the advice about Size is in one place. 17.b/2

{*AI95-00426-01*} Clarified that the result of Unchecked_Conversion for scalar types can be invalid, but not abnormal. 17.c/2

Wording Changes from Ada 2005

{*AI05-0078-1*} **Correction:** Relaxed the alignment requirement slightly, giving a defined result in more cases. 17.d/3

13.9.1 Data Validity

1 Certain actions that can potentially lead to erroneous execution are not directly erroneous, but instead can cause objects to become *abnormal*. Subsequent uses of abnormal objects can be erroneous.

2 A scalar object can have an *invalid representation*, which means that the object's representation does not represent any value of the object's subtype. The primary cause of invalid representations is uninitialized variables.

3 Abnormal objects and invalid representations are explained in this subclause.

Dynamic Semantics

4 When an object is first created, and any explicit or default initializations have been performed, the object and all of its parts are in the *normal* state. Subsequent operations generally leave them normal. However, an object or part of an object can become *abnormal* in the following ways:

5 • An assignment to the object is disrupted due to an abort (see 9.8) or due to the failure of a language-defined check (see 11.6).

6/2 • {*AI95-00426-01*} The object is not scalar, and is passed to an **in out** or **out** parameter of an imported procedure, the Read procedure of an instance of Sequential_IO, Direct_IO, or Storage_IO, or the stream attribute T'Read, if after return from the procedure the representation of the parameter does not represent a value of the parameter's subtype.

6.1/2 • {*AI95-00426-01*} The object is the return object of a function call of a nonscalar type, and the function is an imported function, an instance of Unchecked_Conversion, or the stream attribute T'Input, if after return from the function the representation of the return object does not represent a value of the function's subtype.

6.a/2 **Discussion:** We explicitly list the routines involved in order to avoid future arguments. All possibilities are listed.

6.b/2 We did not include Stream_IO.Read in the list above. A Stream_Element should include all possible bit patterns, and thus it cannot be invalid. Therefore, the parameter will always represent a value of its subtype. By omitting this routine, we make it possible to write arbitrary I/O operations without any possibility of abnormal objects.

6.2/2 {*AI95-00426-01*} [For an imported object, it is the programmer's responsibility to ensure that the object remains in a normal state.]

6.c/2 **Proof:** This follows (and echos) the standard rule of interfacing; the programmer must ensure that Ada semantics are followed (see B.1).

7 Whether or not an object actually becomes abnormal in these cases is not specified. An abnormal object becomes normal again upon successful completion of an assignment to the object as a whole.

Erroneous Execution

8 It is erroneous to evaluate a primary that is a name denoting an abnormal object, or to evaluate a prefix that denotes an abnormal object.

8.a/2 *This paragraph was deleted.*{*AI95-00114-01*}

8.b **Ramification:** The **in out** or **out** parameter case does not apply to scalars; bad scalars are merely invalid representations, rather than abnormal, in this case.

8.c/2 **Reason:** {*AI95-00114-01*} The reason we allow access objects, and objects containing subcomponents of an access type, to become abnormal is because the correctness of an access value cannot necessarily be determined merely by looking at the bits of the object. The reason we allow scalar objects to become abnormal is that we wish to allow the compiler to optimize assuming that the value of a scalar object belongs to the object's subtype, if the compiler can prove that the object is initialized with a value that belongs to the subtype. The reason we allow composite objects to become abnormal is that such object might be represented with implicit levels of indirection; if those are corrupted, then even assigning into a component of the object, or simply asking for its Address, might have an unpredictable effect. The same is true if the discriminants have been destroyed.

Bounded (Run-Time) Errors

If the representation of a scalar object does not represent a value of the object's subtype (perhaps because the object was not initialized), the object is said to have an *invalid representation*. It is a bounded error to evaluate the value of such an object. If the error is detected, either Constraint_Error or Program_Error is raised. Otherwise, execution continues using the invalid representation. The rules of the language outside this subclause assume that all objects have valid representations. The semantics of operations on invalid representations are as follows: 9

Discussion: The AARM is more explicit about what happens when the value of the case expression is an invalid representation. 9.a

Ramification: {*AI95-00426-01*} This includes the result object of functions, including the result of Unchecked_Conversion, T'Input, and imported functions. 9.b/2

- If the representation of the object represents a value of the object's type, the value of the type is used. 10
- If the representation of the object does not represent a value of the object's type, the semantics of operations on such representations is implementation-defined, but does not by itself lead to erroneous or unpredictable execution, or to other objects becoming abnormal. 11

Implementation Note: {*AI95-00426-01*} This means that the implementation must take care not to use an invalid representation in a way that might cause erroneous execution. For instance, the exception mandated for case_statements must be raised. Array indexing must not cause memory outside of the array to be written (and usually, not read either). These cases and similar cases may require explicit checks by the implementation. 11.a/2

Erroneous Execution

{*AI95-00167-01*} {*AI05-0279-1*} A call to an imported function or an instance of Unchecked_Conversion is erroneous if the result is scalar, the result object has an invalid representation, and the result is used other than as the expression of an assignment_statement or an object_declaration, as the *object*_name of an object_renaming_declaration, or as the prefix of a Valid attribute. If such a result object is used as the source of an assignment, and the assigned value is an invalid representation for the target of the assignment, then any use of the target object prior to a further assignment to the target object, other than as the prefix of a Valid attribute reference, is erroneous. 12/3

Ramification: {*AI95-00167-01*} In a typical implementation, every bit pattern that fits in an object of a signed integer subtype will represent a value of the type, if not of the subtype. However, for an enumeration or floating point type, as well as some modular types, there are typically bit patterns that do not represent any value of the type. In such cases, the implementation ought to define the semantics of operations on the invalid representations in the obvious manner (assuming the bounded error is not detected): a given representation should be equal to itself, a representation that is in between the internal codes of two enumeration literals should behave accordingly when passed to comparison operators and membership tests, etc. We considered *requiring* such sensible behavior, but it resulted in too much arcane verbiage, and since implementations have little incentive to behave irrationally, such verbiage is not important to have. 12.a/2

{*AI95-00167-01*} If a stand-alone scalar object is initialized to a an in-range value, then the implementation can take advantage of the fact that the use of any out-of-range value has to be erroneous. Such an out-of-range value can be produced only by things like unchecked conversion, imported functions, and abnormal values caused by disruption of an assignment due to abort or to failure of a language-defined check. This depends on out-of-range values being checked before assignment (that is, checks are not optimized away unless they are proven redundant). 12.b/2

Consider the following example: 12.c

{*AI95-00167-01*} 12.d/2

```
type My_Int is range 0..99;
function Safe_Convert is new Unchecked_Conversion(My_Int, Integer);
function Unsafe_Convert is new Unchecked_Conversion(My_Int, Positive);
X : Positive := Safe_Convert(0); -- Raises Constraint_Error.
Y : Positive := Unsafe_Convert(0); -- Bounded Error, may be invalid.
B : Boolean  := Y'Valid; -- OK, B = False.
Z : Positive := Y+1; -- Erroneous to use Y.
```

{*AI95-00167-01*} {*AI95-00426-01*} The call to Unsafe_Convert is a bounded error, which might raise Constraint_Error, Program_Error, or return an invalid value. Moreover, if an exception is not raised, most uses of that invalid value (including the use of Y) cause erroneous execution. The call to Safe_Convert is not erroneous. The result object is an object of subtype Integer containing the value 0. The assignment to X is required to do a constraint check; 12.e/2

the fact that the conversion is unchecked does not obviate the need for subsequent checks required by the language rules.

12.e.1/2 {*AI95-00167-01*} {*AI95-00426-01*} The reason for delaying erroneous execution until the object is used is so that the invalid representation can be tested for validity using the Valid attribute (see 13.9.2) without causing execution to become erroneous. Note that this delay does not imply an exception will not be raised; an implementation could treat both conversions in the example in the same way and raise Constraint_Error.

12.e.2/3 {*AI05-0279-1*} The rules are defined in terms of the result object, and thus the name used to reference that object is irrelevant. That is why we don't need any special rules to describe what happens when the function result is renamed.

12.f **Implementation Note:** If an implementation wants to have a “friendly” mode, it might always assign an uninitialized scalar a default initial value that is outside the object's subtype (if there is one), and check for this value on some or all reads of the object, so as to help detect references to uninitialized scalars. Alternatively, an implementation might want to provide an “unsafe” mode where it presumed even uninitialized scalars were always within their subtype.

12.g **Ramification:** The above rules imply that it is a bounded error to apply a predefined operator to an object with a scalar subcomponent having an invalid representation, since this implies reading the value of each subcomponent. Either Program_Error or Constraint_Error is raised, or some result is produced, which if composite, might have a corresponding scalar subcomponent still with an invalid representation.

12.h Note that it is not an error to assign, convert, or pass as a parameter a composite object with an uninitialized scalar subcomponent. In the other hand, it is a (bounded) error to apply a predefined operator such as =, <, and **xor** to a composite operand with an invalid scalar subcomponent.

13/3 {*AI05-0054-2*} The dereference of an access value is erroneous if it does not designate an object of an appropriate type or a subprogram with an appropriate profile, if it designates a nonexistent object, or if it is an access-to-variable value that designates a constant object and it did not originate from an attribute_reference applied to an aliased variable view of a controlled or immutably limited object. [An access value whose dereference is erroneous can exist, for example, because of Unchecked_Deallocation, Unchecked_Access, or Unchecked_Conversion.]

13.a **Ramification:** The above mentioned Unchecked_... features are not the only causes of such access values. For example, interfacing to other languages can also cause the problem.

13.b/3 {*AI05-0054-2*} We permit the use of access-to-variable values that designate constant objects so long as they originate from an aliased variable view of a controlled or immutably limited constant, such as during the initialization of a constant (both via the “current instance” and during a call to Initialize) or during an assignment (during a call to Adjust).

14 NOTE Objects can become abnormal due to other kinds of actions that directly update the object's representation; such actions are generally considered directly erroneous, however.

Wording Changes from Ada 83

14.a In order to reduce the amount of erroneousness, we separate the concept of an undefined value into objects with invalid representation (scalars only) and abnormal objects.

14.b Reading an object with an invalid representation is a bounded error rather than erroneous; reading an abnormal object is still erroneous. In fact, the only safe thing to do to an abnormal object is to assign to the object as a whole.

Wording Changes from Ada 95

14.c/2 {*AI95-00167-01*} The description of erroneous execution for Unchecked_Conversion and imported objects was tightened up so that using the Valid attribute to test such a value is not erroneous.

14.d/2 {*AI95-00426-01*} Clarified the definition of objects that can become abnormal; made sure that all of the possibilities are included.

Wording Changes from Ada 2005

14.e/3 {*AI05-0054-2*} **Correction:** Common programming techniques such as squirreling away an access to a controlled object during initialization and using a self-referencing discriminant (the so-called “Rosen trick”) no longer are immediately erroneous if the object is declared constant, so these techniques can be used portably and safely. Practically, these techniques already worked as compilers did not take much advantage of this rule, so the impact of this change will be slight.

14.f/3 {*AI05-0279-1*} **Correction:** The description of erroneous execution for Unchecked_Conversion and imported objects was adjusted to clarify that renaming such an object is not, by itself, erroneous.

13.9.2 The Valid Attribute

The Valid attribute can be used to check the validity of data produced by unchecked conversion, input, interface to foreign languages, and the like. 1

Static Semantics

For a prefix X that denotes a scalar object [(after any implicit dereference)], the following attribute is defined: 2

X'Valid {*AI05-0153-3*} {*AI12-0071-1*} Yields True if and only if the object denoted by X is normal, has a valid representation, and then, if the preceding conditions hold, the value of X also satisfies the predicates of the nominal subtype of X. The value of this attribute is of the predefined type Boolean. 3/4

Ramification: Having checked that X'Valid is True, it is safe to read the value of X without fear of erroneous execution caused by abnormality, or a bounded error caused by an invalid representation. Such a read will produce a value in the subtype of X. 3.a

NOTE 1 Invalid data can be created in the following cases (not counting erroneous or unpredictable execution): 4

- an uninitialized scalar object, 5
- the result of an unchecked conversion, 6
- input, 7
- interface to another language (including machine code), 8
- aborting an assignment, 9
- disrupting an assignment due to the failure of a language-defined check (see 11.6), and 10
- use of an object whose Address has been specified. 11

NOTE 2 {*AI12-0071-1*} {*AI12-0440-1*} Determining whether X is normal and has a valid representation as part of the evaluation of X'Valid is not considered to include an evaluation of X; hence, it is not an error to check the validity of an object that is invalid or abnormal. Determining whether X satisfies the predicates of its nominal subtype can include an evaluation of X, but only after it has been determined that X has a valid representation. 12/5

{*AI12-0071-1*} If X is volatile, the evaluation of X'Valid is considered a read of X. 13/4

Reason: Since an implementation is not allowed to add, remove, or reorder accesses to volatile objects, we have to define X'Valid as a read so that it is implementable for most subtypes as the value of the object is required. 13.a/4

NOTE 3 {*AI95-00426-01*} {*AI12-0442-1*} The Valid attribute can be used to check the result of calling an instance of Unchecked_Conversion (or any other operation that can return invalid values). However, an exception handler is still useful because implementations are permitted to raise Constraint_Error or Program_Error if they detect the use of an invalid representation (see 13.9.1). 14/5

Ramification: If X is of an enumeration type with a representation clause, then X'Valid checks that the value of X when viewed as an integer is one of the specified internal codes. 14.a

Reason: Valid is defined only for scalar objects because the implementation and description burden would be too high for other types. For example, given a typical run-time model, it is impossible to check the validity of an access value. The same applies to composite types implemented with internal pointers. One can check the validity of a composite object by checking the validity of each of its scalar subcomponents. The user should ensure that any composite types that need to be checked for validity are represented in a way that does not involve implementation-defined components, or gaps between components. Furthermore, such types should not contain access subcomponents. 14.b

This paragraph was deleted.{*AI95-00114-01*} 14.c/2

Extensions to Ada 83

X'Valid is new in Ada 95. 14.d

Wording Changes from Ada 95

{*AI95-00426-01*} Added a note explaining that handlers for Constraint_Error and Program_Error are needed in the general case of testing for validity. (An implementation could document cases where these are not necessary, but there is no language requirement.) 14.e/2

Wording Changes from Ada 2005

14.f/3 {*AI05-0153-3*} The validity check now also includes a check of the predicate aspects (see 3.2.4), if any, of the subtype of the object.

Wording Changes from Ada 2012

14.g/4 {*AI12-0071-1*} **Corrigendum:** Updated wording of the attributes X'Valid to use the new term "satisfies the predicates" (see 3.2.4). Also updated the notes to make sense when evaluating predicates and testing validity of volatile objects.

13.10 Unchecked Access Value Creation

1 [The attribute Unchecked_Access is used to create access values in an unsafe manner — the programmer is responsible for preventing “dangling references”.]

Static Semantics

2 The following attribute is defined for a prefix X that denotes an aliased view of an object:

3 X'Unchecked_Access

All rules and semantics that apply to X'Access (see 3.10.2) apply also to X'Unchecked_Access, except that, for the purposes of accessibility rules and checks, it is as if X were declared immediately within a library package.

3.a/3 **Ramification:** {*AI05-0005-1*} We say “rules and semantics” here so that library-level accessibility applies to the value created by X'Unchecked_Access as well as to the checks needed for the attribute itself. This means that any anonymous access values that inherit the accessibility of this attribute (such as access parameters) also act as if they have library-level accessibility. We don't want the "real" accessibility of the created value re-emerging at a later point – that would create hard-to-understand bugs.

4/5 NOTE 1 {*AI12-0449-1*} This attribute is provided to support the situation where a local object is to be inserted into a global linked data structure, when the programmer knows that it will always be removed from the data structure prior to exiting the object's scope. The Access attribute would be illegal in this case (see 3.10.2).

4.a **Ramification:** The expected type for X'Unchecked_Access is as for X'Access.

4.b If an attribute_reference with Unchecked_Access is used as the actual parameter for an access parameter, an Accessibility_Check can never fail on that access parameter.

5 NOTE 2 There is no Unchecked_Access attribute for subprograms.

5.a/2 **Reason:** {*AI95-00254-01*} Such an attribute would allow unsafe “downward closures”, where an access value designating a more nested subprogram is passed to a less nested subprogram. (Anonymous access-to-subprogram parameters provide safe “downward closures”.) This requires some means of reconstructing the global environment for the more nested subprogram, so that it can do up-level references to objects. The two methods of implementing up-level references are displays and static links. If unsafe downward closures were supported, each access-to-subprogram value would have to carry the static link or display with it. We don't want to require the space and time overhead of requiring the extra information for all access-to-subprogram types, especially as including it would make interfacing to other languages (like C) harder.

5.b If desired, an instance of Unchecked_Conversion can be used to create an access value of a global access-to-subprogram type that designates a local subprogram. The semantics of using such a value are not specified by the language. In particular, it is not specified what happens if such subprograms make up-level references; even if the frame being referenced still exists, the up-level reference might go awry if the representation of a value of a global access-to-subprogram type doesn't include a static link.

13.11 Storage Management

1 [Each access-to-object type has an associated storage pool. The storage allocated by an allocator comes from the pool; instances of Unchecked_Deallocation return storage to the pool. Several access types can share the same pool.]

2/2 {*AI95-00435-01*} [A storage pool is a variable of a type in the class rooted at Root_Storage_Pool, which is an abstract limited controlled type. By default, the implementation chooses a *standard storage pool* for

each access-to-object type. The user may define new pool types, and may override the choice of pool for an access-to-object type by specifying Storage_Pool for the type.]

Ramification: By default, the implementation might choose to have a single global storage pool, which is used (by default) by all access types, which might mean that storage is reclaimed automatically only upon partition completion. Alternatively, it might choose to create a new pool at each accessibility level, which might mean that storage is reclaimed for an access type when leaving the appropriate scope. Other schemes are possible. 2.a

Term entry: storage pool object — object associated with one or more access types from which the storage for objects created by allocators of the access type(s) is obtained 2.b/5
Note: Some storage pools can be partitioned into subpools in order to support finer-grained storage management.

Legality Rules

If Storage_Pool is specified for a given access type, Storage_Size shall not be specified for it. 3

Reason: The Storage_Pool determines the Storage_Size; hence it would not make sense to specify both. Note that this rule is simplified by the fact that the aspects in question cannot be specified for derived types, nor for nonfirst subtypes, so we don't have to worry about whether, say, Storage_Pool on a derived type overrides Storage_Size on the parent type. For the same reason, “specified” means the same thing as “directly specified” here. 3.a

Static Semantics

The following language-defined library package exists: 4

```
{AI12-0235-1} with Ada.Finalization;                                                    5/5
with System.Storage_Elements;
package System.Storage_Pools
    with Pure, Nonblocking => False is

{AI95-00161-01} {AI12-0399-1}     type Root_Storage_Pool is                             6/5
        abstract new Ada.Finalization.Limited_Controlled with private
        with Preelaborable_Initialization;

    procedure Allocate(                                                                 7
      Pool : in out Root_Storage_Pool;
      Storage_Address : out Address;
      Size_In_Storage_Elements : in Storage_Elements.Storage_Count;
      Alignment : in Storage_Elements.Storage_Count) is abstract;

    procedure Deallocate(                                                               8
      Pool : in out Root_Storage_Pool;
      Storage_Address : in Address;
      Size_In_Storage_Elements : in Storage_Elements.Storage_Count;
      Alignment : in Storage_Elements.Storage_Count) is abstract;

    function Storage_Size(Pool : Root_Storage_Pool)                                     9
       return Storage_Elements.Storage_Count is abstract;

private                                                                                 10
   ... -- not specified by the language
end System.Storage_Pools;
```

Reason: The Alignment parameter is provided to Deallocate because some allocation strategies require it. If it is not needed, it can be ignored. 10.a

A *storage pool type* (or *pool type*) is a descendant of Root_Storage_Pool. The *elements* of a storage pool are the objects allocated in the pool by allocators. 11

Discussion: In most cases, an element corresponds to a single memory block allocated by Allocate. However, in some cases the implementation may choose to associate more than one memory block with a given pool element. 11.a

{*8652/0009*} {*AI95-00137-01*} {*AI95-00435-01*} For every access-to-object subtype S, the following representation attributes are defined: 12/2

S'Storage_Pool 13
: Denotes the storage pool of the type of S. The type of this attribute is Root_Storage_-Pool'Class.

14 S'Storage_Size

Yields the result of calling Storage_Size(S'Storage_Pool)[, which is intended to be a measure of the number of storage elements reserved for the pool.] The type of this attribute is *universal_integer*.

14.a **Ramification:** Storage_Size is also defined for task subtypes and objects — see 13.3.

14.b Storage_Size is not a measure of how much un-allocated space is left in the pool. That is, it includes both allocated and unallocated space. Implementations and users may provide a Storage_Available function for their pools, if so desired.

15/5 {*AI12-0319-1*} Storage_Size or Storage_Pool may be specified for a nonderived access-to-object type via an attribute_definition_clause; the name in a Storage_Pool clause shall denote a variable. If the nominal subtype of the name specified for Storage_Pool is nonblocking (see 9.5), then the primitive Allocate, Deallocate, and Storage_Size subprograms of that type shall be nonblocking. Additionally, if the pool is one that supports subpools (see 13.11.4), the primitive Default_Subpool_for_Pool, Allocate_From_Subpool, and Deallocate_Subpool subprograms shall be nonblocking.

15.a/3 **Aspect Description for Storage_Pool:** Pool of memory from which **new** will allocate for a given access type.

15.b/3 **Aspect Description for Storage_Size (access):** Sets memory size for allocations for an access type.

15.c/5 **Reason:** {*AI12-0319-1*} We need to be able to describe in contracts (especially for generic units) whether the operations of a storage pool allow blocking, and we do that with the nonblocking status of the type. We make the check when the pool is specified so we can avoid adding a special check to the declaration of a pool type – we want pool types to follow the same rules as any other type.

16/3 {*AI05-0107-1*} {*AI05-0111-3*} {*AI05-0116-1*} An allocator of a type *T* that does not support subpools allocates storage from *T*'s storage pool. If the storage pool is a user-defined object, then the storage is allocated by calling Allocate as described below. Allocators for types that support subpools are described in 13.11.4.

16.a **Ramification:** If the implementation chooses to represent the designated subtype in multiple pieces, one allocator evaluation might result in more than one call upon Allocate. In any case, allocators for the access type obtain all the required storage for an object of the designated type by calling the specified Allocate procedure.

16.b/3 *This paragraph was deleted.*{*AI05-0107-1*}

16.b.1/1 {*8652/0111*} {*AI95-00103-01*} If *D* (the designated type of *T*) includes subcomponents of other access types, they will be allocated from the storage pools for those types, even if those allocators are executed as part of the allocator of *T* (as part of the initialization of the object). For instance, an access-to-task type *TT* may allocate the data structures used to implement the task value from other storage pools. (In particular, the task stack does not necessarily need to be allocated from the storage pool for *TT*.)

17 If Storage_Pool is not specified for a type defined by an access_to_object_definition, then the implementation chooses a standard storage pool for it in an implementation-defined manner. In this case, the exception Storage_Error is raised by an allocator if there is not enough storage. It is implementation defined whether or not the implementation provides user-accessible names for the standard pool type(s).

17.a/2 *This paragraph was deleted.*

17.a.1/2 **Discussion:** The manner of choosing a storage pool is covered by a Documentation Requirement below, so it is not summarized here.

17.b **Implementation defined:** Whether or not the implementation provides user-accessible names for the standard pool type(s).

17.b.1/5 **To be honest:** {*AI12-0005-1*} **pragma** Default_Storage_Pool (see 13.11.3) can be used to specify a specific pool (or none at all) to be used with access types declared in a particular declaration list, rather than a standard storage pool.

17.b.2/5 {*AI12-0005-1*} Although there is no language-defined user-accessible name for the standard pool type(s), the default use of a standard pool may be indicated using the identifier Standard in the **pragma** Default_Storage_Pool.

17.c/2 **Ramification:** {*AI95-00230-01*} An access-to-object type defined by a derived_type_definition inherits its pool from its parent type, so all access-to-object types in the same derivation class share the same pool. Hence the "defined by an access_to_object_definition" wording above.

17.d There is no requirement that all storage pools be implemented using a contiguous block of memory (although each allocation returns a pointer to a contiguous block of memory).

{*AI12-0319-1*} {*AI12-0424-1*} The type(s) of the standard pool(s), and the primitive Allocate, Deallocate, and Storage_Size subprograms for the standard pool(s) are nonblocking. Concurrent invocations of these subprograms do not conflict with one another (see 9.10) when applied to standard storage pools. 17.1/5

Reason: We need to specify that the type is nonblocking so that an instance of Unchecked_Deallocation is nonblocking if the object type is nonblocking (as the type is used in the contract). Ada 95 did not declare standard allocation/deallocation as potentially blocking, so these things can be used in protected types, and we want that to remain true (with static checking). 17.e/5

{*AI12-0043-1*} {*AI12-0319-1*} If Storage_Size is specified for an access type *T*, an implementation-defined pool *P* is used for the type. The Storage_Size of *P* is at least that requested, and the storage for *P* is reclaimed when the master containing the declaration of the access type is left. If the implementation cannot satisfy the request, Storage_Error is raised at the freezing point of type *T*. The storage pool *P* is used only for allocators returning type *T* or other access types specified to use *T*'Storage_Pool. Storage_Error is raised by an allocator returning such a type if the storage space of *P* is exhausted (additional memory is not allocated). The type of *P*, and the primitive Allocate, Deallocate, and Storage_Size subprograms of *P* are nonblocking. 18/5

{*AI12-0043-1*} If neither Storage_Pool nor Storage_Size are specified, then the meaning of Storage_Size is implementation defined. 18.1/4

Implementation defined: The meaning of Storage_Size when neither the Storage_Size nor the Storage_Pool is specified for an access type. 18.a/2

Ramification: The Storage_Size function and attribute will return the actual size, rather than the requested size. Comments about rounding up, zero, and negative on task Storage_Size apply here, as well. See also AI83-00557, AI83-00558, and AI83-00608. 18.b

The expression in a Storage_Size clause need not be static. 18.c

The reclamation happens after the master is finalized. 18.d

Implementation Note: For a pool allocated on the stack, normal stack cut-back can accomplish the reclamation. For a library-level pool, normal partition termination actions can accomplish the reclamation. 18.e

If Storage_Pool is specified for an access type, then the specified pool is used. 19

The effect of calling Allocate and Deallocate for a standard storage pool directly (rather than implicitly via an allocator or an instance of Unchecked_Deallocation) is unspecified. 20

Ramification: For example, an allocator might put the pool element on a finalization list. If the user directly Deallocates it, instead of calling an instance of Unchecked_Deallocation, then the implementation would probably try to finalize the object upon master completion, which would be bad news. Therefore, the implementation should define such situations as erroneous. 20.a

Erroneous Execution

If Storage_Pool is specified for an access type, then if Allocate can satisfy the request, it should allocate a contiguous block of memory, and return the address of the first storage element in Storage_Address. The block should contain Size_In_Storage_Elements storage elements, and should be aligned according to Alignment. The allocated storage should not be used for any other purpose while the pool element remains in existence. If the request cannot be satisfied, then Allocate should propagate an exception [(such as Storage_Error)]. If Allocate behaves in any other manner, then the program execution is erroneous. 21

Implementation Requirements

{*AI05-0107-1*} {*AI05-0262-1*} The Allocate procedure of a user-defined storage pool object *P* may be called by the implementation only to allocate storage for a type *T* whose pool is *P*, only at the following points: 21.1/3

- During the execution of an allocator of type *T*; 21.2/3

21.a/3 **Ramification:** This includes during the evaluation of the initializing expression such as an aggregate; this is important if the initializing expression is built in place. We need to allow allocation to be deferred until the size of the object is known.

21.3/3 - During the execution of a return statement for a function whose result is built-in-place in the result of an allocator of type *T*;

21.b/3 **Reason:** We need this bullet as well as the preceding one in order that exceptions that propagate from such a call to Allocate can be handled within the return statement. We don't want to require the generation of special handling code in this unusual case, as it would add overhead to most return statements of composite types.

21.4/3 - During the execution of an assignment operation with a target of an allocated object of type *T* with a part that has an unconstrained discriminated subtype with defaults.

21.c/3 **Reason:** We allow Allocate to be called during assignment of objects with mutable parts so that mutable objects can be implemented with reallocation on assignment. (Unfortunately, the term "mutable" is only defined in the AARM, so we have to use the long-winded wording shown here.)

21.d/3 **Discussion:** Of course, explicit calls to Allocate are also allowed and are not bound by any of the rules found here.

21.5/3 {*AI05-0107-1*} {*AI05-0116-1*} {*AI05-0193-1*} {*AI05-0262-1*} {*AI05-0269-1*} For each of the calls of Allocate described above, *P* (equivalent to *T*'Storage_Pool) is passed as the Pool parameter. The Size_In_Storage_Elements parameter indicates the number of storage elements to be allocated, and is no more than *D*'Max_Size_In_Storage_Elements, where *D* is the designated subtype of *T*. The Alignment parameter is a nonzero integral multiple of *D*'Alignment if *D* is a specific type, and otherwise is a nonzero integral multiple of the alignment of the specific type identified by the tag of the object being created; it is unspecified if there is no such value. The Alignment parameter is no more than *D*'Max_Alignment_For_Allocation. The result returned in the Storage_Address parameter is used as the address of the allocated storage, which is a contiguous block of memory of Size_In_Storage_Elements storage elements. [Any exception propagated by Allocate is propagated by the construct that contained the call.]

21.e/3 **Ramification:** Note that the implementation does not turn other exceptions into Storage_Error.

21.f/3 “Nonzero integral multiple” of an alignment includes the alignment value itself, of course. The value is unspecified if the alignment of the specific type is zero.

21.6/5 {*AI05-0107-1*} {*AI12-0445-1*} The number of calls to Allocate that will be used to implement an allocator for any particular type is unspecified. The number of calls to Deallocate that will be used to implement an instance of Unchecked_Deallocation (see 13.11.2) for any particular object is the same as the number of Allocate calls for that object.

21.g/3 **Reason:** This supports objects that are allocated in one or more parts. The second sentence prevents extra or missing calls to Deallocate.

21.h/3 **To be honest:** {*AI05-0005-1*} The number of calls to Deallocate from all sources for an object always will be the same as the number of calls to Allocate from all sources for that object. However, in unusual cases, not all of those Deallocate calls may be made by an instance of Unchecked_Deallocation. Specifically, in the unusual case of assigning to an object of a mutable variant record type such that the variant changes, some of the Deallocate calls may be made by the assignment (as may some of the Allocate calls).

21.i/3 **Ramification:** We do not define the relative order of multiple calls used to deallocate the same object — that is, if the allocator allocated two pieces *x* and *y*, then an instance of Unchecked_Deallocation might deallocate *x* and then *y*, or it might deallocate *y* and then *x*.

21.7/3 {*AI05-0107-1*} The Deallocate procedure of a user-defined storage pool object *P* may be called by the implementation to deallocate storage for a type *T* whose pool is *P* only at the places when an Allocate call is allowed for *P*, during the execution of an instance of Unchecked_Deallocation for *T*, or as part of the finalization of the collection of *T*. For such a call of Deallocate, *P* (equivalent to *T*'Storage_Pool) is passed as the Pool parameter. The value of the Storage_Address parameter for a call to Deallocate is the value returned in the Storage_Address parameter of the corresponding successful call to Allocate. The values of the Size_In_Storage_Elements and Alignment parameters are the same values passed to the

corresponding Allocate call. Any exception propagated by Deallocate is propagated by the construct that contained the call.

Reason: We allow Deallocate to be called anywhere that Allocate is, in order to allow the recovery of storage from failed allocations (that is, those that raise exceptions); from extended return statements that exit via a goto, exit, or locally handled exception; and from objects that are reallocated when they are assigned. In each of these cases, we would have a storage leak if the implementation did not recover the storage (there is no way for the programmer to do it). We do not require such recovery, however, as it could be a serious performance drag on these operations. 21.j/3

Documentation Requirements

{*AI12-0445-1*} An implementation shall document the set of values that a user-defined Allocate procedure has to accept for the Alignment parameter. An implementation shall document how the standard storage pool is chosen, and how storage is allocated by standard storage pools. 22/5

This paragraph was deleted. 22.a/2

Documentation Requirement: The set of values that a user-defined Allocate procedure needs to accept for the Alignment parameter. How the standard storage pool is chosen, and how storage is allocated by standard storage pools. 22.b/2

Implementation Advice

An implementation should document any cases in which it dynamically allocates heap storage for a purpose other than the evaluation of an allocator. 23

Implementation Advice: Any cases in which heap storage is dynamically allocated other than as part of the evaluation of an allocator should be documented. 23.a.1/2

Reason: This is “Implementation Advice” because the term “heap storage” is not formally definable; therefore, it is not testable whether the implementation obeys this advice. 23.a

A default (implementation-provided) storage pool for an access-to-constant type should not have overhead to support deallocation of individual objects. 24

Implementation Advice: A default storage pool for an access-to-constant type should not have overhead to support deallocation of individual objects. 24.a.1/2

Ramification: Unchecked_Deallocation is not defined for such types. If the access-to-constant type is library-level, then no deallocation (other than at partition completion) will ever be necessary, so if the size needed by an allocator of the type is known at link-time, then the allocation should be performed statically. If, in addition, the initial value of the designated object is known at compile time, the object can be allocated to read-only memory. 24.a

Implementation Note: If the Storage_Size for an access type is specified, the storage pool should consist of a contiguous block of memory, possibly allocated on the stack. The pool should contain approximately this number of storage elements. These storage elements should be reserved at the place of the Storage_Size clause, so that allocators cannot raise Storage_Error due to running out of pool space until the appropriate number of storage elements has been used up. This approximate (possibly rounded-up) value should be used as a maximum; the implementation should not increase the size of the pool on the fly. If the Storage_Size for an access type is specified as zero, then the pool should not take up any storage space, and any allocator for the type should raise Storage_Error. 24.b

Ramification: Note that most of this is approximate, and so cannot be (portably) tested. That's why we make it an Implementation Note. There is no particular number of allocations that is guaranteed to succeed, and there is no particular number of allocations that is guaranteed to fail. 24.c

{*AI95-00230-01*} The storage pool used for an allocator of an anonymous access type should be determined as follows: 25/2

- {*AI95-00230-01*} {*AI95-00416-01*} If the allocator is defining a coextension (see 3.10.2) of an object being created by an outer allocator, then the storage pool used for the outer allocator should also be used for the coextension; 25.1/2
- {*AI95-00230-01*} For other access discriminants and access parameters, the storage pool should be created at the point of the allocator, and be reclaimed when the allocated object becomes inaccessible; 25.2/2
- {*AI05-0051-1*} If the allocator defines the result of a function with an access result, the storage pool is determined as though the allocator were in place of the call of the function. If the call is 25.3/3

the operand of a type conversion, the storage pool is that of the target access type of the conversion. If the call is itself defining the result of a function with an access result, this rule is applied recursively;

25.4/5 • {*AI95-00230-01*} {*AI12-0444-1*} Otherwise, a default storage pool should be created at the point where the anonymous access type is elaborated; such a storage pool may have no mechanism for the deallocation of individual objects.

25.a.1/2 **Implementation Advice:** Usually, a storage pool for an access discriminant or access parameter should be created at the point of an allocator, and be reclaimed when the designated object becomes inaccessible. For other anonymous access types, the pool should be created at the point where the type is elaborated and may have no mechanism for the deallocation of individual objects.

25.a/2 **Implementation Note:** {*AI95-00230-01*} For access parameters and access discriminants, the "storage pool" for an anonymous access type would not normally exist as a separate entity. Instead, the designated object of the allocator would be allocated, in the case of an access parameter, as a local aliased variable at the call site, and in the case of an access discriminant, contiguous with the object containing the discriminant. This is similar to the way storage for aggregates is typically managed.

25.b/2 {*AI95-00230-01*} For other sorts of anonymous access types, this implementation is not possible in general, as the accessibility of the anonymous access type is that of its declaration, while the allocator could be more nested. In this case, a "real" storage pool is required. Note, however, that this storage pool need not support (separate) deallocation, as it is not possible to instantiate Unchecked_Deallocation with an anonymous access type. (If deallocation is needed, the object should be allocated for a named access type and converted.) Thus, deallocation only need happen when the anonymous access type itself goes out of scope; this is similar to the case of an access-to-constant type.

26/5 NOTE 1 {*AI12-0442-1*} A user-defined storage pool type can be obtained by extending the Root_Storage_Pool type, and overriding the primitive subprograms Allocate, Deallocate, and Storage_Size. A user-defined storage pool can then be obtained by declaring an object of the type extension. The user can override Initialize and Finalize if there is any desire for nontrivial initialization and finalization for a user-defined pool type. For example, Finalize can reclaim blocks of storage that are allocated separately from the pool object itself.

27 NOTE 2 The writer of the user-defined allocation and deallocation procedures, and users of allocators for the associated access type, are responsible for dealing with any interactions with tasking. In particular:

28 • If the allocators are used in different tasks, they require mutual exclusion.

29 • If they are used inside protected objects, they cannot block.

30 • If they are used by interrupt handlers (see C.3, “Interrupt Support”), the mutual exclusion mechanism has to work properly in that context.

31 NOTE 3 The primitives Allocate, Deallocate, and Storage_Size are declared as abstract (see 3.9.3), and therefore they have to be overridden when a new (nonabstract) storage pool type is declared.

31.a **Ramification:** Note that the Storage_Pool attribute denotes an object, rather than a value, which is somewhat unusual for attributes.

31.b The calls to Allocate, Deallocate, and Storage_Size are dispatching calls — this follows from the fact that the actual parameter for Pool is T'Storage_Pool, which is of type Root_Storage_Pool'Class. In many cases (including all cases in which Storage_Pool is not specified), the compiler can determine the tag statically. However, it is possible to construct cases where it cannot.

31.c All access types in the same derivation class share the same pool, whether implementation defined or user defined. This is necessary because we allow type conversions among them (even if they are pool-specific), and we want pool-specific access values to always designate an element of the right pool.

31.d **Implementation Note:** If an access type has a standard storage pool, then the implementation doesn't actually have to follow the pool interface described here, since this would be semantically invisible. For example, the allocator could conceivably be implemented with inline code.

Examples

32 To associate an access type with a storage pool object, the user first declares a pool object of some type derived from Root_Storage_Pool. Then, the user defines its Storage_Pool attribute, as follows:

33
```
Pool_Object : Some_Storage_Pool_Type;
```

34
```
type T is access Designated;
for T'Storage_Pool use Pool_Object;
```

35/5 {*AI12-0440-1*} Another access type can be added to an existing storage pool, via:

```
for T2'Storage_Pool use T'Storage_Pool;
```

The semantics of this is implementation defined for a standard storage pool.

Reason: For example, the implementation is allowed to choose a storage pool for T that takes advantage of the fact that T is of a certain size. If T2 is not of that size, then the above will probably not work.

{*AI05-0111-3*} {*AI12-0440-1*} As usual, a derivative of Root_Storage_Pool can define additional operations. For example, consider the Mark_Release_Pool_Type defined in 13.11.6, that has two additional operations, Mark and Release, the following is a possible use:

```
{8652/0041} {AI95-00066-01} {AI05-0111-3} type Mark_Release_Pool_Type
   (Pool_Size : Storage_Elements.Storage_Count)
        is new Subpools.Root_Storage_Pool_With_Subpools with private;
           -- As defined in package MR_Pool, see 13.11.6

...

{AI05-0111-3} {AI12-0178-1} Our_Pool : Mark_Release_Pool_Type (Pool_Size => 2000);
My_Mark : Subpool_Handle; -- As declared in 13.11.6

{AI05-0111-3} type Acc is access ...;
for Acc'Storage_Pool use Our_Pool;
...

{AI05-0111-3} My_Mark := Mark(Our_Pool);
... -- Allocate objects using "new (My_Mark) Designated(...)".
Release(My_Mark); -- Finalize objects and reclaim storage.
```

Extensions to Ada 83

User-defined storage pools are new to Ada 95.

Wording Changes from Ada 83

{*AI05-0005-1*} {*AI05-0190-1*} Ada 83 originally introduced the concept called a "collection", which is similar to what we call a storage pool. All access types in the same derivation class share the same collection. Ada 95 introduces the storage pool, which is similar in that all access types in the same derivation class share the same storage pool, but other (unrelated) access types can also share the same storage pool, either by default, or as specified by the user. A collection is an amorphous grouping of objects (mainly used to describe finalization of access types); a storage pool is a more concrete concept — hence the different name.

RM83 states the erroneousness of reading or updating deallocated objects incorrectly by missing various cases.

Incompatibilities With Ada 95

{*AI95-00435-01*} **Amendment Correction:** Storage pools (and Storage_Size) are not defined for access-to-subprogram types. The original Ada 95 wording defined the attributes, but said nothing about their values. If a program uses attributes Storage_Pool or Storage_Size on an access-to-subprogram type, it will need to be corrected for Ada 2005. That's a good thing, as such a use is a bug — the concepts never were defined for such types.

Extensions to Ada 95

{*AI95-00161-01*} **Amendment Correction:** Added pragma Preelaborable_Initialization to type Root_Storage_Pool, so that extensions of it can be used to declare default-initialized objects in preelaborated units.

Wording Changes from Ada 95

{*8652/0009*} {*AI95-00137-01*} **Corrigendum:** Added wording to specify that these are representation attributes.

{*AI95-00230-01*} {*AI95-00416-01*} Added wording to clarify that an allocator for a coextension nested inside an outer allocator shares the pool with the outer allocator.

Wording Changes from Ada 2005

{*AI05-0051-1*} **Correction:** Added the missing definition of the storage pool of an allocator for an anonymous access result type.

{*AI05-0107-1*} **Correction:** Clarified when an implementation is allowed to call Allocate and Deallocate, and the requirements on such calls.

{*AI05-0111-3*} Added wording to support subpools and refer to the subpool example, see 13.11.4.

43.k/3 {*AI05-0116-1*} **Correction:** Added wording to specify that the alignment for an allocator with a class-wide designated type comes from the specific type that is allocated.

43.l/3 {*AI05-0193-1*} Added wording to allow larger alignments for calls to Allocate made by allocators, up to Max_Alignment_For_Allocation. This eases implementation in some cases.

Extensions to Ada 2012

43.m/5 {*AI12-0235-1*} Package System.Storage_Pools now has Pure categorization, so it can be mentioned for any package. Note that this does not allow storage pool objects to be shared between partitions, as these necessarily must be variables; however, this does allow a storage pool type to be shared.

Wording Changes from Ada 2012

43.n/4 {*AI12-0043-1*} **Corrigendum:** Tightened up the description of the implementation-defined pool used when Storage_Size is specified. This is not intended to change any implementation.

43.o/5 {*AI12-0319-1*} {*AI12-0424-1*} Specified that the standard pool(s), and the pool(s) used to implement a specified Storage_Size, are nonblocking and support concurrent use. This was always true (which is why this is not documented as an incompatibility), but it never was explicitly stated before. In the past, the absence of wording defining something to be potentially blocking determined if blocking was not allowed. Similarly, the absence of a statement that allocation was not allowed in multiple tasks implied that it was allowed.

13.11.1 Storage Allocation Attributes

1/3 {*AI05-0193-1*} [The Max_Size_In_Storage_Elements and Max_Alignment_For_Allocation attributes may be useful in writing user-defined pool types.]

Static Semantics

2/3 {*AI05-0193-1*} For every subtype S, the following attributes are defined:

3/5 S'Max_Size_In_Storage_Elements

{*AI95-00256-01*} {*AI95-00416-01*} {*AI05-0193-1*} {*AI12-0439-1*} Denotes the maximum value for Size_In_Storage_Elements that can be requested by the implementation via Allocate for an access type whose designated subtype is S. The value of this attribute is of type *universal_integer*.

3.a **Ramification:** If S is an unconstrained array subtype, or an unconstrained subtype with discriminants, S'Max_Size_In_Storage_Elements might be very large.

4/5 S'Max_Alignment_For_Allocation

{*AI05-0193-1*} {*AI12-0439-1*} Denotes the maximum value for Alignment that can be requested by the implementation via Allocate for an access type whose designated subtype is S. The value of this attribute is of type *universal_integer*.

5/5 {*AI05-0193-1*} {*AI12-0439-1*} For a type with access discriminants, if the implementation allocates space for a coextension in the same pool as that of the object having the access discriminant, then these attributes account for any calls on Allocate that can be performed to provide space for such coextensions.

5.a/3 **Reason:** {*AI05-0193-1*} The values of these attributes should reflect only the calls that might be made to the pool specified for an access type with designated type S. Thus, if the coextensions would normally be allocated from a different pool than the one used for the main object (that is, the Implementation Advice of 13.11 for determining the pool of an anonymous access discriminant is not followed), then these attributes should not reflect any calls on Allocate used to allocate the coextensions.

5.b/3 **Ramification:** {*AI05-0193-1*} Coextensions of coextensions of this type (and so on) are included in the values of these attributes if they are allocated from the same pool.

Wording Changes from Ada 95

5.c/2 {*AI95-00256-01*} Corrected the wording so that a fortune-telling compiler that can see the future execution of the program is not required.

Extensions to Ada 2005

{*AI05-0193-1*} The Max_Alignment_For_Allocation attribute is new. 5.d/3

13.11.2 Unchecked Storage Deallocation

[Unchecked storage deallocation of an object designated by a value of an access type is achieved by a call to an instance of the generic procedure Unchecked_Deallocation.] 1

Static Semantics

The following language-defined generic library procedure exists: 2

```
{AI05-0229-1} {AI12-0241-1} {AI12-0302-1} {AI12-0319-1} generic                    3/5
   type Object(<>) is limited private;
   type Name   is access  Object;
procedure Ada.Unchecked_Deallocation(X : in out Name)
   with Preelaborate, Nonblocking,
        Global => in out Name'Storage_Pool,
        Convention => Intrinsic;
```

Reason: {*AI05-0229-1*} The aspect Convention implies that the attribute Access is not allowed for instances of Unchecked_Deallocation. 3.a/3

Legality Rules

{*AI05-0157-1*} A call on an instance of Unchecked_Deallocation is illegal if the actual access type of the instance is a type for which the Storage_Size has been specified by a static expression with value zero or is defined by the language to be zero. In addition to the places where Legality Rules normally apply (see 12.3), this rule applies also in the private part of an instance of a generic unit. 3.1/3

Discussion: This rule is the same as the rule for allocators. We could have left the last sentence out, as a call to Unchecked_Deallocation cannot occur in a specification as it is a procedure call, but we left it for consistency and to avoid future maintenance hazards. 3.b/3

Dynamic Semantics

Given an instance of Unchecked_Deallocation declared as follows: 4

```
procedure Free is                                                                  5
    new Ada.Unchecked_Deallocation(
        object_subtype_name, access_to_variable_subtype_name);
```

Procedure Free has the following effect: 6

1. After executing Free(X), the value of X is **null**. 7
2. Free(X), when X is already equal to **null**, has no effect. 8
3. {*AI95-00416-01*} {*AI05-0107-1*} {*AI12-0445-1*} Free(X), when X is not equal to **null** first performs finalization of the object designated by X (and any coextensions of the object — see 3.10.2), as described in 7.6.1. It then deallocates the storage occupied by the object designated by X (and any coextensions). If the storage pool is a user-defined object, then the storage is deallocated by calling Deallocate as described in 13.11. There is one exception: if the object being freed contains tasks, it is unspecified whether the object is deallocated. 9/5

Ramification: {*AI05-0107-1*} Free calls only the specified Deallocate procedure to do deallocation. 9.a/3

{*AI95-00416-01*} {*AI12-0148-1*} After the finalization step of Free(X), the object designated by X, and any subcomponents (and coextensions) thereof, no longer exist; their storage can be reused for other purposes. 10/4

Bounded (Run-Time) Errors

It is a bounded error to free a discriminated, unterminated task object. The possible consequences are: 11

11.a **Reason:** This is an error because the task might refer to its discriminants, and the discriminants might be deallocated by freeing the task object.

12 • No exception is raised.

13 • Program_Error or Tasking_Error is raised at the point of the deallocation.

14 • Program_Error or Tasking_Error is raised in the task the next time it references any of the discriminants.

14.a **Implementation Note:** This last case presumes an implementation where the task references its discriminants indirectly, and the pointer is nulled out when the task object is deallocated.

15 In the first two cases, the storage for the discriminants (and for any enclosing object if it is designated by an access discriminant of the task) is not reclaimed prior to task termination.

15.a **Ramification:** The storage might never be reclaimed.

15.1/4 {*AI12-0148-1*} An access value that designates a nonexistent object is called a *dangling reference*.

15.b/4 **Discussion:** These can result from use of Unchecked_Deallocation, Unchecked_Deallocate_Subpool, and attribute Unchecked_Access. Bad results from Unchecked_Conversion and from stream-oriented attributes are abnormal by 13.9.1, which is stronger and thus takes precedence.

15.2/4 {*AI12-0148-1*} [If a dangling reference is dereferenced (implicitly or explicitly), execution is erroneous (see below).] If there is no explicit or implicit dereference, then it is a bounded error to evaluate an expression whose result is a dangling reference. If the error is detected, either Constraint_Error or Program_Error is raised. Otherwise, execution proceeds normally, but with the possibility that the access value designates some other existing object.

15.c/4 **Reason:** If a dangling reference is compared with another access value, a result of either True or False is allowed. We need to allow this so that simple implementations of access values (for instance, as a bare address) can work if the memory in question is reused. (The formal definition of access equality is that it returns True if both access values designate the same object; that can never be True if one of the values is a dangling reference, and the other is not, but both values could refer to the same memory.) Membership tests that do not involve an implicit dereference generally do not depend on the access value at all.

15.d/4 We allow Constraint_Error to be raised here so that dangling reference and null pointer checks can be combined into a single check. If different exceptions are required, then the checks have to be made separately - but there's little semantic difference (neither designate a usable object).

15.e/4 **Ramification:** If a dangling reference is assigned into an object, including being passed to a formal parameter, that object also contains a dangling reference afterwards.

15.f/4 **Discussion:** For equality and membership operations on composite types, this applies to any parts that are access types, as these operations are created based on the operations of the components (which triggers the bounded error). For other operations on composite types, the bounded error is not triggered. For instance, an assignment of a composite object with a subcomponent that is a dangling reference has to work normally; no exception can be raised, but the target object will have a subcomponent that is a dangling references, and a (direct) use of that subcomponent is again a bounded error. This is similar to the way that assignments of invalid subcomponents are handled (see 13.9.1).

Erroneous Execution

16/3 {*AI05-0033-1*} {*AI05-0262-1*} Evaluating a name that denotes a nonexistent object, or a protected subprogram or subprogram renaming whose associated object (if any) is nonexistent, is erroneous. The execution of a call to an instance of Unchecked_Deallocation is erroneous if the object was created other than by an allocator for an access type whose pool is Name'Storage_Pool.

16.a/3 **Reason:** {*AI05-0033-1*} {*AI05-0262-1*} The part about a protected subprogram is intended to cover the case of an access-to-protected-subprogram where the associated object has been deallocated. The part about a subprogram renaming is intended to cover the case of a renaming of a prefixed view where the prefix object has been deallocated, or the case of a renaming of an entry or protected subprogram where the associated task or protected object has been deallocated.

16.b/3 **Ramification:** {*AI05-0157-1*} This text does not cover the case of a name that contains a null access value, as **null** does not denote an object (rather than denoting a nonexistent object).

Implementation Advice

For a standard storage pool, Free should actually reclaim the storage. 17

Implementation Advice: For a standard storage pool, an instance of Unchecked_Deallocation should actually reclaim the storage. 17.a.1/2

Ramification: {*AI95-00114-01*} This is not a testable property, since we do not know how much storage is used by a given pool element, nor whether fragmentation can occur. 17.a/2

{*AI05-0157-1*} A call on an instance of Unchecked_Deallocation with a nonnull access value should raise Program_Error if the actual access type of the instance is a type for which the Storage_Size has been specified to be zero or is defined by the language to be zero. 17.1/3

Implementation Advice: A call on an instance of Unchecked_Deallocation with a nonnull access value should raise Program_Error if the actual access type of the instance is a type for which the Storage_Size has been specified to be zero or is defined by the language to be zero. 17.a.1/3

Discussion: If the call is not illegal (as in a generic body), we recommend that it raise Program_Error. Since the execution of this call is erroneous (any allocator from the pool will have raised Storage_Error, so the nonnull access value must have been allocated from a different pool or be a stack-allocated object), we can't require any behavior — anything at all would be a legitimate implementation. 17.b

NOTE 1 The rules here that refer to Free apply to any instance of Unchecked_Deallocation. 18

NOTE 2 Unchecked_Deallocation cannot be instantiated for an access-to-constant type. This is implied by the rules of 12.5.4. 19

Wording Changes from Ada 95

{*AI95-00416-01*} The rules for coextensions are clarified (mainly by adding that term). In theory, this reflects no change from Ada 95 (coextensions existed in Ada 95, they just didn't have a name). 19.a/2

Wording Changes from Ada 2005

{*AI05-0033-1*} **Correction:** Added a rule that using an access-to-protected-subprogram is erroneous if the associated object no longer exists. It is hard to imagine an alternative meaning here, and this has no effect on correct programs. 19.b/3

{*AI05-0107-1*} **Correction:** Moved the requirements on an implementation-generated call to Deallocate to 13.11, in order to put all of the rules associated with implementation-generated calls to Allocate and Deallocate together. 19.c/3

{*AI05-0157-1*} **Correction:** Added wording so that calling an instance of Unchecked_Deallocation is treated similarly to allocators for access types where allocators would be banned. 19.d/3

Inconsistencies With Ada 2012

{*AI12-0148-1*} **Corrigendum:** Defined a "dangling reference", and specified that a dangling reference might designate some other existing object. This allows simple implementations of access values and reuse of object memory after deallocation. In prior versions of Ada, "=" between a dangling reference and an access to an existing object has to return False, even if the existing object and the object designated by the dangling reference are allocated in the same memory. A program that depended upon that could break with this revised rule. However, as a practical matter, almost all Ada implementations use simple implementations of access types that do not meet that requirement. So such a program would not work (consistently) on most Ada implementations; thus the change shouldn't break any existing programs - it just aligns the Standard with actual practice. 19.e/4

{*AI12-0148-1*} A side effect of this change is to allow an Ada implementation to detect dangling references in more places. This does not require any Ada implementation to change, and if the implementation does change, it just means that errors will be detected earlier. 19.f/4

Wording Changes from Ada 2012

{*AI12-0148-1*} **Corrigendum:** Clarified that deallocated objects cease to exist after finalization but before Deallocate is called. This is necessary to prevent erroneous execution from being triggered by the rules in 13.11 in the time between the end of finalization and the end of the call to the instance of Unchecked_Deallocation. 19.g/4

13.11.3 Default Storage Pools

1/4 {*AI05-0229-1*} {*AI12-0003-1*} [Pragma and aspect Default_Storage_Pool specify the storage pool that will be used in the absence of an explicit specification of a storage pool or storage size for an access type.]

Syntax

2/3 {*AI05-0190-1*} {*AI05-0229-1*} The form of a pragma Default_Storage_Pool is as follows:

3/3 {*AI05-0190-1*} {*AI05-0229-1*} **pragma** Default_Storage_Pool (storage_pool_indicator);

3.1/4 {*AI05-0190-1*} {*AI12-0003-1*} storage_pool_indicator ::= *storage_pool_*name | **null** | Standard

3.2/3 {*AI05-0190-1*} A pragma Default_Storage_Pool is allowed immediately within the visible part of a package_specification, immediately within a declarative_part, or as a configuration pragma.

Name Resolution Rules

3.3/3 {*AI05-0190-1*} The *storage_pool_*name is expected to be of type Root_Storage_Pool'Class.

Legality Rules

4/3 {*AI05-0190-1*} {*AI05-0229-1*} The *storage_pool_*name shall denote a variable.

4.1/4 {*AI12-0003-1*} The Standard storage_pool_indicator is an identifier specific to a pragma (see 2.8) and does not denote any declaration. If the storage_pool_indicator is Standard, then there shall not be a declaration with defining_identifier Standard that is immediately visible at the point of the pragma, other than package Standard itself.

4.a.1/4 **Reason:** We considered having the Standard storage_pool_indicator resolve to package Standard rather than being an identifier specific to a pragma. That would eliminate the need for a special check. But it would be bizarre to have something that could resolve to either an object or a (single) package, and resolving to package Standard would imply that the standard pool is an object declared in that package. A storage pool object must be a variable (see 13.11), yet preelaborable packages depend on package Standard, which would require implementers to implement the standard storage pool with Preelaborable_Initialization, which is an unnecessary restriction.

4.a.2/4 No declaration of Standard can ever be use-visible, as the language-defined nonoverloadable definition of Standard will hide any use-visible declarations. Thus we need only concern ourselves with eliminating any possible confusion with regard to immediately visible declarations with the defining_identifier Standard.

4.2/4 {*AI05-0190-1*} {*AI12-0003-1*} If the pragma is used as a configuration pragma, the storage_pool_indicator shall be either **null** or Standard, and it defines the *default pool* to be the given storage_pool_indicator within all applicable compilation units (see 10.1.5), except within the immediate scope of another pragma Default_Storage_Pool. Otherwise, [the pragma occurs immediately within a sequence of declarations, and] it defines the default pool within the immediate scope of the pragma to be the given storage_pool_indicator, except within the immediate scope of a later pragma Default_Storage_Pool. [Thus, an inner pragma overrides an outer one.]

4.3/4 {*AI05-0190-1*} {*AI05-0262-1*} A pragma Default_Storage_Pool shall not be used as a configuration pragma that applies to a compilation unit that is within the immediate scope of another pragma Default_Storage_Pool.

4.a/3 **Reason:** This is to prevent confusion in cases like this:

4.b/3
```
package Parent is
   pragma Default_Storage_Pool(...);
   ...
end Parent;
```

```
pragma Default_Storage_Pool(...); -- Illegal!
package Parent.Child is
   ...
end Parent.Child;
```

where the Default_Storage_Pool on Parent.Child would not (if it were legal) override the one in Parent. 4.d/3

Static Semantics

{*AI05-0190-1*} {*AI05-0229-1*} {*AI12-0003-1*} The language-defined aspect Default_Storage_Pool may be specified for a generic instance; it defines the default pool for access types within an instance. . 5/4

{*AI12-0003-1*} The Default_Storage_Pool aspect may be specified as Standard, which is an identifier specific to an aspect (see 13.1.1) and defines the default pool to be Standard. In this case, there shall not be a declaration with defining_identifier Standard that is immediately visible at the point of the aspect specification, other than package Standard itself. 5.1/4

{*AI12-0003-1*} {*AI12-0445-1*} Otherwise, the expected type for the Default_Storage_Pool aspect is Root_Storage_Pool'Class and the aspect_definition shall be a name that denotes a variable. This aspect overrides any Default_Storage_Pool pragma that applies to the generic unit; if the aspect is not specified, the default pool of the instance is that defined for the generic unit. 5.2/5

Aspect Description for Default_Storage_Pool: Default storage pool for a generic instance. 5.a/3

{*AI12-0136-1*} The effect of specifying the aspect Default_Storage_Pool on an instance of a language-defined generic unit is implementation-defined. 5.3/4

Implementation defined: The effect of specifying aspect Default_Storage_Pool on an instance of a language-defined generic unit. 5.a.1/4

{*AI05-0190-1*} {*AI05-0229-1*} For nonderived access types declared in places where the default pool is defined by the pragma or aspect, their Storage_Pool or Storage_Size attribute is determined as follows, unless Storage_Pool or Storage_Size is specified for the type: 6/3

- {*AI05-0190-1*} If the default pool is **null**, the Storage_Size attribute is defined by the language to be zero. [Therefore, an allocator for such a type is illegal.] 6.1/3
- {*AI05-0190-1*} {*AI12-0003-1*} If the default pool is neither **null** nor Standard, the Storage_Pool attribute is that pool. 6.2/4

{*AI05-0190-1*} {*AI12-0003-1*} Otherwise (including when the default pool is specified as Standard), the standard storage pool is used for the type as described in 13.11. 6.3/4

Ramification: {*AI05-0190-1*} {*AI05-0229-1*} Default_Storage_Pool is the only way to specify the storage pool for an anonymous access type. 6.a/3

{*AI05-0190-1*} {*AI05-0229-1*} Note that coextensions should be allocated in the same pool (or on the stack) as the outer object (see 13.11); the Storage_Pool of the access discriminant (and hence the Default_Storage_Pool) is supposed to be ignored for coextensions. This matches the required finalization point for coextensions. 6.b/3

{*AI05-0190-1*} The default storage pool for an allocator that occurs within an instance of a generic is defined by the Default_Storage_Pool aspect of the instantiation (if specified), or by the Default_Storage_Pool pragma that applied to the generic; the Default_Storage_Pool pragma that applies to the instantiation is irrelevant. 6.b.1/3

{*AI05-0190-1*} It is possible to specify the Default_Storage_Pool aspect for an instantiation such that allocations will fail. For example, the generic unit might be expecting a pool that supports certain sizes and alignments, and the one on the instance might be more restrictive. It is the programmer's responsibility to get this right. 6.b.2/3

{*AI05-0190-1*} The semantics of the Default_Storage_Pool aspect are similar to passing a pool object as a generic formal, and putting pragma Default_Storage_Pool at the top of the generic's visible part, specifying that formal. 6.b.3/3

This paragraph was deleted.{*AI05-0229-1*} 7/3

Implementation Permissions

8/3 {*AI05-0190-1*} {*AI05-0229-1*} An object created by an allocator that is passed as the actual parameter to an access parameter may be allocated on the stack, and automatically reclaimed, regardless of the default pool.

8.a/3 **Discussion:** {*AI05-0190-1*} This matches the required finalization point for such an allocated object.

9/5 NOTE {*AI05-0190-1*} {*AI12-0440-1*} Default_Storage_Pool can be used with restrictions No_Coextensions and No_Access_Parameter_Allocators (see H.4) to ensure that all allocators use the default pool.

Wording Changes from Ada 83

9.a/3 *This paragraph was deleted.*{*AI05-0229-1*}

Incompatibilities With Ada 2005

9.b/3 {*AI05-0229-1*} Pragma Controlled has been dropped from Ada, as it has no effect in any known Ada implementations and it seems to promise capabilities not expected in Ada implementations. This is usually not an incompatibility, as the pragma merely becomes unrecognized (with a warning) and can be implemented as an implementation-defined pragma if desired. However, it is incompatible if it is (now) implemented as an implementation-defined pragma, someone used this pragma in a unit, and they also used restriction No_Implementation_Pragmas on that unit. In that case, the pragma would now violate the restriction; but use of this pragma (which does nothing) should be very rare, so this is not a significant issue.

Extensions to Ada 2005

9.c/4 {*AI05-0190-1*} {*AI12-0005-1*} The pragma Default_Storage_Pool and aspect Default_Storage_Pool are new.

Wording Changes from Ada 2005

9.d/3 {*AI05-0229-1*} The entire discussion of garbage collection (and especially that of controlled objects) is deleted. Ada 2012 provides subpools (see 13.11.4) for storage management of objects, including controlled objects, a mechanism which is much more predictable than garbage collection. Note that no version of Ada allows early finalization of controlled objects (other than via the use of Unchecked_Deallocation or Unchecked_Deallocate_Subpool), so that garbage collection of such objects would be ineffective in the standard mode anyway.

Extensions to Ada 2012

9.e/4 {*AI05-0003-1*} **Corrigendum:** The storage_pool_indicator Standard is new.

Wording Changes from Ada 2012

9.f/4 {*AI12-0136-1*} **Corrigendum:** We now explicitly say that the behavior of language-defined generic units when given the Default_Storage_Pool aspect is implementation-defined. Portable code cannot rely on such a package using a particular pool implementation.

13.11.4 Storage Subpools

1/3 {*AI05-0111-3*} This subclause defines a package to support the partitioning of a storage pool into subpools. A subpool may be specified as the default to be used for allocation from the associated storage pool, or a particular subpool may be specified as part of an allocator (see 4.8).

Static Semantics

2/3 {*AI05-0111-3*} The following language-defined library package exists:

3/5
```
{AI12-0302-1} package System.Storage_Pools.Subpools
    with Preelaborate, Global => in out synchronized is
```

4/5
```
{AI12-0356-1} {AI12-0399-1}    type Root_Storage_Pool_With_Subpools is
      abstract new Root_Storage_Pool with private
      with Preelaborable_Initialization;
```

5/5
```

   ... -- not specified by the language
end System.Storage_Pools.Subpools;
```

{*AI05-0111-3*} A *subpool* is a separately reclaimable portion of a storage pool, identified by an object of type Subpool_Handle (a *subpool handle*). A subpool handle also identifies the enclosing storage pool, a *storage pool that supports subpools*, which is a storage pool whose type is descended from Root_Storage_Pool_With_Subpools. A subpool is created by calling Create_Subpool or a similar constructor; the constructor returns the subpool handle. 18/3

{*AI05-0111-3*} {*AI05-0269-1*} {*AI12-0445-1*} A *subpool object* is an object of a type descended from Root_Subpool. [Typically, subpool objects are managed by the containing storage pool; only the handles have to be exposed to clients of the storage pool. Subpool objects are designated by subpool handles, and are the run-time representation of a subpool.] 19/5

Proof: We know that subpool handles designate subpool objects because the declaration of Subpool_Handle says so. 19.a/3

20/4 {*AI05-0111-3*} {*AI12-0145-1*} Each subpool *belongs* to a single storage pool [(which will always be a pool that supports subpools)]. An access to the pool that a subpool belongs to can be obtained by calling Pool_of_Subpool with the subpool handle. Set_Pool_of_Subpool causes the subpool of the subpool handle to belong to the given pool[; this is intended to be called from subpool constructors like Create_Subpool.] Set_Pool_of_Subpool propagates Program_Error if the subpool already belongs to a pool. If Set_Pool_of_Subpool has not yet been called for a subpool, Pool_of_Subpool returns **null**.

20.a/3 **Discussion:** Pool_of_Subpool and Set_Pool_of_Subpool are provided by the Ada implementation and typically will not be overridden by the pool implementer.

21/3 {*AI05-0111-3*} When an allocator for a type whose storage pool supports subpools is evaluated, a call is made on Allocate_From_Subpool passing in a Subpool_Handle, in addition to the parameters as defined for calls on Allocate (see 13.11). The subpool designated by the *subpool_handle_*name is used, if specified in an allocator. Otherwise, Default_Subpool_for_Pool of the Pool is used to provide a subpool handle. All requirements on the Allocate procedure also apply to Allocate_from_Subpool.

21.a/3 **Discussion:** Deallocate_Subpool is expected to do whatever is needed to deallocate all of the objects contained in the subpool; it is called from Unchecked_Deallocate_Subpool (see 13.11.5).

21.b/3 Typically, the pool implementer will not override Allocate. In the canonical definition of the language, it will never be called for a pool that supports subpools (there is an Implementation Permission below that allows it to be called in certain rare cases).

Legality Rules

22/3 {*AI05-0111-3*} If a storage pool that supports subpools is specified as the Storage_Pool for an access type, the access type is called a *subpool access type*. A subpool access type shall be a pool-specific access type.

23/3 {*AI05-0111-3*} {*AI05-0252-1*} The accessibility level of a subpool access type shall not be statically deeper than that of the storage pool object. If the specified storage pool object is a storage pool that supports subpools, then the name that denotes the object shall not denote part of a formal parameter, nor shall it denote part of a dereference of a value of a non-library-level general access type. In addition to the places where Legality Rules normally apply (see 12.3), these rules also apply in the private part of an instance of a generic unit.

Dynamic Semantics

24/3 {*AI05-0111-3*} {*AI05-0252-1*} When an access type with a specified storage pool is frozen (see 13.14), if the tag of the storage pool object identifies a storage pool that supports subpools, the following checks are made:

25/3 - the name used to specify the storage pool object does not denote part of a formal parameter nor part of a dereference of a value of a non-library-level general access type; and

26/3 - the accessibility level of the access type is not deeper than that of the storage pool object.

27/3 {*AI05-0252-1*} Program_Error is raised if either of these checks fail.

27.a/3 **Reason:** This check (and its static counterpart) ensures that the type of the allocated objects exists at least as long as the storage pool object, so that the subpools are finalized (which finalizes any remaining allocated objects) before the type of the objects ceases to exist. The access type itself (and the associated collection) will cease to exist before the storage pool ceases to exist.

27.b/3 We also disallow the use of formal parameters and dereferences of non-library-level general access types when specifying a storage pool object if it supports subpools, because the "apparent" accessibility level is potentially deeper than that of the underlying object. Neither of these cases is very likely to occur in practice.

28/3 {*AI05-0111-3*} A call to Subpools.Allocate(P, Addr, Size, Align) does the following:

```
Allocate_From_Subpool                                                    29/3
  (Root_Storage_Pool_With_Subpools'Class(P),
   Addr, Size, Align,
   Subpool => Default_Subpool_for_Pool
                (Root_Storage_Pool_With_Subpools'Class(P)));
```

{*AI05-0111-3*} An allocator that allocates in a subpool raises Program_Error if the allocated object has task parts. 30/3

Reason: This is to ease implementation. We envision relaxing this restriction in a future version of Ada, once implementation experience has been gained. At this time, we are unable to come up with a set of rules for task termination that is both useful, and surely feasible to implement. 30.a/3

{*AI05-0111-3*} Unless overridden, Default_Subpool_for_Pool propagates Program_Error. 31/3

Erroneous Execution

{*AI12-0142-1*} If Allocate_From_Subpool does not meet one or more of the requirements on the Allocate procedure as given in the Erroneous Execution rules of 13.11, then the program execution is erroneous. 31.1/4

Implementation Permissions

{*AI05-0111-3*} When an allocator for a type whose storage pool is of type Root_Storage_Pool'Class is evaluated, but supports subpools, the implementation may call Allocate rather than Allocate_From_Subpool. [This will have the same effect, so long as Allocate has not been overridden.] 32/3

Reason: This ensures either of two implementation models are possible for an allocator with no subpool_specification. Note that the "supports subpools" property is not known at compile time for a pool of the class-wide type. 32.a/3

- The implementation can dispatch to Storage_Pools.Allocate. If the pool supports subpools, this will call Allocate_From_Subpool with the default subpool so long as Allocate has not been overridden. 32.b/3
- The implementation can declare Allocate_From_Subpool as a primitive of Root_Storage_Pool in the private part of Storage_Pools. This means that the Allocate_From_Subpool for Root_Storage_Pool_With_Subpools overrides that private one. The implementation can thus call the private one, which will call Allocate for non-subpool-supporting pools. The effect of this implementation does not change if Allocate is overridden for a pool that supports subpools. 32.c/3

NOTE 1 {*AI05-0111-3*} {*AI12-0442-1*} {*AI12-0447-1*} A user-defined storage pool type that supports subpools can be implemented by extending the Root_Storage_Pool_With_Subpools type, and overriding the primitive subprograms Create_Subpool, Allocate_From_Subpool, and Deallocate_Subpool. Create_Subpool is expected to call Set_Pool_Of_Subpool before returning the subpool handle. To make use of such a pool, a user can declare an object of the type extension, can use it to define the Storage_Pool attribute of one or more access types, and then can invoke Create_Subpool to obtain subpool handles associated with the pool. 33/5

NOTE 2 {*AI05-0111-3*} {*AI12-0440-1*} A user-defined storage pool type that supports subpools can define additional subpool constructors similar to Create_Subpool (these typically will have additional parameters). 34/5

NOTE 3 {*AI05-0111-3*} {*AI12-0442-1*} The pool implementor can override Default_Subpool_For_Pool if they want the pool to support a default subpool for the pool. The implementor can override Deallocate if individual object reclamation is to be supported, and can override Storage_Size if there is some limit on the total size of the storage pool. The implementor can override Initialize and Finalize if there is any desire for nontrivial initialization and finalization for the pool as a whole. For example, Finalize can reclaim blocks of storage that are allocated over and above the space occupied by the pool object itself. The pool implementor can extend the Root_Subpool type as necessary to carry additional information with each subpool provided by Create_Subpool. 35/5

Extensions to Ada 2005

{*AI05-0111-3*} {*AI05-0252-1*} Subpools and the package System.Storage_Pools.Subpools are new. 35.a/3

Wording Changes from Ada 2012

{*AI12-0142-1*} **Corrigendum**: Clarified that an incorrect implementation of Allocate_From_Subpool causes execution to become erroneous. The wording already said that the requirements of Allocate apply to Allocate_From_Subpool, so we're just confirming the consequences of violating those requirements also apply. 35.b/4

35.c/4 {*AI12-0145-1*} **Corrigendum**: Clarified that Pool_of_Subpool returns **null** if Set_Pool_of_Subpool has not been called. As that can be inferred from the definition, and all known existing implementations return **null** in this case, we document this as a wording change rather than a possible inconsistency.

13.11.5 Subpool Reclamation

1/3 {*AI05-0111-3*} A subpool may be explicitly deallocated using Unchecked_Deallocate_Subpool.

Static Semantics

2/3 {*AI05-0111-3*} The following language-defined library procedure exists:

3/5
```
{AI12-0302-1} with System.Storage_Pools.Subpools;
procedure Ada.Unchecked_Deallocate_Subpool
   (Subpool : in out System.Storage_Pools.Subpools.Subpool_Handle)
   with Global => in out all;
```

3.a/5 **Discussion:** {*AI12-0005-1*} {*AI12-0302-1*} The Global specification for this routine needs to account for the dispatching call to the user-defined Deallocate_Subpool routine. We can't use the Dispatching aspect (see H.7.1) as that requires a statically named object (we have a function call here), so we have to use **in out all** in order to allow the user-defined subprogram to do anything it needs to do.

4/3 {*AI05-0111-3*} If Subpool is **null**, a call on Unchecked_Deallocate_Subpool has no effect. Otherwise, the subpool is finalized, and Subpool is set to **null**.

5/5 {*AI05-0111-3*} {*AI12-0331-1*} Finalization of a subpool has the following effects in the given order:

6/5 *This paragraph was deleted.*{*AI12-0331-1*}

7/3 1. Any of the objects allocated from the subpool that still exist are finalized in an arbitrary order;

7.1/4 2. {*AI12-0148-1*} All of the objects allocated from the subpool cease to exist;

8/3 3. The following [dispatching] call is then made:

9/3
```
Deallocate_Subpool(Pool_of_Subpool(Subpool).all, Subpool);
```

9.1/5 4. {*AI12-0331-1*} The subpool ceases to belong to any pool.

10/3 {*AI05-0111-3*} Finalization of a Root_Storage_Pool_With_Subpools object finalizes all subpools that belong to that pool that have not yet been finalized.

10.a/3 **Discussion:** There is no need to call Unchecked_Deallocation on an object allocated in a subpool. Such objects are deallocated all at once, when Unchecked_Deallocate_Subpool is called.

10.b/3 If Unchecked_Deallocation is called, the object is finalized, and then Deallocate is called on the Pool, which typically will do nothing. If it wants to free memory, it will need some way to get from the address of the object to the subpool.

10.c/3 There is no Deallocate_From_Subpool. There is no efficient way for the implementation to determine the subpool for an arbitrary object, and if the pool implementer can determine that, they can use that as part of the implementation of Deallocate.

10.d/3 If Unchecked_Deallocation is not called (the usual case), the object will be finalized when Unchecked_Deallocate_Subpool is called.

10.e/3 If that's never called, then the object will be finalized when the Pool_With_Subpools is finalized (by permission — it might happen when the collection of the access type is finalized).

Extensions to Ada 2005

10.f/3 {*AI05-0111-3*} Unchecked_Deallocate_Subpool is new.

Wording Changes from Ada 2012

10.g/4 {*AI12-0148-1*} **Corrigendum:** Added missing wording to state that the objects cease to exist after the completion of finalization. This is formally an inconsistency (it would be possible to depend on the fact that objects finalized by Unchecked_Deallocate_Subpool still exist), but that violates every sane expectation for a procedure called "Deallocate" something.

{*AI12-0331-1*} Clarified that the steps of deallocating a subpool occur in a specific order. This shouldn't change any implementation; no implementation is going to finalize deallocated objects or implement Unchecked_Deallocate_Subpool so it is certain to raise Constraint_Error. 10.h/5

13.11.6 Storage Subpool Example

Examples

{*AI05-0111-3*} The following example is a simple but complete implementation of the classic Mark/Release pool using subpools: 1/3

```
with System.Storage_Pools.Subpools;                                                    2/3
with System.Storage_Elements;
with Ada.Unchecked_Deallocate_Subpool;
package MR_Pool is

   use System.Storage_Pools;                                                           3/3
      -- For uses of Subpools.
   use System.Storage_Elements;
      -- For uses of Storage_Count and Storage_Array.

   -- Mark and Release work in a stack fashion, and allocations are not allowed       4/3
   -- from a subpool other than the one at the top of the stack. This is also
   -- the default pool.

   subtype Subpool_Handle is Subpools.Subpool_Handle;                                  5/3

   type Mark_Release_Pool_Type (Pool_Size : Storage_Count) is new                      6/3
      Subpools.Root_Storage_Pool_With_Subpools with private;

   function Mark (Pool : in out Mark_Release_Pool_Type)                                7/3
      return not null Subpool_Handle;

   procedure Release (Subpool : in out Subpool_Handle) renames                         8/3
      Ada.Unchecked_Deallocate_Subpool;

private                                                                                9/3

   type MR_Subpool is new Subpools.Root_Subpool with record                            10/3
      Start : Storage_Count;
   end record;
   subtype Subpool_Indexes is Positive range 1 .. 10;
   type Subpool_Array is array (Subpool_Indexes) of aliased MR_Subpool;

{AI05-0298-1} {AI12-0134-1}    type Mark_Release_Pool_Type (Pool_Size :             11/4
Storage_Count) is new
      Subpools.Root_Storage_Pool_With_Subpools with record
      Storage         : Storage_Array (0 .. Pool_Size);
      Next_Allocation : Storage_Count := 0;
      Markers         : Subpool_Array;
      Current_Pool    : Subpool_Indexes := 1;
   end record;

{AI05-0298-1}    overriding                                                          12/3
   function Create_Subpool (Pool : in out Mark_Release_Pool_Type)
      return not null Subpool_Handle;

   function Mark (Pool : in out Mark_Release_Pool_Type)                                13/3
      return not null Subpool_Handle renames Create_Subpool;

   overriding                                                                          14/3
   procedure Allocate_From_Subpool (
      Pool : in out Mark_Release_Pool_Type;
      Storage_Address : out System.Address;
      Size_In_Storage_Elements : in Storage_Count;
      Alignment : in Storage_Count;
      Subpool : not null Subpool_Handle);

   overriding                                                                          15/3
   procedure Deallocate_Subpool (
      Pool : in out Mark_Release_Pool_Type;
      Subpool : in out Subpool_Handle);
```

```
16/3     {AI05-0298-1}     overriding
            function Default_Subpool_for_Pool (Pool : in out Mark_Release_Pool_Type)
               return not null Subpool_Handle;
17/3        overriding

```

Wording Changes from Ada 2005

{*AI05-0111-3*} This example of subpools is new. 29.a/3

13.12 Pragma Restrictions and Pragma Profile

{*AI05-0246-1*} [A pragma Restrictions expresses the user's intent to abide by certain restrictions. A pragma Profile expresses the user's intent to abide by a set of Restrictions or other specified run-time policies. These may facilitate the construction of simpler run-time environments.] 1/3

Syntax

The form of a pragma Restrictions is as follows: 2

pragma Restrictions(restriction{, restriction}); 3

{*AI95-00381-01*} restriction ::= *restriction_*identifier 4/2
| *restriction_parameter_*identifier => restriction_parameter_argument

{*AI95-00381-01*} restriction_parameter_argument ::= name | expression 4.1/2

Name Resolution Rules

Unless otherwise specified for a particular restriction, the expression is expected to be of any integer type. 5

Legality Rules

Unless otherwise specified for a particular restriction, the expression shall be static, and its value shall be nonnegative. 6

This paragraph was deleted. 7.a/3

Paragraph 7 was deleted.

Post-Compilation Rules

8/3 {*AI05-0013-1*} A pragma Restrictions is a configuration pragma. If a pragma Restrictions applies to any compilation unit included in the partition, this may impose either (or both) of two kinds of requirements, as specified for the particular restriction:

8.1/3 - {*AI05-0013-1*} A restriction may impose requirements on some or all of the units comprising the partition. Unless otherwise specified for a particular restriction, such a requirement applies to all of the units comprising the partition and is enforced via a post-compilation check.

8.2/3 - {*AI05-0013-1*} A restriction may impose requirements on the run-time behavior of the program, as indicated by the specification of run-time behavior associated with a violation of the requirement.

8.a.1/3 **Ramification:** In this latter case, there is no post-compilation check needed for the requirement.

8.3/1 {*8652/0042*} {*AI95-00130-01*} For the purpose of checking whether a partition contains constructs that violate any restriction (unless specified otherwise for a particular restriction):

8.4/1 - {*8652/0042*} {*AI95-00130-01*} Generic instances are logically expanded at the point of instantiation;

8.5/1 - {*8652/0042*} {*AI95-00130-01*} If an object of a type is declared or allocated and not explicitly initialized, then all expressions appearing in the definition for the type and any of its ancestors are presumed to be used;

8.6/1 - {*8652/0042*} {*AI95-00130-01*} A default_expression for a formal parameter or a generic formal object is considered to be used if and only if the corresponding actual parameter is not provided in a given call or instantiation.

Implementation Permissions

8.7/3 {*AI05-0269-1*} An implementation may provide implementation-defined restrictions; the identifier for an implementation-defined restriction shall differ from those of the language-defined restrictions.

8.a.2/3 **Implementation defined:** Implementation-defined restrictions allowed in a pragma Restrictions.

9 An implementation may place limitations on the values of the expression that are supported, and limitations on the supported combinations of restrictions. The consequences of violating such limitations are implementation defined.

9.a **Implementation defined:** The consequences of violating limitations on Restrictions pragmas.

9.b **Ramification:** Such limitations may be enforced at compile time or at run time. Alternatively, the implementation is allowed to declare violations of the restrictions to be erroneous, and not enforce them at all.

9.1/1 {*8652/0042*} {*AI95-00130-01*} An implementation is permitted to omit restriction checks for code that is recognized at compile time to be unreachable and for which no code is generated.

9.2/1 {*8652/0043*} {*AI95-00190-01*} Whenever enforcement of a restriction is not required prior to execution, an implementation may nevertheless enforce the restriction prior to execution of a partition to which the restriction applies, provided that every execution of the partition would violate the restriction.

Syntax

10/3 {*AI95-00249-01*} {*AI05-0246-1*} The form of a pragma Profile is as follows:

11/3 **pragma** Profile (*profile*_identifier {, *profile*_pragma_argument_association});

Legality Rules

12/3 {*AI95-00249-01*} {*AI05-0246-1*} The *profile*_identifier shall be the name of a usage profile. The semantics of any *profile*_pragma_argument_associations are defined by the usage profile specified by the *profile*_identifier.

Static Semantics

{*AI95-00249-01*} {*AI05-0246-1*} A profile is equivalent to the set of configuration pragmas that is defined for each usage profile. 13/3

Post-Compilation Rules

{*AI95-00249-01*} A pragma Profile is a configuration pragma. There may be more than one pragma Profile for a partition. 14/3

Implementation Permissions

{*AI05-0269-1*} An implementation may provide implementation-defined usage profiles; the identifier for an implementation-defined usage profile shall differ from those of the language-defined usage profiles. 15/3

Implementation defined: Implementation-defined usage profiles allowed in a pragma Profile. 15.a.1/3

NOTE 1 {*AI95-00347-01*} Restrictions intended to facilitate the construction of efficient tasking run-time systems are defined in D.7. Restrictions intended for use when constructing high integrity systems are defined in H.4. 16/2

NOTE 2 An implementation has to enforce the restrictions in cases where enforcement is required, even if it chooses not to take advantage of the restrictions in terms of efficiency. 17

Discussion: It is not the intent that an implementation will support a different run-time system for every possible combination of restrictions. An implementation might support only two run-time systems, and document a set of restrictions that is sufficient to allow use of the more efficient and safe one. 17.a

Extensions to Ada 83

Pragma Restrictions is new to Ada 95. 17.b

Extensions to Ada 95

{*AI95-00249-01*} {*AI05-0246-1*} Pragma Profile is new; it was moved here by Ada 2012 and renamed to a "usage profile" but was otherwise unchanged. 17.c/3

Wording Changes from Ada 95

{*8652/0042*} {*AI95-00130-01*} **Corrigendum:** Corrected the wording so that restrictions are checked inside of generic instantiations and in default expressions. Since not making these checks would violate the purpose of restrictions, we are not documenting this as an incompatibility. 17.d/2

{*8652/0043*} {*AI95-00190-01*} **Corrigendum:** Added a permission that restrictions can be enforced at compile-time. While this is technically incompatible, documenting it as such would be unnecessarily alarming - there should not be any programs depending on the runtime failure of restrictions. 17.e/2

{*AI95-00381-01*} The syntax of a restriction_parameter_argument has been defined to better support restriction No_Dependence (see 13.12.1). 17.f/2

Wording Changes from Ada 2005

{*AI05-0013-1*} **Correction**: When restrictions are checked has been clarified. 17.g/3

13.12.1 Language-Defined Restrictions and Profiles

Static Semantics

{*AI95-00257-01*} The following *restriction*_identifiers are language defined (additional restrictions are defined in the Specialized Needs Annexes): 1/2

{*AI05-0241-1*} No_Implementation_Aspect_Specifications 1.1/3

There are no implementation-defined aspects specified by an aspect_specification. This restriction applies only to the current compilation or environment, not the entire partition.

Discussion: {*AI05-0241-1*} This restriction (as well as others below) applies only to the current compilation, because it is likely that the runtime (and possibly user-written low-level code) will need to use implementation-defined aspects. But a partition-wide restriction applies everywhere, including the runtime. 1.a/3

2/2 {*AI95-00257-01*} No_Implementation_Attributes

There are no implementation-defined attributes. This restriction applies only to the current compilation or environment, not the entire partition.

2.1/3 {*AI05-0246-1*} {*AI05-0269-1*} No_Implementation_Identifiers

There are no usage names that denote declarations with implementation-defined identifiers that occur within language-defined packages or instances of language-defined generic packages. Such identifiers can arise as follows:

2.2/3 - The following language-defined packages and generic packages allow implementation-defined identifiers:

2.3/3 - package System (see 13.7);

2.4/3 - package Standard (see A.1);

2.5/3 - package Ada.Command_Line (see A.15);

2.6/3 - package Interfaces.C (see B.3);

2.7/3 - package Interfaces.C.Strings (see B.3.1);

2.8/3 - package Interfaces.C.Pointers (see B.3.2);

2.9/3 - package Interfaces.COBOL (see B.4);

2.10/3 - package Interfaces.Fortran (see B.5);

2.11/3 - The following language-defined packages contain only implementation-defined identifiers:

2.12/3 - package System.Machine_Code (see 13.8);

2.13/3 - package Ada.Directories.Information (see A.16);

2.14/3 - nested Implementation packages of the Queue containers (see A.18.28-31);

2.15/3 - package Interfaces (see B.2);

2.16/3 - package Ada.Interrupts.Names (see C.3.2).

2.17/3 For package Standard, Standard.Long_Integer and Standard.Long_Float are considered language-defined identifiers, but identifiers such as Standard.Short_Short_Integer are considered implementation-defined.

2.18/3 This restriction applies only to the current compilation or environment, not the entire partition.

3/2 {*AI95-00257-01*} No_Implementation_Pragmas

There are no implementation-defined pragmas or pragma arguments. This restriction applies only to the current compilation or environment, not the entire partition.

3.1/3 {*AI05-0242-1*} No_Implementation_Units

There is no mention in the context_clause of any implementation-defined descendants of packages Ada, Interfaces, or System. This restriction applies only to the current compilation or environment, not the entire partition.

4/3 {*AI95-00368-01*} {*AI05-0229-1*} No_Obsolescent_Features

There is no use of language features defined in Annex J. It is implementation defined whether uses of the renamings of J.1 and of the pragmas of J.15 are detected by this restriction. This restriction applies only to the current compilation or environment, not the entire partition.

4.a/2 **Reason:** A user could compile a rename like

4.b/2
```
with Ada.Text_IO;
package Text_IO renames Ada.Text_IO;
```

Such a rename must not be disallowed by this restriction, nor should the compilation of such a rename be restricted by an implementation. Many implementations implement the renames of J.1 by compiling them normally; we do not want to require implementations to use a special mechanism to implement these renames. 4.c/2

{*AI05-0229-1*} The pragmas have the same functionality as the corresponding aspect (unlike the typical obsolescent feature), and rejecting them could be a significant portability problem for existing code. 4.d/3

{*AI95-00381-01*} {*AI05-0241-1*} The following *restriction_parameter_*identifiers are language defined: 5/3

{*AI95-00381-01*} No_Dependence 6/2
Specifies a library unit on which there are no semantic dependences.

{*AI05-0241-1*} No_Specification_of_Aspect 6.1/3
Identifies an aspect for which no aspect_specification, attribute_definition_clause, or pragma is given.

{*AI05-0272-1*} No_Use_Of_Attribute 6.2/3
Identifies an attribute for which no attribute_reference or attribute_definition_clause is given.

{*AI05-0272-1*} No_Use_Of_Pragma 6.3/3
Identifies a pragma which is not to be used.

{*AI12-0389-1*} No_Unrecognized_Aspects 6.4/5
There are no aspect_specifications having an unrecognized *aspect_*identifier. This restriction applies only to the current compilation or environment, not the entire partition.

Ramification: When this restriction is in effect, unrecognized aspects cannot be ignored in the current compilation; they violate the restriction. This is true despite the Implementation Permissions of 13.1.1. 6.a/5

{*AI12-0389-1*} No_Unrecognized_Pragmas 6.5/5
There are no pragmas having an unrecognized pragma identifier. This restriction applies only to the current compilation or environment, not the entire partition.

Ramification: When this restriction is in effect, unrecognized pragmas cannot be ignored in the current compilation; they violate the restriction. This is true despite the rules of 2.8. 6.b/5

Legality Rules

{*AI95-00381-01*} {*AI12-0444-1*} The restriction_parameter_argument of a No_Dependence restriction shall be a name; the name shall have the form of a full expanded name of a library unit, but can be a name that has no corresponding unit currently present in the environment. 7/5

Ramification: This name is not resolved. 7.a/2

{*AI05-0241-1*} The restriction_parameter_argument of a No_Specification_of_Aspect restriction shall be an identifier; this is an identifier specific to a pragma (see 2.8) and does not denote any declaration. 7.1/3

Ramification: This restriction_parameter_argument is not resolved as it is an identifier specific to a pragma. As for No_Dependence, there is no check that the aspect identifier is meaningful; it might refer to an implementation-defined aspect on one implementation, but nothing at all on another implementation. 7.b/3

{*AI05-0272-1*} The restriction_parameter_argument of a No_Use_Of_Attribute restriction shall be an identifier or one of the reserved words Access, Delta, Digits, Mod, or Range; this is an identifier specific to a pragma. 7.2/3

Ramification: This restriction_parameter_argument is not resolved as it is an identifier specific to a pragma. There is no check that the attribute identifier refers to a known attribute_designator; it might refer to an implementation-defined attribute on one implementation, but nothing at all on another implementation. 7.c/3

{*AI05-0272-1*} The restriction_parameter_argument of a No_Use_Of_Pragma restriction shall be an identifier or the reserved word Interface; this is an identifier specific to a pragma. 7.3/3

Ramification: This restriction_parameter_argument is not resolved as it is an identifier specific to a pragma. There is no check that the pragma identifier refers to a known pragma; it might refer to an implementation-defined pragma on one implementation, but nothing at all on another implementation. 7.d/3

Post-Compilation Rules

8/3 {*AI95-00381-01*} {*AI05-0241-1*} No compilation unit included in the partition shall depend semantically on the library unit identified by the name of a No_Dependence restriction.

8.a/5 **Ramification:** {*AI12-0005-1*} There is no requirement that the library unit actually exists. One possible use of the pragma is to prevent the use of implementation-defined units; when the program is ported to a different compiler, it is perfectly reasonable that no unit with the name exists.

Static Semantics

9/3 {*AI05-0246-1*} The following *profile*_identifier is language defined:

10/3 {*AI05-0246-1*} No_Implementation_Extensions

11/3 {*AI05-0246-1*} For usage profile No_Implementation_Extensions, there shall be no *profile*_pragma_argument_associations.

12/3 {*AI05-0246-1*} The No_Implementation_Extensions usage profile is equivalent to the following restrictions:

13/3
```
No_Implementation_Aspect_Specifications,
No_Implementation_Attributes,
No_Implementation_Identifiers,
No_Implementation_Pragmas,
No_Implementation_Units.
```

Extensions to Ada 95

13.a/2 {*AI95-00257-01*} {*AI95-00368-01*} Restrictions No_Implementation_Attributes, No_Implementation_Pragmas, and No_Obsolescent_Features are new.

13.b/2 {*AI95-00381-01*} Restriction No_Dependence is new.

Extensions to Ada 2005

13.c/3 {*AI05-0241-1*} {*AI05-0242-1*} {*AI05-0246-1*} {*AI05-0272-1*} Restrictions No_Implementation_Aspect_Specifications, No_Implementation_Identifiers, No_Implementation_Units, No_Specification_of_Aspect, No_Use_of_Attribute, and No_Use_of_Pragma are new.

13.d/3 {*AI05-0246-1*} Profile No_Implementation_Extensions is new.

Extensions to Ada 2012

13.e/5 {*AI12-0389-1*} Restrictions No_Unrecognized_Aspects and No_Unrecognized_Pragmas are new.

13.13 Streams

1 A *stream* is a sequence of elements comprising values from possibly different types and allowing sequential access to these values. A *stream type* is a type in the class whose root type is Streams.Root_Stream_Type. A stream type may be implemented in various ways, such as an external sequential file, an internal buffer, or a network channel.

1.a **Discussion:** A stream element will often be the same size as a storage element, but that is not required.

1.b/5 **Term entry: stream** — sequence of elements that can be used, along with the stream-oriented attributes, to support marshalling and unmarshalling of values of most types

Extensions to Ada 83

1.c Streams are new in Ada 95.

13.13.1 The Streams Subsystem

Static Semantics

The abstract type Root_Stream_Type is the root type of the class of stream types. The types in this class represent different kinds of streams. A new stream type is defined by extending the root type (or some other stream type), overriding the Read and Write operations, and optionally defining additional primitive subprograms, according to the requirements of the particular kind of stream. The predefined stream-oriented attributes like T'Read and T'Write make dispatching calls on the Read and Write procedures of the Root_Stream_Type. (User-defined T'Read and T'Write attributes can also make such calls, or can call the Read and Write attributes of other types.) 1

{*AI12-0293-1*} The library package Ada.Streams has the following declaration: 1.1/5

```
{AI12-0241-1} package Ada.Streams                                                    2/5
    with Pure, Nonblocking => False is

{AI95-00161-01}     type Root_Stream_Type is abstract tagged limited private         3/2
        with Preelaborable_Initialization;

{8652/0044} {AI95-00181-01}     type Stream_Element is mod implementation-defined;   4/1
    type Stream_Element_Offset is range implementation-defined;
    subtype Stream_Element_Count is
        Stream_Element_Offset range 0..Stream_Element_Offset'Last;
    type Stream_Element_Array is
        array(Stream_Element_Offset range <>) of aliased Stream_Element;

    procedure Read(                                                                  5
      Stream : in out Root_Stream_Type;
      Item   : out Stream_Element_Array;
      Last   : out Stream_Element_Offset) is abstract;

    procedure Write(                                                                 6
      Stream : in out Root_Stream_Type;
      Item   : in Stream_Element_Array) is abstract;

private                                                                              7
   ... -- not specified by the language
end Ada.Streams;
```

Reason: {*AI12-0241-1*} This package must allow blocking (Nonblocking => False) for compatibility. The purpose of this package is to provide a template for overriding user-defined routines; and such routines can only allow blocking if the root type does so. Users can still declare their overridding routines nonblocking if they wish. 7.a/5

{*AI95-00227-01*} The Read operation transfers stream elements from the specified stream to fill the array Item. Elements are transferred until Item'Length elements have been transferred, or until the end of the stream is reached. If any elements are transferred, the index of the last stream element transferred is returned in Last. Otherwise, Item'First - 1 is returned in Last. Last is less than Item'Last only if the end of the stream is reached. 8/2

The Write operation appends Item to the specified stream. 9

Discussion: {*AI95-00114-01*} The index subtype of Stream_Element_Array is Stream_Element_Offset because we wish to allow maximum flexibility. Most Stream_Element_Arrays will probably have a lower bound of 0 or 1, but other lower bounds, including negative ones, make sense in some situations. 9.a/2

{*AI95-00114-01*} {*AI05-0005-1*} Note that there are some language-defined subprograms that fill part of a Stream_Element_Array, and return the index of the last element filled as a Stream_Element_Offset. The Read procedures declared here, Streams.Stream_IO (see A.12.1), and System.RPC (see E.5) behave in this manner. These will raise Constraint_Error if the resulting Last value is not in Stream_Element_Offset. This implies that the Stream_Element_Array passed to these subprograms should not have a lower bound of Stream_Element_Offset'First, because then a read of 0 elements would always raise Constraint_Error. A better choice of lower bound is 0 or 1. 9.b/3

{*AI12-0293-1*} Three additional packages provide stream implementations that do not make use of any file operations. These packages provide the same operations, with Streams.Storage providing an abstract 10/5

interface, and two child packages providing implementations of that interface. The difference is that for Streams.Storage.Bounded, the maximum storage is bounded.

11/5 {*AI12-0293-1*} The library package Ada.Streams.Storage has the following declaration:

12/5
```
package Ada.Streams.Storage
   with Pure, Nonblocking is

13/5  type Storage_Stream_Type is abstract new Root_Stream_Type with private;

14/5  function Element_Count (Stream : Storage_Stream_Type)
         return Stream_Element_Count is abstract;

15/5  procedure Clear (Stream : in out Storage_Stream_Type) is abstract;

16/5 private
   ... -- not specified by the language
end Ada.Streams.Storage;
```

17/5 {*AI12-0293-1*} The library package Ada.Streams.Storage.Unbounded has the following declaration:

18/5
```
package Ada.Streams.Storage.Unbounded
   with Prelaborated, Nonblocking, Global => in out synchronized is

19/5  type Stream_Type is new Storage_Stream_Type with private
         with Default_Initial_Condition =>
             Element_Count (Stream_Type) = 0;

20/5  overriding
      procedure Read (
         Stream : in out Stream_Type;
         Item   : out Stream_Element_Array;
         Last   : out Stream_Element_Offset)
         with Post =>
             (declare
                 Num_Read : constant Stream_Element_Count :=
                    Stream_Element_Count'Min
                       (Element_Count(Stream)'Old, Item'Length);
              begin
                 Last = Num_Read + Item'First - 1 and
                 Element_Count (Stream) =
                    Element_Count (Stream)'Old - Num_Read);
```

20.a/5 **Discussion:** Num_Read is the number of elements read; this is the minimum of Item'Length and the number of available elements. Last then is determined by that, and the Element_Count decreases by the number of elements read.

21/5
```
      overriding
      procedure Write (
         Stream : in out Stream_Type;
         Item   : in Stream_Element_Array)
         with Post =>
            Element_Count (Stream) =
            Element_Count (Stream)'Old + Item'Length;

22/5  overriding
      function Element_Count (Stream : Stream_Type)
         return Stream_Element_Count;

23/5  overriding
      procedure Clear (Stream : in out Stream_Type)
         with Post => Element_Count (Stream) = 0;

24/5 private
   ... -- not specified by the language
end Ada.Streams.Storage.Unbounded;
```

25/5 {*AI12-0293-1*} The library package Ada.Streams.Storage.Bounded has the following declaration:

26/5
```
package Ada.Streams.Storage.Bounded
    with Pure, Nonblocking is

27/5  type Stream_Type (Max_Elements : Stream_Element_Count)
         is new Storage_Stream_Type with private
         with Default_Initial_Condition =>
            Element_Count (Stream_Type) = 0;
```

```
   overriding                                                                    28/5
   procedure Read (
      Stream : in out Stream_Type;
      Item   : out Stream_Element_Array;
      Last   : out Stream_Element_Offset)
      with Post =>
          (declare
              Num_Read : constant Stream_Element_Count :=
                 Stream_Element_Count'Min
                    (Element_Count(Stream)'Old, Item'Length);
           begin
              Last = Num_Read + Item'First - 1 and
              Element_Count (Stream) =
                 Element_Count (Stream)'Old - Num_Read);

   overriding                                                                    29/5
   procedure Write (
      Stream : in out Stream_Type;
      Item   : in Stream_Element_Array)
      with Pre =>
              Element_Count (Stream) + Item'Length <= Stream.Max_Elements
              or else (raise Constraint_Error),
           Post =>
              Element_Count (Stream) =
              Element_Count (Stream)'Old + Item'Length;

   overriding                                                                    30/5
   function Element_Count (Stream : Stream_Type)
      return Stream_Element_Count
      with Post => Element_Count'Result <= Stream.Max_Elements;

   overriding                                                                    31/5
    procedure Clear (Stream : in out Stream_Type)
       with Post => Element_Count (Stream) = 0;

private                                                                          32/5
   ... -- not specified by the language
end Ada.Streams.Storage.Bounded;
```

{*AI12-0293-1*} The Element_Count functions return the number of stream elements that are available for reading from the given stream. 33/5

{*AI12-0293-1*} The Read and Write procedures behave as described for package Ada.Streams above. Stream elements are read in FIFO (first-in, first-out) order; stream elements are available for reading immediately after they are written. 34/5

{*AI12-0293-1*} The Clear procedures remove any available stream elements from the given stream. 35/5

Implementation Permissions

{*8652/0044*} {*AI95-00181-01*} {*AI12-0444-1*} If Stream_Element'Size is not a multiple of System.Storage_Unit, then the components of Stream_Element_Array will not be aliased. 36/5

Ramification: {*AI95-00114-01*} If the Stream_Element'Size is less than the size of System.Storage_Unit, then components of Stream_Element_Array need not be aliased. This is necessary as the components of type Stream_Element size might not be addressable on the target architecture. 36.a/2

Implementation Advice

{*AI12-0293-1*} Streams.Storage.Bounded.Stream_Type objects should be implemented without implicit pointers or dynamic allocation. 37/5

Implementation Advice: Streams.Storage.Bounded.Stream_Type objects should be implemented without implicit pointers or dynamic allocation. 37.a.1/5

Reason: The Streams.Storage.Bounded package is provided in order to make available an alternative to the Streams.Storage.Unbounded package which gives more predictable memory usage. 37.a/5

NOTE 1 See A.12.1, “The Package Streams.Stream_IO” for an example of extending type Root_Stream_Type. 38

39/2 NOTE 2 {*AI95-00227-01*} If the end of stream has been reached, and Item'First is Stream_Element_Offset'First, Read will raise Constraint_Error.

39.a/2 **Ramification:** Thus, Stream_Element_Arrays should start at 0 or 1, not Stream_Element_Offset'First.

Extensions to Ada 95

39.b/2 {*AI95-00161-01*} **Amendment Correction:** Added pragma Preelaborable_Initialization to type Root_Stream_Type.

Wording Changes from Ada 95

39.c/2 {*8652/0044*} {*AI95-00181-01*} **Corrigendum:** Stream elements are aliased presuming that makes sense.

39.d/2 {*AI95-00227-01*} Fixed the wording for Read to properly define the result in Last when no stream elements are transfered.

Extensions to Ada 2012

39.e/5 {*AI12-0293-1*} Package Ada.Streams.Storage and its children are new.

13.13.2 Stream-Oriented Attributes

1/3 {*8652/0009*} {*AI95-00137-01*} {*AI05-0183-1*} The type-related operational attributes Write, Read, Output, and Input convert values to a stream of elements and reconstruct values from a stream.

Static Semantics

1.1/2 {*AI95-00270-01*} For every subtype S of an elementary type *T*, the following representation attribute is defined:

1.2/3 S'Stream_Size

{*AI95-00270-01*} {*AI05-0194-1*} Denotes the number of bits read from or written to a stream by the default implementations of S'Read and S'Write. Hence, the number of stream elements required per item of elementary type *T* is:

1.3/2
```
T'Stream_Size / Ada.Streams.Stream_Element'Size
```

1.4/2 The value of this attribute is of type *universal_integer* and is a multiple of Stream_Element'Size.

1.5/2 Stream_Size may be specified for first subtypes via an attribute_definition_clause; the expression of such a clause shall be static, nonnegative, and a multiple of Stream_Element'Size.

1.a/3 **Aspect Description for Stream_Size:** Size in bits used to represent elementary objects in a stream.

1.b/2 **Discussion:** Stream_Size is a type-related attribute (see 13.1).

1.c/3 **Ramification:** {*AI05-0194-1*} The value of S'Stream_Size is unaffected by the presence or absence of any attribute_definition_clauses or aspect_specifications specifying the Read or Write attributes of any ancestor of S. S'Stream_Size is defined in terms of the behavior of the default implementations of S'Read and S'Write even if those default implementations are overridden.

Implementation Advice

1.6/2 {*AI95-00270-01*} If not specified, the value of Stream_Size for an elementary type should be the number of bits that corresponds to the minimum number of stream elements required by the first subtype of the type, rounded up to the nearest factor or multiple of the word size that is also a multiple of the stream element size.

1.d/2 **Implementation Advice:** If not specified, the value of Stream_Size for an elementary type should be the number of bits that corresponds to the minimum number of stream elements required by the first subtype of the type, rounded up to the nearest factor or multiple of the word size that is also a multiple of the stream element size.

1.e/2 **Reason:** {*AI95-00270-01*} This is Implementation Advice because we want to allow implementations to remain compatible with their Ada 95 implementations, which may have a different handling of the number of stream elements. Users can always specify Stream_Size if they need a specific number of stream elements.

{*AI95-00270-01*} The recommended level of support for the Stream_Size attribute is: 1.7/2

- {*AI95-00270-01*} A Stream_Size clause should be supported for a discrete or fixed point type *T* if the specified Stream_Size is a multiple of Stream_Element'Size and is no less than the size of the first subtype of *T*, and no greater than the size of the largest type of the same elementary class (signed integer, modular integer, enumeration, ordinary fixed point, or decimal fixed point). 1.8/2

  Implementation Advice: The recommended level of support for the Stream_Size attribute should be followed. 1.f/2

  Ramification: There are no requirements beyond supporting confirming Stream_Size clauses for floating point and access types. Floating point and access types usually only have a handful of defined formats, streaming anything else makes no sense for them. 1.g/2

  For discrete and fixed point types, this may require support for sizes other than the “natural” ones. For instance, on a typical machine with 32-bit integers and a Stream_Element'Size of 8, setting Stream_Size to 24 must be supported. This is required as such formats can be useful for interoperability with unusual machines, and there is no difficulty with the implementation (drop extra bits on output, sign extend on input). 1.h/2

Static Semantics

For every subtype S of a specific type *T*, the following attributes are defined. 2

S'Write S'Write denotes a procedure with the following specification: 3

```
{AI95-00441-01} procedure S'Write(
   Stream : not null access Ada.Streams.Root_Stream_Type'Class;
   Item : in T)
```
4/2

S'Write writes the value of *Item* to *Stream*. 5

S'Read S'Read denotes a procedure with the following specification: 6

```
{AI95-00441-01} procedure S'Read(
   Stream : not null access Ada.Streams.Root_Stream_Type'Class;
   Item : out T)
```
7/2

S'Read reads the value of *Item* from *Stream*. 8

This paragraph was deleted.{*8652/0040*} {*AI95-00108-01*} {*AI95-00444-01*} {*AI05-0192-1*} {*AI12-0419-1*} 8.1/5

{*AI95-00444-01*} The default implementations of the Write and Read attributes, where available, execute as follows: 8.2/2

{*8652/0040*} {*AI95-00108-01*} {*AI95-00195-01*} {*AI95-00251-01*} {*AI95-00270-01*} {*AI05-0139-2*} {*AI12-0191-1*} {*AI12-0419-1*} For nonderived elementary types, Read reads (and Write writes) the number of stream elements implied by the Stream_Size for the type *T*; the representation of those stream elements is implementation defined. For nonderived composite types, the Write or Read attribute for each component (excluding those, if any, that are not components of the nominal type of the object) is called in canonical order, which is last dimension varying fastest for an array (unless the convention of the array is Fortran, in which case it is first dimension varying fastest), and positional aggregate order for a record. Bounds are not included in the stream if *T* is an array type. If *T* is a discriminated type, discriminants are included only if they have defaults. If *T* is a tagged type, the tag is not included. 9/5

Implementation defined: The contents of the stream elements read and written by the Read and Write attributes of elementary types. 9.a/2

{*AI12-0419-1*} For type extensions, the Write or Read attribute for the parent type is called, followed by the Write or Read attribute of each component of the extension part, in canonical order. For a limited type extension, if the attribute of the parent type or any progenitor type of *T* is available anywhere within the immediate scope of *T*, and the attribute of the parent type or the type of any of the extension components is not available at the freezing point of *T*, then the attribute of *T* shall be directly specified. For untagged derived types, the Write (resp. Read) attribute invokes the corresponding attribute of the parent type, if the attribute is available for the parent type. 9.1/5

9.a.1/5 **Implementation Note:** {*AI12-0419-1*} The default implementation of a stream-oriented attribute might not be well-defined in cases where the attribute is never available anywhere in the scope of the type. In such cases, the attribute cannot be called and is defined (far below) to raise Program_Error.

9.2/5 {*AI05-0023-1*} {*AI05-0264-1*} {*AI12-0419-1*} If *T* is a discriminated type and its discriminants have defaults, then S'Read first reads the discriminants from the stream without modifying *Item*. S'Read then creates an object of type *T* constrained by these discriminants. The value of this object is then converted to the subtype of *Item* and is assigned to *Item*. Finally, the Read attribute for each nondiscriminant component of *Item* is called in canonical order as described above. Normal default initialization and finalization take place for the created object.

9.b **Reason:** A discriminant with a default value is treated simply as a component of the object. On the other hand, an array bound or a discriminant without a default value, is treated as "descriptor" or "dope" that must be provided in order to create the object and thus is logically separate from the regular components. Such "descriptor" data are written by 'Output and produced as part of the delivered result by the 'Input function, but they are not written by 'Write nor read by 'Read. A tag is like a discriminant without a default.

9.b.1/1 {*8652/0040*} {*AI95-00108-01*} For limited type extensions, we must have a definition of 'Read and 'Write if the parent type has one, as it is possible to make a dispatching call through the attributes. The rule is designed to automatically do the right thing in as many cases as possible.

9.b.2/1 {*AI95-00251-01*} Similarly, a type that has a progenitor with an available attribute must also have that attribute, for the same reason.

9.b.3/3 {*AI05-0023-1*} The semantics of S'Read for a discriminated type with defaults involves an anonymous object so that the point of required initialization and finalization is well-defined, especially for objects that change shape and have controlled components. The creation of this anonymous object often can be omitted (see the Implementation Permissions below).

9.c/2 **Ramification:** {*AI95-00195-01*} For a composite object, the subprogram denoted by the Write or Read attribute of each component is called, whether it is the default or is user-specified. Implementations are allowed to optimize these calls (see below), presuming the properties of the attributes are preserved.

9.3/5 {*AI95-00270-01*} {*AI05-0264-1*} {*AI12-0419-1*} Constraint_Error is raised by the predefined Write attribute if the value of the elementary item is outside the range of values representable using Stream_Size bits. For a signed integer type, an enumeration type, or a fixed point type, the range is unsigned only if the integer code for the lower bound of the first subtype is nonnegative, and a (symmetric) signed range that covers all values of the first subtype would require more than Stream_Size bits; otherwise, the range is signed.

10 For every subtype S'Class of a class-wide type *T*'Class:

11 S'Class'Write

S'Class'Write denotes a procedure with the following specification:

12/2
```
{AI95-00441-01} procedure S'Class'Write(
   Stream : not null access Ada.Streams.Root_Stream_Type'Class;
   Item   : in T'Class)
```

13 Dispatches to the subprogram denoted by the Write attribute of the specific type identified by the tag of Item.

14 S'Class'Read

S'Class'Read denotes a procedure with the following specification:

15/2
```
{AI95-00441-01} procedure S'Class'Read(
   Stream : not null access Ada.Streams.Root_Stream_Type'Class;
   Item : out T'Class)
```

16 Dispatches to the subprogram denoted by the Read attribute of the specific type identified by the tag of Item.

16.a **Reason:** It is necessary to have class-wide versions of Read and Write in order to avoid generic contract model violations; in a generic, we don't necessarily know at compile time whether a given type is specific or class-wide.

Paragraph 17 was deleted.

Static Semantics

For every subtype S of a specific type *T*, the following attributes are defined. 18

S'Output S'Output denotes a procedure with the following specification: 19

```
{AI95-00441-01} procedure S'Output(                                          20/2
   Stream : not null access Ada.Streams.Root_Stream_Type'Class;
   Item : in T)
```

S'Output writes the value of *Item* to *Stream*, including any bounds or discriminants. 21

Ramification: Note that the bounds are included even for an array type whose first subtype is constrained. 21.a

S'Input S'Input denotes a function with the following specification: 22

```
{AI95-00441-01} function S'Input(                                            23/2
   Stream : not null access Ada.Streams.Root_Stream_Type'Class)
   return T
```

S'Input reads and returns one value from *Stream*, using any bounds or discriminants written by a corresponding S'Output to determine how much to read. 24

{*8652/0040*} {*AI95-00108-01*} {*AI95-00444-01*} {*AI05-0192-1*} {*AI12-0419-1*} For an untagged derived type, the default implementation of the Output (resp. Input) attribute invokes the corresponding attribute of the parent type, if the attribute is available for the parent type. For any other type, the default implementations of the Output and Input attributes, where available, execute as follows: 25/5

- {*AI05-0269-1*} If *T* is an array type, S'Output first writes the bounds, and S'Input first reads the bounds. If *T* has discriminants without defaults, S'Output first writes the discriminants (using the Write attribute of the discriminant type for each), and S'Input first reads the discriminants (using the Read attribute of the discriminant type for each). 26/3
- {*AI95-00195-01*} {*AI05-0023-1*} S'Output then calls S'Write to write the value of *Item* to the stream. S'Input then creates an object of type *T*, with the bounds or (when without defaults) the discriminants, if any, taken from the stream, passes it to S'Read, and returns the value of the object. If *T* has discriminants, then this object is unconstrained if and only the discriminants have defaults. Normal default initialization and finalization take place for this object (see 3.3.1, 7.6, and 7.6.1). 27/3

{*AI95-00251-01*} If *T* is an abstract type, then S'Input is an abstract function. 27.1/2

Ramification: For an abstract type *T*, S'Input can be called in a dispatching call, or passed to an abstract formal subprogram. But it cannot be used in nondispatching contexts, because we don't allow objects of abstract types to exist. The designation of this function as abstract has no impact on descendants of *T*, as *T*'Input is not inherited for tagged types, but rather recreated (and the default implementation of *T*'Input calls *T*'Read, not the parent type's *T*'Input). Note that *T*'Input cannot be specified in this case, as any function with the proper profile is necessarily abstract, and specifying abstract subprograms in an attribute_definition_clause is illegal. 27.a/2

For every subtype S'Class of a class-wide type *T*'Class: 28

S'Class'Output 29

S'Class'Output denotes a procedure with the following specification:

```
{AI95-00441-01} procedure S'Class'Output(                                    30/2
   Stream : not null access Ada.Streams.Root_Stream_Type'Class;
   Item   : in T'Class)
```

{*AI95-00344-01*} First writes the external tag of *Item* to *Stream* (by calling String'Output(*Stream*, Tags.External_Tag(*Item*'Tag)) — see 3.9) and then dispatches to the subprogram denoted by the Output attribute of the specific type identified by the tag. Tag_Error is raised if the tag of Item identifies a type declared at an accessibility level deeper than that of S. 31/2

Reason: {*AI95-00344-01*} We raise Tag_Error here for nested types as such a type cannot be successfully read with S'Class'Input, and it doesn't make sense to allow writing a value that cannot be read. 31.a/2

32 S'Class'Input

S'Class'Input denotes a function with the following specification:

33/2
```
{AI95-00441-01} function S'Class'Input(
   Stream : not null access Ada.Streams.Root_Stream_Type'Class)
   return T'Class
```

34/5 {*AI95-00279-01*} {*AI95-00344-01*} {*AI05-0109-1*} {*AI12-0439-1*} First reads the external tag from *Stream* and determines the corresponding internal tag (by calling Tags.Descendant_Tag(String'Input(*Stream*), S'Tag) which can raise Tag_Error — see 3.9) and then dispatches to the subprogram denoted by the Input attribute of the specific type identified by the internal tag; returns that result. If the specific type identified by the internal tag is abstract, Constraint_Error is raised.

34.a/3 **Ramification:** {*AI05-0109-1*} Descendant_Tag will ensure that the tag it returns is covered by T'Class; Tag_Error will be raised if it would not cover T'Class.

35/3 {*AI95-00195-01*} {*AI05-0228-1*} In the default implementation of Read and Input for a composite type, for each scalar component that is a discriminant or that has an implicit initial value, a check is made that the value returned by Read for the component belongs to its subtype. Constraint_Error is raised if this check fails. For other scalar components, no check is made. For each component that is of an access type, if the implementation can detect that the value returned by Read for the component is not a value of its subtype, Constraint_Error is raised. If the value is not a value of its subtype and this error is not detected, the component has an abnormal value, and erroneous execution can result (see 13.9.1). In the default implementation of Read for a composite type with defaulted discriminants, if the actual parameter of Read is constrained, a check is made that the discriminants read from the stream are equal to those of the actual parameter. Constraint_Error is raised if this check fails.

35.a/3 **Reason:** {*AI05-0228-1*} The check for scalar components that have an implicit initial value is to preserve our Language Design Principle that all objects that have an implicit initial value do not become "deinitialized".

35.b/3 **Ramification:** {*AI05-0228-1*} A scalar component can have an implicit initial value if it has a default_expression, if the component's type has the Default_Value aspect specified, or if the component is that of an array type that has the Default_Component_Value aspect specified.

35.c/3 **To be honest:** {*AI05-0228-1*} An implementation should always be able to detect the error for a null value read into a component of an access subtype with a null exclusion; the "if the implementation can detect" is intended to cover nonnull access values.

36/2 {*AI95-00195-01*} It is unspecified at which point and in which order these checks are performed. In particular, if Constraint_Error is raised due to the failure of one of these checks, it is unspecified how many stream elements have been read from the stream.

37/1 {*8652/0045*} {*AI95-00132-01*} In the default implementation of Read and Input for a type, End_Error is raised if the end of the stream is reached before the reading of a value of the type is completed.

37.1/5 {*AI12-0064-2*} {*AI12-0396-1*} The Nonblocking aspect is statically True and the Global aspect is **null** for the default implementations of stream-oriented attributes for elementary types. For the default implementations of stream-oriented attributes for composite types, the value of the Nonblocking aspect is that of the first subtype, and the Global aspect defaults to that of the first subtype. A default implementation of a stream-oriented attribute that has the Nonblocking aspect statically True is considered a nonblocking region. The aspect Dispatching (see H.7.1) is Read(Stream) for the default implementations of the stream-oriented attributes Read, Read'Class, Input, and Input'Class; the aspect Dispatching is Write(Stream) for the default implementations of the stream-oriented attributes Write, Write'Class, Output, and Output'Class.

37.a/5 **Ramification:** If the default implementation of a stream-oriented attribute *A* for a composite type would call other stream-oriented attribute(s) whose Global aspect was not allowed by the Global aspect of*A*, then the Legality Rules of 6.1.2 are violated and the type declaration is illegal. If the stream-oriented attribute *A* is overridden, then the default implementation is not created and this check is not made. A similar ramification applies to the Nonblocking aspect of default implementation of a stream-oriented attribute.

{*8652/0040*} {*AI95-00108-01*} {*AI95-00195-01*} {*AI95-00251-01*} {*AI05-0039-1*} {*AI12-0106-1*} {*AI12-0121-1*} {*AI12-0435-1*} The stream-oriented attributes may be specified for any type via an attribute_definition_clause. [Alternatively, each of the specific stream-oriented attributes may be specified using an aspect_specification on any type_declaration, with the aspect name being the corresponding attribute name.] Each of the class-wide stream-oriented attributes may be specified using an aspect_specification for a tagged type *T* using the name of the stream-oriented attribute followed by 'Class; such class-wide aspects do not apply to other descendants of *T*. If not directly specified, a default implementation of a stream-oriented attribute is implicitly composed for a nonlimited type, and for certain limited types, as defined above. 38/5

Reason: {*AI95-00195-01*} {*AI12-0106-1*} We need the last sentence to override the blanket rule given in 13.1.1 that aspect'Class applies to the type and all descendants. 38.a/4

This paragraph was deleted.{*8652/0040*} {*AI95-00108-01*} {*AI95-00195-01*} 38.a.1/2

Proof: {*AI12-0121-1*} 13.1.1 says that all operational attributes can be specified with an aspect_specification. 38.a.2/4

Aspect Description for Read'Class: Procedure to read a value from a stream for the class-wide type associated with a given type. 38.a.3/4

Aspect Description for Write'Class: Procedure to write a value to a stream for a the class-wide type associated with a given type. 38.a.4/4

Aspect Description for Input'Class: Function to read a value from a stream for a the class-wide type associated with a given type, including any bounds and discriminants. 38.a.5/4

Aspect Description for Output'Class: Procedure to write a value to a stream for a the class-wide type associated with a given type, including any bounds and discriminants. 38.a.6/4

{*AI12-0121-1*} The subprogram name given in such an attribute_definition_clause or aspect_specification shall statically denote a subprogram that is not an abstract subprogram. Furthermore, if a specific stream-oriented attribute is specified for an interface type, the subprogram name given in the attribute_definition_clause or aspect_specification shall statically denote a null procedure. 38.1/4

Discussion: {*AI95-00251-01*} Stream attributes (other than Input) are always null procedures for interface types (they have no components). We need to allow explicit setting of the Read and Write attributes in order that the class-wide attributes like LI'Class'Input can be made available. (In that case, any descendant of the interface type would require available attributes.) But we don't allow any concrete implementation because these don't participate in extensions (unless the interface is the parent type). If we didn't ban concrete implementations, the order of declaration of a pair of interfaces would become significant. For example, if Int1 and Int2 are interfaces with concrete implementations of 'Read, then the following declarations would have different implementations for 'Read: 38.b/2

```
type Con1 is new Int1 and Int2 with null record;
type Con2 is new Int2 and Int1 with null record;
```
38.c/2

This would violate our design principle that the order of the specification of the interfaces in a derived_type_definition doesn't matter. 38.d/2

Ramification: The Input attribute cannot be specified for an interface. As it is a function, a null procedure is impossible; a concrete function is not possible anyway as any function returning an abstract type must be abstract. And we don't allow specifying stream attributes to be abstract subprograms. This has no impact, as the availability of Int'Class'Input (where Int is a limited interface) depends on whether Int'Read (not Int'Input) is specified. There is no reason to allow Int'Output to be specified, either, but there is equally no reason to disallow it, so we don't have a special rule for that. 38.e/2

Discussion: {*AI95-00195-01*} Limited types generally do not have default implementations of the stream-oriented attributes. The rules defining when a stream-oriented attribute is available (see below) determine when an attribute of a limited type is in fact well defined and usable. The rules are designed to maximize the number of cases in which the attributes are usable. For instance, when the language provides a default implementation of an attribute for a limited type based on a specified attribute for the parent type, we want to be able to call that attribute. 38.f/2

Aspect Description for Read: Procedure to read a value from a stream for a given type. 38.g/3

Aspect Description for Write: Procedure to write a value to a stream for a given type. 38.h/3

Aspect Description for Input: Function to read a value from a stream for a given type, including any bounds and discriminants. 38.i/3

Aspect Description for Output: Procedure to write a value to a stream for a given type, including any bounds and discriminants. 38.j/3

39/2 {*AI95-00195-01*} A stream-oriented attribute for a subtype of a specific type *T* is *available* at places where one of the following conditions is true:

40/2 • *T* is nonlimited.

41/2 • The attribute_designator is Read (resp. Write) and *T* is a limited record extension, and the attribute Read (resp. Write) is available for the parent type of *T* and for the types of all of the extension components.

41.a/2 **Reason:** In this case, the language provides a well-defined default implementation, which we want to be able to call.

42/5 • {*AI12-0419-1*} *T* is a limited untagged derived type, and the attribute is available for the parent type.

42.a/5 **Reason:** {*AI12-0419-1*} Again, the language provides a default implementation, which we want to be able to call.

43/2 • The attribute_designator is Input (resp. Output), and *T* is a limited type, and the attribute Read (resp. Write) is available for *T*.

43.a/2 **Reason:** The default implementation of Input and Output are based on Read and Write; so if the implementation of Read or Write is good, so is the matching implementation of Input or Output.

44/5 • {*AI12-0419-1*} The attribute has been specified via an attribute_definition_clause or aspect_specification, and the attribute_definition_clause or aspect_specification is visible.

44.a/2 **Reason:** We always want to allow calling a specified attribute. But we don't want availability to break privacy. Therefore, only attributes whose specification can be seen count. Yes, we defined the visibility of an attribute_definition_clause (see 8.3).

45/2 {*AI95-00195-01*} A stream-oriented attribute for a subtype of a class-wide type *T*'Class is available at places where one of the following conditions is true:

46/2 • *T* is nonlimited;

47/5 • {*AI12-0419-1*} the attribute has been specified via an attribute_definition_clause or aspect_specification, and the attribute_definition_clause or aspect_specification is visible; or

48/2 • the corresponding attribute of *T* is available, provided that if *T* has a partial view, the corresponding attribute is available at the end of the visible part where *T* is declared.

48.a/2 **Reason:** The rules are stricter for class-wide attributes because (for the default implementation) we must ensure that any specific attribute that might ever be dispatched to is available. Because we require specification of attributes for extensions of limited parent types with available attributes, we can in fact know this. Otherwise, we would not be able to use default class-wide attributes with limited types, a significant limitation.

49/4 {*AI95-00195-01*} {*AI12-0030-1*} An attribute_reference for one of the stream-oriented attributes is illegal unless the attribute is available at the place of the attribute_reference. Furthermore, an attribute_reference for *T*'Input is illegal if *T* is an abstract type. In addition to the places where Legality Rules normally apply (see 12.3), these rules also apply in the private part of an instance of a generic unit.

49.a/2 **Discussion:** Stream attributes always exist. It is illegal to call them in some cases. Having the attributes not be defined for some limited types would seem to be a cleaner solution, but it would lead to contract model problems for limited private types.

49.b/2 *T*'Input is available for abstract types so that *T*'Class'Input is available. But we certainly don't want to allow calls that could create an object of an abstract type. Remember that *T*'Class is never abstract, so the above legality rule doesn't apply to it. We don't have to discuss whether the attribute is specified, as it cannot be: any function returning the type would have to be abstract, and we do not allow specifying an attribute with an abstract subprogram.

49.c/4 **To be honest:** {*AI12-0030-1*} "These rules apply" refers to just this paragraph and not to the rest of the rules in this section. This rule probably should have been a Legality Rule, but the word "illegal" should key the reader that this is a Legality Rule, no matter under what text heading it occurs.

49.1/5 {*AI12-0030-1*} {*AI12-0419-1*} Unless available for a parent type, if any, for an untagged type having a task, protected, or explicitly limited record part, the default implementation of each of the Read, Write, Input, and Output attributes raises Program_Error and performs no other action.

Discussion: {*AI12-0030-1*} {*AI12-0419-1*} It might seem that there is no need to specify the behavior of the default implementation of a streaming attribute of, for example, a task type because there is no way that it can be invoked. It is possible, however, to construct an example where such a stream attribute can be invoked. This involves using a formal untagged limited derived type for which some streaming attribute is available (because it was explicitly specified for the ancestor type) and a corresponding actual type for which the attribute is unspecified (because the derivation occurred in a place where the attribute is never available for the parent type). 49.d/5

{*AI95-00195-01*} {*AI05-0192-1*} In the parameter_and_result_profiles for the default implementations of the stream-oriented attributes, the subtype of the *Item* parameter is the base subtype of *T* if *T* is a scalar type, and the first subtype otherwise. The same rule applies to the result of the Input attribute. 50/3

{*AI95-00195-01*} {*AI05-0007-1*} {*AI12-0427-1*} For an attribute_definition_clause or aspect_specification specifying one of these attributes, the subtype of the *Item* parameter shall be the first subtype or the base subtype if scalar, and the first subtype if not scalar. The same rule applies to the result of the Input function. 51/5

Reason: This is to simplify implementation. 51.a/2

Ramification: {*AI12-0427-1*} The view of the type at the point of the attribute_definition_clause determines whether the base subtype is allowed. Thus, for a scalar type with a partial view (which is never scalar), whether the base subtype is allowed is determined by whether the attribute_definition_clause occurs before or after the full definition of the scalar type. For the same reason, the base subtype is never allowed for an attribute specified via an aspect_specification on the partial view. 51.b/5

{*AI95-00366-01*} {*AI05-0065-1*} [A type is said to *support external streaming* if Read and Write attributes are provided for sending values of such a type between active partitions, with Write marshalling the representation, and Read unmarshalling the representation.] A limited type supports external streaming only if it has available Read and Write attributes. A type with a part that is of a nonremote access type supports external streaming only if that access type or the type of some part that includes the access type component, has Read and Write attributes that have been specified via an attribute_definition_clause, and that attribute_definition_clause is visible. [An anonymous access type does not support external streaming.]All other types (including remote access types, see E.2.2) support external streaming. 52/3

Ramification: A limited type with a part that is of a nonremote access type needs to satisfy both rules. 52.a/3

Erroneous Execution

{*AI95-00279-01*} {*AI95-00344-01*} If the internal tag returned by Descendant_Tag to T'Class'Input identifies a type that is not library-level and whose tag has not been created, or does not exist in the partition at the time of the call, execution is erroneous. 53/2

Ramification: The definition of Descendant_Tag prevents such a tag from being provided to T'Class'Input if T is a library-level type. However, this rule is needed for nested tagged types. 53.a/2

Implementation Requirements

{*8652/0040*} {*AI95-00108-01*} For every subtype *S* of a language-defined nonlimited specific type *T*, the output generated by S'Output or S'Write shall be readable by S'Input or S'Read, respectively. This rule applies across partitions if the implementation conforms to the Distributed Systems Annex. 54/1

{*AI95-00195-01*} {*AI05-0092-1*} If Constraint_Error is raised during a call to Read because of failure of one the above checks, the implementation shall ensure that the discriminants of the actual parameter of Read are not modified. 55/3

Implementation Permissions

{*AI95-00195-01*} {*AI05-0092-1*} {*AI12-0445-1*} The number of calls performed by the predefined implementation of the stream-oriented attributes on the Read and Write operations of the stream type is unspecified. An implementation may take advantage of this permission to perform internal buffering. 56/5

However, all the calls on the Read and Write operations of the stream type used to implement an explicit invocation of a stream-oriented attribute shall take place before this invocation returns. An explicit invocation is one appearing explicitly in the program text, possibly through a generic instantiation (see 12.3).

56.1/5 {*AI05-0023-1*} {*AI05-0264-1*} {*AI12-0445-1*} If *T* is a discriminated type and its discriminants have defaults, then in two cases an execution of the default implementation of S'Read is not required to create an anonymous object of type *T*: If the discriminant values that are read in are equal to the corresponding discriminant values of *Item*, then creation of a new object of type *T* may be bypassed and *Item* may be used instead. If they are not equal and *Item* is a constrained variable, then Constraint_Error may be raised at that point, before any further values are read from the stream and before the object of type *T* is created.

56.2/3 {*AI05-0023-1*} A default implementation of S'Input that calls the default implementation of S'Read may create a constrained anonymous object with discriminants that match those in the stream.

56.a/3 **Implementation Note:** This allows the combined executions of S'Input and S'Read to create one object of type *T* instead of two. If this option is exercised, then:

56.b/3 - The discriminants are read from the stream by S'Input, not S'Read.

56.c/3 - S'Input declares an object of type *T* constrained by the discriminants read from the stream, not an unconstrained object.

56.d/3 - The discriminant values that S'Read would normally have read from the stream are read from Item instead.

56.e/3 - The permissions of the preceding paragraph then apply and no object of type *T* need be created by the execution of S'Read.

57/5 NOTE 1 {*AI12-0442-1*} For a definite subtype S of a type *T*, only *T*'Write and *T*'Read are necessary to pass an arbitrary value of the subtype through a stream. For an indefinite subtype S of a type *T*, *T*'Output and *T*'Input will normally be necessary, since *T*'Write and *T*'Read do not pass bounds, discriminants, or tags.

58 NOTE 2 User-specified attributes of S'Class are not inherited by other class-wide types descended from S.

Examples

59 *Example of user-defined Write attribute:*

60/2
```
{AI95-00441-01} procedure My_Write(
  Stream : not null access Ada.Streams.Root_Stream_Type'Class;
  Item   : My_Integer'Base);
for My_Integer'Write use My_Write;
```

60.a **Discussion:** *Example of network input/output using input output attributes:*

60.b
```
with Ada.Streams; use Ada.Streams;
generic
    type Msg_Type(<>) is private;
package Network_IO is
    -- Connect/Disconnect are used to establish the stream
    procedure Connect(...);
    procedure Disconnect(...);
```

60.c
```
    -- Send/Receive transfer messages across the network
    procedure Send(X : in Msg_Type);
    function Receive return Msg_Type;
private
    type Network_Stream is new Root_Stream_Type with ...
    procedure Read(...);  -- define Read/Write for Network_Stream
    procedure Write(...);
end Network_IO;
```

60.d
```
with Ada.Streams; use Ada.Streams;
package body Network_IO is
    Current_Stream : aliased Network_Stream;
    . . .
    procedure Connect(...) is ...;
    procedure Disconnect(...) is ...;
```

60.e
```
    procedure Send(X : in Msg_Type) is
    begin
        Msg_Type'Output(Current_Stream'Access, X);
    end Send;
```

```
    function Receive return Msg_Type is                                    60.f
    begin
        return Msg_Type'Input(Current_Stream'Access);
    end Receive;
end Network_IO;
```

Inconsistencies With Ada 95

{*8652/0040*} {*AI95-00108-01*} **Corrigendum:** Clarified how the default implementation for stream attributes is determined (eliminating conflicting language). The new wording provides that attributes for type extensions are created by composing the parent's attribute with those for the extension components if any. If a program was written assuming that the extension components were not included in the stream (as in original Ada 95), it would fail to work in the language as corrected by the Corrigendum. 60.g/2

{*AI95-00195-01*} **Amendment Correction:** Explicitly provided a permission that the number of calls to the underlying stream Read and Write operations may differ from the number determined by the canonical operations. If Ada 95 code somehow depended on the number of calls to Read or Write, it could fail with an Ada 2005 implementation. Such code is likely to be very rare; moreover, such code is really wrong, as the permission applies to Ada 95 as well. 60.h/2

Extensions to Ada 95

{*AI95-00270-01*} The Stream_Size attribute is new. It allows specifying the number of bits that will be streamed for a type. The Implementation Advice involving this also was changed; this is not incompatible because Implementation Advice does not have to be followed. 60.i/2

{*8652/0040*} {*AI95-00108-01*} {*AI95-00195-01*} {*AI95-00444-01*} **Corrigendum:** Limited types may have default constructed attributes if all of the parent and (for extensions) extension components have available attributes. Ada 2005 adds the notion of availability to patch up some holes in the Corrigendum model. 60.j/2

Wording Changes from Ada 95

{*8652/0009*} {*AI95-00137-01*} **Corrigendum:** Added wording to specify that these are operational attributes. 60.k/2

{*8652/0045*} {*AI95-00132-01*} **Corrigendum:** Clarified that End_Error is raised by the default implementation of Read and Input if the end of the stream is reached. (The result could have been abnormal without this clarification, thus this is not an inconsistency, as the programmer could not have depended on the previous behavior.) 60.l/2

{*AI95-00195-01*} Clarified that the default implementation of S'Input does normal initialization on the object that it passes to S'Read. 60.m/2

{*AI95-00195-01*} Explicitly stated that what is read from a stream when a required check fails is unspecified. 60.n/2

{*AI95-00251-01*} Defined availability and default implementations for types with progenitors. 60.o/2

{*AI95-00279-01*} Specified that Constraint_Error is raised if the internal tag retrieved for S'Class'Input is for some type not covered by S'Class or is abstract. We also explicitly state that the program is erroneous if the tag has not been created or does not currently exist in the partition. (Ada 95 did not specify what happened in these cases; it's very unlikely to have provided some useful result, so this is not considered an inconsistency.) 60.p/2

{*AI95-00344-01*} Added wording to support nested type extensions. S'Input and S'Output always raise Tag_Error for such extensions, and such extensions were not permitted in Ada 95, so this is neither an extension nor an incompatibility. 60.q/2

{*AI95-00366-01*} Defined *supports external streaming* to put all of the rules about “good” stream attributes in one place. This is used for distribution and for defining pragma Pure. 60.r/2

{*AI95-00441-01*} Added the **not null** qualifier to the first parameter of all of the stream attributes, so that the semantics doesn't change between Ada 95 and Ada 2005. This change is compatible, because mode conformance is required for subprograms specified as stream attributes, and null_exclusions are not considered for mode conformance. 60.s/2

{*AI95-00444-01*} Improved the wording to make it clear that we don't define the default implementations of attributes that cannot be called (that is, aren't “available”). Also clarified when inheritance takes place. 60.t/2

Incompatibilities With Ada 2005

{*AI05-0039-1*} **Correction:** Added a requirement that stream attributes be specified by a static subprogram name rather than a dynamic expression. Expressions cannot provide any useful functionality because of the freezing rules, and the possibility of them complicates implementations. Only pathological programs should be affected. 60.u/3

Extensions to Ada 2005

60.v/3 {*AI05-0007-1*} **Correction:** Stream attributes for scalar types can be specified with subprograms that take the first subtype as well as the base type. This eliminates confusion about which subtype is appropriate for attributes specified for partial views whose full type is a scalar type. It also eliminates a common user error (forgetting 'Base).

Wording Changes from Ada 2005

60.w/3 {*AI05-0023-1*} **Correction:** Corrected the definition of the default version S'Read and S'Input to be well-defined if S is a discriminated type with defaulted discriminants and some components require initialization and/or finalizations.

60.x/3 {*AI05-0065-1*} **Correction:** Defined remote access types to support external streaming, since that is their purpose.

60.y/3 {*AI05-0109-1*} **Correction:** Removed a misleading phrase which implies that Constraint_Error is raised for internal tags of the wrong type, when Tag_Error should be raised for such tags.

60.z/3 {*AI05-0139-2*} Clarified that arrays with convention Fortran are written in column-major order, rather then row-major order. This is necessary in order that streaming of Fortran arrays is efficient.

60.aa/3 {*AI05-0192-1*} **Correction:** Clarified that the profile of an inherited stream attribute is as defined for an inherited primitive subprogram, while the default implementation of the same attribute might have a different profile.

60.bb/3 {*AI05-0194-1*} **Correction:** Clarified that Stream_Size has no effect on and is not effected by user-defined stream attributes.

Inconsistencies With Ada 2012

60.cc/5 {*AI12-0419-1*} The switch from inheritance to “implicitly composed” aspects means that there exists an exceedingly unlikely case where Ada 2022 code will raise Constraint_Error where Ada 2012 code would not. That case requires deriving a constrained untagged composite type *C* from an unconstrained parent type *P*, using a type conversion to *P* of the Input attribute of *C*, **and** streaming in a value that violates the constraints of *C*. Simply using the Input attribute of *P* instead of that of *C* will restore the Ada 2012 behavior.

Extensions to Ada 2012

60.dd/4 {*AI12-0106-1*} **Corrigendum:** Defined how to specify a class-wide stream-oriented attribute using an aspect_specification. It was always intended that this was possible, but the method was not clear, as a class-wide type never has an explicit declaration.

Wording Changes from Ada 2012

60.ee/4 {*AI12-0030-1*} **Corrigendum:** Defined the runtime effect of stream attributes for untagged limited types, as there is a weird corner case where they can be called. We don't specify this as an inconsistency, as it doesn't make semantic sense to stream a task, and nothing useful could have been done with that, so it should not exist in any programs.

60.ff/4 {*AI12-0106-1*} **Corrigendum:** Clarified that the same Legality Rules apply when a stream-oriented attribute is specified via an aspect_specification as applied when it is specified via an attribute_definition_clause.

60.gg/5 {*AI12-0064-2*} {*AI12-0396-1*} Added the definition of Nonblocking (see 9.5) and Global (see 6.1.2) for stream-oriented attributes.

60.hh/5 {*AI12-0419-1*} Revised to define composition of stream-oriented attributes for untagged derived types in order to avoid using inheritance for these attributes/aspects.

13.14 Freezing Rules

1/3 {*AI05-0299-1*} [This subclause defines a place in the program text where each declared entity becomes “frozen”. A use of an entity, such as a reference to it by name, or (for a type) an expression of the type, causes freezing of the entity in some contexts, as described below. The Legality Rules forbid certain kinds of uses of an entity in the region of text where it is frozen.]

1.a **Reason:** This concept has two purposes: a compile-time one and a run-time one.

1.b The compile-time purpose of the freezing rules comes from the fact that the evaluation of static expressions depends on overload resolution, and overload resolution sometimes depends on the value of a static expression. (The dependence of static evaluation upon overload resolution is obvious. The dependence in the other direction is more subtle. There are three rules that require static expressions in contexts that can appear in declarative places: The expression in an attribute_designator shall be static. In a record aggregate, variant-controlling discriminants shall be static. In an array aggregate with more than one named association, the choices shall be static. The compiler needs to know the value of

these expressions in order to perform overload resolution and legality checking.) We wish to allow a compiler to evaluate static expressions when it sees them in a single pass over the compilation_unit. The freezing rules ensure that.

The run-time purpose of the freezing rules is called the “linear elaboration model”. This means that declarations are elaborated in the order in which they appear in the program text, and later elaborations can depend on the results of earlier ones. The elaboration of the declarations of certain entities requires run-time information about the implementation details of other entities. The freezing rules ensure that this information has been calculated by the time it is used. For example, suppose the initial value of a constant is the result of a function call that takes a parameter of type *T*. In order to pass that parameter, the size of type *T* has to be known. If *T* is composite, that size might be known only at run time. 1.c

(Note that in these discussions, words like “before” and “after” generally refer to places in the program text, as opposed to times at run time.) 1.d

Discussion: The “implementation details” we're talking about above are: 1.e

- For a tagged type, the implementations of all the primitive subprograms of the type — that is (in the canonical implementation model), the contents of the type descriptor, which contains pointers to the code for each primitive subprogram. 1.f
- For a type, the full type declaration of any parts (including the type itself) that are private. 1.g
- For a deferred constant, the full constant declaration, which gives the constant's value. (Since this information necessarily comes after the constant's type and subtype are fully known, there's no need to worry about its type or subtype.) 1.h
- For any entity, representation information specified by the user via representation items. Most representation items are for types or subtypes; however, various other kinds of entities, such as objects and subprograms, are possible. 1.i

{*AI05-0005-1*} Similar issues arise for incomplete types. However, we do not use freezing to prevent premature access; incomplete types have different, more severe, restrictions. Similar issues also arise for subprograms, protected operations, tasks and generic units. However, we do not use freezing to prevent premature access for those, either; 3.11 prevents problems with run-time Elaboration_Checks. Even so, freezing is used for these entities to prevent giving representation items too late (that is, after uses that require representation information, such as calls). 1.j/3

Language Design Principles

An evaluable construct should freeze anything that's needed to evaluate it. 1.k

However, if the construct is not evaluated where it appears, let it cause freezing later, when it is evaluated. This is the case for default_expressions and default_names. (Formal parameters, generic formal parameters, and components can have default_expressions or default_names.) 1.l

The compiler should be allowed to evaluate static expressions without knowledge of their context. (I.e. there should not be any special rules for static expressions that happen to occur in a context that requires a static expression.) 1.m

Compilers should be allowed to evaluate static expressions (and record the results) using the run-time representation of the type. For example, suppose Color'Pos(Red) = 1, but the internal code for Red is 37. If the value of a static expression is Red, some compilers might store 1 in their symbol table, and other compilers might store 37. Either compiler design should be feasible. 1.n

Compilers should never be required to detect erroneousness or exceptions at compile time (although it's very nice if they do). This implies that we should not require code-generation for a nonstatic expression of type *T* too early, even if we can prove that that expression will be erroneous, or will raise an exception. 1.o

Here's an example (modified from AI83-00039, Example 3): 1.p

```
type T is                                                    1.q
    record
        ...
    end record;
function F return T;
function G(X : T) return Boolean;
Y : Boolean := G(F); -- doesn't force T in Ada 83
for T use
    record
        ...
    end record;
```

AI83-00039 says this is legal. Of course, it raises Program_Error because the function bodies aren't elaborated yet. A one-pass compiler has to generate code for an expression of type T before it knows the representation of T. Here's a similar example, which AI83-00039 also says is legal: 1.r

1.s
```
package P is
    type T is private;
    function F return T;
    function G(X : T) return Boolean;
    Y : Boolean := G(F); -- doesn't force T in Ada 83
private
    type T is
        record
            ...
        end record;
end P;
```

1.t If T's size were dynamic, that size would be stored in some compiler-generated dope; this dope would be initialized at the place of the full type declaration. However, the generated code for the function calls would most likely allocate a temp of the size specified by the dope *before* checking for Program_Error. That dope would contain uninitialized junk, resulting in disaster. To avoid doing that, the compiler would have to determine, at compile time, that the expression will raise Program_Error.

1.u This is silly. If we're going to require compilers to detect the exception at compile time, we might as well formulate the rule as a legality rule.

1.v Compilers should not be required to generate code to load the value of a variable before the address of the variable has been determined.

1.w After an entity has been frozen, no further requirements may be placed on its representation (such as by a representation item or a full_type_declaration).

2 The *freezing* of an entity occurs at one or more places (*freezing points*) in the program text where the representation for the entity has to be fully determined. Each entity is frozen from its first freezing point to the end of the program text (given the ordering of compilation units defined in 10.1.4).

2.a **Ramification:** The “representation” for a subprogram includes its calling convention and means for referencing the subprogram body, either a “link-name” or specified address. It does not include the code for the subprogram body itself, nor its address if a link-name is used to reference the body.

2.1/3 {*AI05-0019-1*} {*AI05-0299-1*} This subclause also defines a place in the program text where the profile of each declared callable entity becomes *frozen*. A use of a callable entity causes freezing of its profile in some contexts, as described below. At the place where the profile of a callable entity becomes frozen, the entity itself becomes frozen.

3/5 {*8652/0014*} {*AI05-0017-1*} {*AI05-0019-1*} {*AI12-0103-1*} {*AI12-0155-1*} {*AI12-0168-1*} {*AI12-0373-1*} The end of a declarative_part, protected_body, or a declaration of a library package or generic library package, causes *freezing* of each entity and profile declared within it, as well as the entity itself in the case of the declaration of a library unit. A noninstance proper_body, body_stub, or entry_body causes freezing of each entity and profile declared before it within the same declarative_part.

3.a **Discussion:** This is worded carefully to handle nested packages and private types. Entities declared in a nested package_specification will be frozen by some containing construct.

3.b/5 {*AI05-0017-1*} {*AI12-0155-1*} An incomplete type declared in the private part of a library package_specification can be completed in the body. For other incomplete types (and in the bodies of library packages), the completion of the type will be frozen at the end of the package or declarative_part.

3.c/3 **Ramification:** {*AI05-0229-1*} The part about bodies does not say *immediately* within. A renaming-as-body does not have this property. Nor does an imported body

3.d/5 **Reason:** {*AI12-0300-1*} The reason bodies cause freezing is because we want proper_bodies and body_stubs to be interchangeable — one should be able to move a proper_body to a subunit, and vice versa, without changing the semantics. Clearly, anything that should cause freezing should do so even if it's inside a proper_body. However, if we make it a body_stub, then the compiler can't see that thing that should cause freezing. So we make body_stubs cause freezing, just in case they contain something that should cause freezing. But that means we need to do the same for proper_bodies.

3.e Another reason for bodies to cause freezing, there could be an added implementation burden if an entity declared in an enclosing declarative_part is frozen within a nested body, since some compilers look at bodies after looking at the containing declarative_part.

3.f/4 {*AI05-0177-1*} {*AI12-0103-1*} Note that null_procedure_declarations and expression_function_declarations (even when those are used as completions), as well as generic_instantiations and renames-as-bodies do not necessarily cause freezing; each have their own specific rules.

Ramification: {*AI12-0103-1*} {*AI12-0005-1*} Note that the rule about proper bodies causing freezing only applies in declarative_parts. All of the kinds of bodies (see 3.11.1 – keep in mind the difference from bodys) that are allowed in a package specification have their own freezing rules, so they don't need to be covered by the above rule. 3.g/5

{*8652/0046*} {*AI95-00106-01*} A construct that (explicitly or implicitly) references an entity can cause the *freezing* of the entity, as defined by subsequent paragraphs. At the place where a construct causes freezing, each name, expression, implicit_dereference[, or range] within the construct causes freezing: 4/1

Ramification: Note that in the sense of this paragraph, a subtype_mark "references" the denoted subtype, but not the type. 4.a

- {*AI05-0213-1*} The occurrence of a generic_instantiation causes freezing, except that a name which is a generic actual parameter whose corresponding generic formal parameter is a formal incomplete type (see 12.5.1) does not cause freezing. In addition, if a parameter of the instantiation is defaulted, the default_expression or default_name for that parameter causes freezing. 5/3

  Ramification: {*AI05-0213-1*} Thus, an actual parameter corresponding to a formal incomplete type parameter may denote an incomplete or private type which is not completely defined at the point of the generic_instantiation. 5.a/3

- {*AI12-0103-1*} {*AI12-0157-1*} At the occurrence of an expression_function_declaration that is a completion, the return expression of the expression function causes freezing. 5.1/4

  Reason: {*AI12-0103-1*} This rule prevents calls through access values to an expression that might have unfrozen parts. Typically, elaboration checks and other freezing rules prevent this, but in this case the completion is elaborated and since this is not a body it does not by itself freeze anything that precedes it. 5.b/4

- {*AI12-0132-1*} {*AI12-0157-1*} At the occurrence of a renames-as-body whose *callable_entity_*name denotes an expression function, the return expression of the expression function causes freezing. 5.2/4

- The occurrence of an object_declaration that has no corresponding completion causes freezing. 6

  Ramification: Note that this does not include a formal_object_declaration. 6.a

- The declaration of a record extension causes freezing of the parent subtype. 7

  Ramification: This combined with another rule specifying that primitive subprogram declarations shall precede freezing ensures that all descendants of a tagged type implement all of its dispatching operations. 7.a

  {*AI95-00251-01*} The declaration of a private extension does not cause freezing. The freezing is deferred until the full type declaration, which will necessarily be for a record extension, task, or protected type (the latter only for a limited private extension derived from an interface). 7.b/2

- {*AI95-00251-01*} The declaration of a record extension, interface type, task unit, or protected unit causes freezing of any progenitor types specified in the declaration. 7.1/2

  Reason: This rule has the same purpose as the one above: ensuring that all descendants of an interface tagged type implement all of its dispatching operations. As with the previous rule, a private extension does not freeze its progenitors; the full type declaration (which must have the same progenitors) will do that. 7.b.1/2

  Ramification: An interface type can be a parent as well as a progenitor; these rules are similar so that the location of an interface in a record extension does not have an effect on the freezing of the interface type. 7.b.2/2

- {*AI05-0183-1*} {*AI12-0396-1*} {*AI12-0407-1*} {*AI12-0439-1*} At the freezing point of the entity associated with an aspect_specification, any static expressions within the aspect_specification cause freezing, as do expressions or names in aspect_definitions for representation aspects, or operational aspects that have a corresponding operational attribute. Similarly, if an aspect_definition for an operational aspect, other than an assertion aspect, can affect the Name Resolution, Static Semantics, or Legality Rules of a subsequent construct, then any expressions or names within the aspect_definition cause freezing at the freezing point of the associated entity. Any static expressions within an aspect_specification also cause freezing at the end of the immediately enclosing declaration list. For the purposes of this rule, if there is no declared entity associated with an aspect_specification, the freezing point is considered to occur immediately following the aspect_specification. 7.2/5

8/4 {*8652/0046*} {*AI95-00106-01*} {*AI05-0177-1*} {*AI05-0183-1*} {*AI05-0157-1*} A static expression (other than within an aspect_specification) causes freezing where it occurs. An object name or nonstatic expression causes freezing where it occurs, unless the name or expression is part of a default_expression, a default_name, the return expression of an expression function, an aspect_specification, or a per-object expression of a component's constraint, in which case, the freezing occurs later as part of another construct or at the freezing point of an associated entity.

8.1/3 {*8652/0046*} {*AI95-00106-01*} {*AI05-0019-1*} An implicit call freezes the same entities and profiles that would be frozen by an explicit call. This is true even if the implicit call is removed via implementation permissions.

8.2/1 {*8652/0046*} {*AI95-00106-01*} If an expression is implicitly converted to a type or subtype *T*, then at the place where the expression causes freezing, *T* is frozen.

9 The following rules define which entities are frozen at the place where a construct causes freezing:

10/5 - {*AI12-0367-1*} At the place where an expression causes freezing, the type of the expression is frozen, unless the expression is an enumeration literal used as a discrete_choice of the array_aggregate of an enumeration_representation_clause or as the aspect_definition of a specification for aspect Default_Value.

10.a **Reason:** We considered making enumeration literals never cause freezing, which would be more upward compatible, but examples like the variant record aggregate (Discrim => Red, ...) caused us to change our mind. Furthermore, an enumeration literal is a static expression, so the implementation should be allowed to represent it using its representation.

10.a.1/5 {*AI12-0367-1*} We exclude uses of enumeration literals that are used in part for setting the representation of the type (aspect Default_Value is defined to be a representation aspect) so we don't freeze the type while determining its representation.

10.b **Ramification:** The following pathological example was legal in Ada 83, but is illegal in Ada 95:

10.c
```
package P1 is
    type T is private;
    package P2 is
        type Composite(D : Boolean) is
            record
                case D is
                    when False => Cf : Integer;
                    when True  => Ct : T;
                end case;
            end record;
    end P2;
    X : Boolean := P2."="( (False,1), (False,1) );
private
    type T is array(1..Func_Call) of Integer;
end;
```

10.d In Ada 95, the declaration of X freezes Composite (because it contains an expression of that type), which in turn freezes T (even though Ct does not exist in this particular case). But type T is not completely defined at that point, violating the rule that a type shall be completely defined before it is frozen. In Ada 83, on the other hand, there is no occurrence of the name T, hence no forcing occurrence of T.

10.1/4 - {*AI05-0019-1*} {*AI05-0177-1*} {*AI12-0157-1*} At the place where a function call causes freezing, the profile of the function is frozen. Furthermore, if a parameter of the call is defaulted, the default_expression for that parameter causes freezing. If the function call is to an expression function, the return expression of the expression function causes freezing.

10.e/3 **Reason:** {*AI05-0019-1*} This is the important rule for profile freezing: a call freezes the profile. That's because generating the call will need to know how the parameters are passed, and that will require knowing details of the types. Other uses of subprograms do not need to know about the parameters, and thus only freeze the subprogram, and not the profile.

10.f/3 Note that we don't need to consider procedure or entry calls, since a body freezes everything that precedes it, and the end of a declarative part freezes everything in the declarative part.

10.g/4 **Ramification:** {*AI05-0177-1*} {*AI12-0103-1*} {*AI12-0157-1*} Freezing of the return expression of an expression function only needs to be considered when the expression function is in the same compilation unit and there are no

intervening bodys; the end of a declarative_part or library package freezes everything in it, and a body freezes everything declared before it.

- {*AI05-0019-1*} {*AI05-0177-1*} {*AI05-0296-1*} {*AI12-0157-1*} At the place where a generic_instantiation causes freezing of a callable entity, the profile of that entity is frozen unless the formal subprogram corresponding to the callable entity has a parameter or result of a formal untagged incomplete type; if the callable entity is an expression function, the return expression of the expression function causes freezing. 10.2/4

  Reason: Elaboration of the generic might call the actual for one of its formal subprograms, so we need to know the profile and (for an expression function) expression. 10.h/3

- {*AI05-0177-1*} {*AI12-0157-1*} At the place where a use of the Access or Unchecked_Access attribute whose prefix denotes an expression function causes freezing, the return expression of the expression function causes freezing. 10.3/4

  Reason: This is needed to avoid calls to unfrozen expressions. Consider: 10.i/3

  ```
  package Pack is                                                                          10.j/3
     type Flub is range 0 .. 100;                                                          10.k/3
     function Foo (A : in Natural) return Natural is                                       10.l/3
        (A + Flub'Size); -- The expression is not frozen here.
  {AI12-0005-1}    type Bar is access function (A : in Natural) return Natural;          10.m/4
     P : Bar := Foo'Access; -- (A)                                                         10.n/3
     Val : Natural := P.all(5); -- (B)                                                     10.o/3
  end Pack;                                                                              10.p/3
  ```

  If point (A) did not freeze the expression of Foo (which freezes Flub), then the call at point (B) would be depending on the aspects of the unfrozen type Flub. That would be bad. 10.q/3

- At the place where a name causes freezing, the entity denoted by the name is frozen, unless the name is a prefix of an expanded name; at the place where an object name causes freezing, the nominal subtype associated with the name is frozen. 11

  Ramification: {*AI95-00114-01*} This only matters in the presence of deferred constants or access types; an object_declaration other than a deferred constant declaration causes freezing of the nominal subtype, plus all component junk. 11.a/2

  This paragraph was deleted.{*8652/0046*} {*AI95-00106-01*} 11.b/1

- {*8652/0046*} {*AI95-00106-01*} At the place where an implicit_dereference causes freezing, the nominal subtype associated with the implicit_dereference is frozen. 11.1/1

  Discussion: This rule ensures that X.D freezes the same entities that X.**all**.D does. Note that an implicit_dereference is neither a name nor expression by itself, so it isn't covered by other rules. 11.c/2

- [At the place where a range causes freezing, the type of the range is frozen.] 12

  Proof: This is consequence of the facts that expressions freeze their type, and the Range attribute is defined to be equivalent to a pair of expressions separated by "..".} 12.a

- At the place where an allocator causes freezing, the designated subtype of its type is frozen. If the type of the allocator is a derived type, then all ancestor types are also frozen. 13

  Ramification: Allocators also freeze the named subtype, as a consequence of other rules. 13.a

  The ancestor types are frozen to prevent things like this: 13.b

  ```
  type Pool_Ptr is access System.Storage_Pools.Root_Storage_Pool'Class;                  13.c
  function F return Pool_Ptr;

  package P is                                                                           13.d
      type A1 is access Boolean;
      type A2 is new A1;
      type A3 is new A2;
      X : A3 := new Boolean; -- Don't know what pool yet!
      for A1'Storage_Pool use F.all;
  end P;
  ```

  This is necessary because derived access types share their parent's pool. 13.e

14/3 • {*AI05-0019-1*} At the place where a profile is frozen, each subtype of the profile is frozen. If the corresponding callable entity is a member of an entry family, the index subtype of the family is frozen.

14.a/3 *This paragraph was deleted.*

15/5 • {*AI12-0186-1*} At the place where a subtype is frozen, its type is frozen. At the place where a type is frozen, any expressions or names within the full type definition cause freezing, other than those that occur within an access_type_definition or an access_definition; the first subtype, and any component subtypes, index subtypes, and parent subtype of the type are frozen as well. For a specific tagged type, the corresponding class-wide type is frozen as well. For a class-wide type, the corresponding specific type is frozen as well.

15.a **Ramification:** Freezing a type needs to freeze its first subtype in order to preserve the property that the subtype-specific aspects of statically matching subtypes are the same.

15.b Freezing an access type does not freeze its designated subtype.

15.1/3 • {*AI95-00341-01*} {*AI05-0019-1*} At the place where a specific tagged type is frozen, the primitive subprograms of the type are frozen. At the place where a type is frozen, any subprogram named in an attribute_definition_clause for the type is frozen.

15.c/2 **Reason:** We have a language design principle that all of the details of a specific tagged type are known at its freezing point. But that is only true if the primitive subprograms are frozen at this point as well. Late changes of Import and address clauses violate the principle.

15.d/2 **Implementation Note:** This rule means that no implicit call to Initialize or Adjust can freeze a subprogram (the type and thus subprograms would have been frozen at worst at the same point).

15.e/3 **Discussion:** {*AI05-0019-1*} The second sentence is the rule that makes it possible to check that only subprograms with convention Ada are specified in attribute_definition_clauses without jumping through hoops.

15.2/5 • {*AI12-0396-1*} At the place where a construct causes freezing, if the construct includes a check associated with some assertion aspect [(independent of whether the check is enabled)], or depends on the definition of some operational aspect as part of its Dynamic Semantics, any names or expressions in the aspect_definition for the aspect cause freezing.

15.f/5 **Ramification:** Aspects such as Constant_Indexing cause freezing when they are used — the name in a Constant_Indexing would cause freezing when a generalized_indexing that makes use of it causes freezing.

15.3/5 {*AI12-0155-1*} Notwithstanding the rest of this subclause, freezing an incomplete view has no effect.

15.g/5 **Ramification:** In particular, freezing an incomplete view does not freeze the completion of the view. For an incomplete type, once the completion of the incomplete type is seen, any further references to the type will be of the complete type, which will be frozen in the normal way. Legality Rules prevent all problems for incomplete types themselves.

15.h/5 In contrast, freezing a partial view does have an effect (the completion of the view is frozen and the program is illegal if it hasn't occurred yet).

Legality Rules

16 [The explicit declaration of a primitive subprogram of a tagged type shall occur before the type is frozen (see 3.9.2).]

16.a **Reason:** This rule is needed because (1) we don't want people dispatching to things that haven't been declared yet, and (2) we want to allow tagged type descriptors to be static (allocated statically, and initialized to link-time-known symbols). Suppose T2 inherits primitive P from T1, and then overrides P. Suppose P is called *before* the declaration of the overriding P. What should it dispatch to? If the answer is the new P, we've violated the first principle above. If the answer is the old P, we've violated the second principle. (A call to the new one necessarily raises Program_Error, but that's beside the point.)

16.b Note that a call upon a dispatching operation of type *T* will freeze *T*.

16.c We considered applying this rule to all derived types, for uniformity. However, that would be upward incompatible, so we rejected the idea. As in Ada 83, for an untagged type, the above call upon P will call the old P (which is arguably confusing).

To be honest: {*AI05-0222-1*} This rule only applies to "original" declarations and not to the completion of a primitive subprogram, even though a completion is technically an explicit declaration, and it may declare a primitive subprogram. 16.d/3

[A type shall be completely defined before it is frozen (see 3.11.1 and 7.3).] 17

[The completion of a deferred constant declaration shall occur before the constant is frozen (see 7.4).] 18

This paragraph was deleted.{*AI95-00114-01*} {*AI05-0299-1*} {*AI12-0181-1*} 18.a/5

{*8652/0009*} {*AI95-00137-01*} [An operational or representation item that directly specifies an aspect of an entity shall appear before the entity is frozen (see 13.1).] 19/1

Discussion: {*8652/0009*} {*AI95-00137-01*} From RM83-13.1(7). The wording here forbids freezing within the aspect_clause itself, which was not true of the Ada 83 wording. The wording of this rule is carefully written to work properly for type-related representation items. For example, an enumeration_representation_clause is illegal after the type is frozen, even though the _clause refers to the first subtype. 19.a/1

This paragraph was deleted.{*AI95-00114-01*} {*AI12-0181-1*} 19.a.1/5

Proof: {*AI95-00114-01*} {*AI12-0181-1*} The above Legality Rules are stated “officially” in the referenced subclauses. 19.b/5

Discussion: Here's an example that illustrates when freezing occurs in the presence of defaults: 19.c

```
type T is ...;                                                    19.d
function F return T;
type R is
    record
        C : T := F;
        D : Boolean := F = F;
    end record;
X : R;
```

Since the elaboration of R's declaration does not allocate component C, there is no need to freeze C's subtype at that place. Similarly, since the elaboration of R does not evaluate the default_expression “F = F”, there is no need to freeze the types involved at that point. However, the declaration of X *does* need to freeze these things. Note that even if component C did not exist, the elaboration of the declaration of X would still need information about T — even though D is not of type T, its default_expression requires that information. 19.e

Ramification: Although we define freezing in terms of the program text as a whole (i.e. after applying the rules of Clause 10), the freezing rules actually have no effect beyond compilation unit boundaries. 19.f

Reason: That is important, because Clause 10 allows some implementation definedness in the order of things, and we don't want the freezing rules to be implementation defined. 19.g

Ramification: These rules also have no effect in statements — they only apply within a single declarative_part, package_specification, task_definition, protected_definition, or protected_body. 19.h

Implementation Note: An implementation may choose to generate code for default_expressions and default_names in line at the place of use. Alternatively, an implementation may choose to generate thunks (subprograms implicitly generated by the compiler) for evaluation of defaults. Thunk generation cannot, in general, be done at the place of the declaration that includes the default. Instead, they can be generated at the first freezing point of the type(s) involved. (It is impossible to write a purely one-pass Ada compiler, for various reasons. This is one of them — the compiler needs to store a representation of defaults in its symbol table, and then walk that representation later, no earlier than the first freezing point.) 19.i

In implementation terms, the linear elaboration model can be thought of as preventing uninitialized dope. For example, the implementation might generate dope to contain the size of a private type. This dope is initialized at the place where the type becomes completely defined. It cannot be initialized earlier, because of the order-of-elaboration rules. The freezing rules prevent elaboration of earlier declarations from accessing the size dope for a private type before it is initialized. 19.j

{*AI05-0299-1*} 2.8 overrides the freezing rules in the case of unrecognized pragmas; similarly 13.1.1 overrides the freezing rules in the case of a specification of an unrecognized aspect. 19.k/3

{*8652/0009*} {*AI95-00137-01*} An aspect_clause for an entity should most certainly *not* be a freezing point for the entity. 19.l/1

Dynamic Semantics

{*AI95-00279-01*} The tag (see 3.9) of a tagged type T is created at the point where T is frozen. 20/2

Incompatibilities With Ada 83

20.a RM83 defines a forcing occurrence of a type as follows: “A forcing occurrence is any occurrence [of the name of the type, subtypes of the type, or types or subtypes with subcomponents of the type] other than in a type or subtype declaration, a subprogram specification, an entry declaration, a deferred constant declaration, a pragma, or a representation_clause for the type itself. In any case, an occurrence within an expression is always forcing.”

20.b It seems like the wording allows things like this:

20.c
```
type A is array(Integer range 1..10) of Boolean;
subtype S is Integer range A'Range;
    -- not forcing for A
```

20.d Occurrences within pragmas can cause freezing in Ada 95. (Since such pragmas are ignored in Ada 83, this will probably fix more bugs than it causes.)

Extensions to Ada 83

20.e In Ada 95, generic_formal_parameter_declarations do not normally freeze the entities from which they are defined. For example:

20.f
```
package Outer is
    type T is tagged limited private;
    generic
        type T2 is
            new T with private;  -- Does not freeze T
                                 -- in Ada 95.
    package Inner is
        ...
    end Inner;
private
    type T is ...;
end Outer;
```

20.g This is important for the usability of generics. The above example uses the Ada 95 feature of formal derived types. Examples using the kinds of formal parameters already allowed in Ada 83 are well known. See, for example, comments 83-00627 and 83-00688. The extensive use expected for formal derived types makes this issue even more compelling than described by those comments. Unfortunately, we are unable to solve the problem that explicit_generic_actual_parameters cause freezing, even though a package equivalent to the instance would not cause freezing. This is primarily because such an equivalent package would have its body in the body of the containing program unit, whereas an instance has its body right there.

Wording Changes from Ada 83

20.h The concept of freezing is based on Ada 83's concept of “forcing occurrences”. The first freezing point of an entity corresponds roughly to the place of the first forcing occurrence, in Ada 83 terms. The reason for changing the terminology is that the new rules do not refer to any particular “occurrence” of a name of an entity. Instead, we refer to “uses” of an entity, which are sometimes implicit.

20.i In Ada 83, forcing occurrences were used only in rules about representation_clauses. We have expanded the concept to cover private types, because the rules stated in RM83-7.4.1(4) are almost identical to the forcing occurrence rules.

20.j The Ada 83 rules are changed in Ada 95 for the following reasons:

20.k
- The Ada 83 rules do not work right for subtype-specific aspects. In an earlier version of Ada 9X, we considered allowing representation items to apply to subtypes other than the first subtype. This was part of the reason for changing the Ada 83 rules. However, now that we have dropped that functionality, we still need the rules to be different from the Ada 83 rules.

20.l
- The Ada 83 rules do not achieve the intended effect. In Ada 83, either with or without the AIs, it is possible to force the compiler to generate code that references uninitialized dope, or force it to detect erroneousness and exception raising at compile time.

20.m
- It was a goal of Ada 83 to avoid uninitialized access values. However, in the case of deferred constants, this goal was not achieved.

20.n
- The Ada 83 rules are not only too weak — they are also too strong. They allow loopholes (as described above), but they also prevent certain kinds of default_expressions that are harmless, and certain kinds of generic_declarations that are both harmless and very useful.

20.o/2
- {*AI95-00114-01*} Ada 83 had a case where an aspect_clause had a strong effect on the semantics of the program — 'Small. This caused certain semantic anomalies. There are more cases in Ada 95, because the attribute_definition_clause has been generalized.

Incompatibilities With Ada 95

{*8652/0046*} {*AI95-00106-01*} {*AI95-00341-01*} **Corrigendum:** Various freezing rules were added to fix holes in the rules. Most importantly, implicit calls are now freezing, which make some representation clauses illegal in Ada 2005 that were legal (but dubious) in Ada 95. **Amendment Correction:** Similarly, the primitive subprograms of a specific tagged type are frozen when the type is frozen, preventing dubious convention changes (and address clauses) after the freezing point. In both cases, the code is dubious and the workaround is easy. 20.p/2

Wording Changes from Ada 95

{*8652/0009*} {*AI95-00137-01*} **Corrigendum:** Added wording to specify that both operational and representation attributes must be specified before the type is frozen. 20.q/2

{*AI95-00251-01*} Added wording that declaring a specific descendant of an interface type freezes the interface type. 20.r/2

{*AI95-00279-01*} Added wording that defines when a tag is created for a type (at the freezing point of the type). This is used to specify checking for uncreated tags (see 3.9). 20.s/2

Incompatibilities With Ada 2005

{*AI05-0019-1*} **Correction:** Separated the freezing of the profile from the rest of a subprogram, in order to reduce the impact of the Ada 95 incompatibility noted above. (The effects were much more limiting than expected.) 20.t/3

Wording Changes from Ada 2005

{*AI05-0017-1*} **Correction:** Reworded so that incomplete types with a deferred completion aren't prematurely frozen. 20.u/3

{*AI05-0177-1*} Added freezing rules for expression functions; these are frozen at the point of call, not the point of declaration, like default expressions. 20.v/3

{*AI05-0183-1*} Added freezing rules for aspect_specifications; these are frozen at the freezing point of the associated entity, not the point of declaration. 20.w/3

{*AI05-0213-1*} Added freezing rules for formal incomplete types; the corresponding actual is not frozen. 20.x/3

Wording Changes from Ada 2012

{*AI12-0103-1*} {*AI12-0132-1*} **Corrigendum:** Clarified when and what an expression_function_declaration that is a completion or that is the target of a renames-as-body freezes. This is formally an incompatibility, but as all known implementations freeze expression functions more aggressively than allowed by either the old or new wording, practically this will be an extension. 20.y/4

{*AI12-0168-1*} **Correction:** Clarified that the implicit body created by an instance doesn't have any freezing effect. This was an unintentional change caused by the Technical Corrigendum 1 oversimplifying wording. 20.z/5

{*AI12-0155-1*} **Correction:** Clarified that incomplete types do not freeze in any case. The one known case where incomplete freezing was necessary has been plugged with a new Legality Rules (see 3.10.1). This matches the original intent (see Language Design Principles above) and eliminates whack-a-mole trying to allow such freezing without it having (almost) any effects. 20.aa/5

{*AI12-0186-1*} **Correction:** Clarified that the subtype names in an access type are not frozen at the point of the type declaration. This has always been true (there is an Ada 95-era AARM note that says so) but it didn't follow from the actual wording. Since the ACATS requires the AARM note to be true, no compiler could actually get this wrong, so no incompatibility is possible. 20.bb/5

{*AI12-0367-1*} **Correction:** Added a freezing exclusion for enumeration literals in the expression of a Default_Value aspect; otherwise, one could not set a default value for an enumeration type. 20.cc/5

{*AI12-0373-1*} Added missing definition of freezing of library units. 20.dd/5

{*AI12-0396-1*} **Correction:** Improved and clarified the freezing rules for aspect_specifications; these now depend on the kind of aspect. 20.ee/5

The Standard Libraries

Annex A
(normative)
Predefined Language Environment

[This Annex contains the specifications of library units that shall be provided by every implementation. There are three root library units: Ada, Interfaces, and System; other library units are children of these:] 1

2.a **Discussion:** In running text, we generally leave out the “Ada.” when referring to a child of Ada.

2.b **Reason:** We had no strict rule for which of Ada, Interfaces, or System should be the parent of a given library unit. However, we have tried to place as many things as possible under Ada, except that interfacing is a separate category, and we have tried to place library units whose use is highly nonportable under System.

Implementation Requirements

3/5 {*AI95-00434-01*} {*AI12-0052-1*} {*AI12-0114-1*} {*AI12-0200-1*} {*AI12-0439-1*} The implementation shall ensure that concurrent calls on any two (possibly the same) language-defined subprograms perform as specified, so long as all pairs of objects (one from each call) that are either denoted by parameters that can be passed by reference, or are designated by parameters of an access type, are nonoverlapping.

3.a.1/4 **Ramification:** {*AI12-0052-1*} {*AI12-0114-1*} So long as the parameters are disjoint, concurrent calls on the same language-defined subprogram, and concurrent calls on two different language-defined subprograms are required to work. But concurrent calls operating on overlapping objects (be they of the same or different language-defined subprograms) are *not* required to work (being an erroneous use of shared variables) unless both subprograms are required to pass the associated parameter by-copy.

3.a For example, simultaneous calls to Text_IO.Put will work properly, so long as they are going to two different files. On the other hand, simultaneous output to the same file constitutes erroneous use of shared variables.

3.b **To be honest:** Here, “language defined subprogram” means a language defined library subprogram, a subprogram declared in the visible part of a language defined library package, an instance of a language defined generic library subprogram, or a subprogram declared in the visible part of an instance of a language defined generic library package.

3.b.1/4 **Ramification:** {*AI12-0052-1*} This rule applies to all language-defined subprograms, including those defined in packages that manage some global state (like environment variables or the current directory). Unless specified above, such subprograms need to work when the explicit parameters are not overlapping; in particular, the existence of the global state is not considered.

3.c/4 {*AI12-0052-1*} The rule implies that any data local to the private part or body of the package (including global state as described above) has to be somehow protected against simultaneous access.

3.1/4 {*AI12-0052-1*} {*AI12-0159-1*} For the purpose of determining whether concurrent calls on text input-output subprograms are required to perform as specified above, when calling a subprogram within Text_IO or its children that implicitly operates on one of the default input-output files, the subprogram is considered to have a parameter of Current_Input or Current_Output (as appropriate).

{*AI05-0048-1*} If a descendant of a language-defined tagged type is declared, the implementation shall ensure that each inherited language-defined subprogram behaves as described in this Reference Manual. In particular, overriding a language-defined subprogram shall not alter the effect of any inherited language-defined subprogram. 3.2/3

Reason: This means that internally the implementation must not do redispatching unless it is required by the Standard. So when we say that some subprogram Bar is equivalent to Foo, overriding Foo for a derived type doesn't change the semantics of Bar, and in particular it means that Bar may no longer be equivalent to Foo. The word “equivalent” is always a bit of a lie anyway. 3.d/3

Implementation Permissions

The implementation may restrict the replacement of language-defined compilation units. The implementation may restrict children of language-defined library units (other than Standard). 4

Ramification: For example, the implementation may say, “you cannot compile a library unit called System” or “you cannot compile a child of package System” or “if you compile a library unit called System, it has to be a package, and it has to contain at least the following declarations: ...”. 4.a

Ramification: {*AI12-0112-1*} Implementations are of course allowed to make changes to the specifications of language-defined units, so long as those changes are semantically neutral (that is, no program could change legality or effect because of the changes). In particular, an implementation can **with** additional units (especially implementation-defined units) so long as those units do not change the elaboration of the language-defined unit. 4.b/5

Similarly, an implementation can add postconditions to language-defined subprograms, so long as those postconditions always evaluate to True. This is useful if the implementation can use those postconditions for optimization. 4.c/5

Wording Changes from Ada 83

Many of Ada 83's language-defined library units are now children of Ada or System. For upward compatibility, these are renamed as root library units (see J.1). 4.d

The order and lettering of the annexes has been changed. 4.e

Wording Changes from Ada 95

{*8652/0047*} {*AI95-00081-01*} **Corrigendum:** Units missing from the list of predefined units were added. 4.f/2

{*AI95-00424-01*} Added new units to the list of predefined units. 4.g/2

Wording Changes from Ada 2005

{*AI05-0048-1*} **Correction:** Added wording to ban redispatching unless it is explicitly required, in order to safeguard portability when overriding language-defined routines. 4.h/3

{*AI05-0060-1*} {*AI05-0206-1*} **Correction:** Added a permission to omit pragma Remote_Types from language-defined units if Annex E is not supported. This was later removed, as a better method of supporting the reason is now available. Note that this requires all implementations to provide minimal support for the Remote_Types categorization even if Annex E is not supported; being unable to compile language-defined units is not allowed. 4.i/3

{*AI05-0001-1*} {*AI05-0049-1*} {*AI05-0069-1*} {*AI05-0111-3*} {*AI05-0136-1*} {*AI05-0137-1*} {*AI05-0166-1*} {*AI05-0168-1*} Added various new units to the list of predefined units. 4.j/3

Incompatibilities With Ada 2012

{*AI12-0005-1*} When a new entity *E* is added to a package *P* that is **use**d in client code, *use clause conflicts* are possible. Specifically, if *P* is referenced in a use_clause, and an entity *F* with the same defining identifier as *E* is defined in some other package that is also referenced in a *use_clause*, the user-defined entity *F* may no longer be use-visible, resulting in errors. This is an incompatibility when the new entity is added to a language-defined package. Note that use clause conflicts are rare and easily fixed by using an expanded name. 4.k/5

Wording Changes from Ada 2012

{*AI12-0052-1*} {*AI12-0114-1*} {*AI12-0159-1*} **Corrigendum:** The rules requiring concurrent access of language-defined subprograms were expanded to include implicit Text_IO objects, overlapping objects designated by parameters of an access type, and simultaneous calls on different language-defined subprograms. While this might change behavior of some programs, it would do so by eliminating erroneous execution, so we don't consider this an inconsistency. 4.k.1/4

4.k.2/5 {*AI12-0200-1*} **Correction:** The rules requiring concurrent access of language-defined subprograms were clarified further.

4.l/5 {*AI12-0021-1*} {*AI12-0208-1*} {*AI12-0234-1*} {*AI12-0254-1*} {*AI12-0293-1*} {*AI12-0321-1*} {*AI12-0340-1*} Added various new units to the list of predefined units.

A.1 The Package Standard

1/3 {*AI05-0299-1*} This subclause outlines the specification of the package Standard containing all predefined identifiers in the language. The corresponding package body is not specified by the language.

2 The operators that are predefined for the types declared in the package Standard are given in comments since they are implicitly declared. Italics are used for pseudo-names of anonymous types (such as *root_real*) and for undefined information (such as *implementation-defined*).

2.a **Ramification:** All of the predefined operators are of convention Intrinsic.

Static Semantics

3 The library package Standard has the following declaration:

3.a **Implementation defined:** The names and characteristics of the numeric subtypes declared in the visible part of package Standard.

4/5
```
{AI12-0414-1} package Standard
   with Pure is
```

5
```
   type Boolean is (False, True);
```

6
```
   -- The predefined relational operators for this type are as follows:
```

7/1
```
{8652/0028} {AI95-00145-01}    -- function "="   (Left, Right : Boolean'Base)
return Boolean;
   -- function "/="  (Left, Right : Boolean'Base) return Boolean;
   -- function "<"   (Left, Right : Boolean'Base) return Boolean;
   -- function "<="  (Left, Right : Boolean'Base) return Boolean;
   -- function ">"   (Left, Right : Boolean'Base) return Boolean;
   -- function ">="  (Left, Right : Boolean'Base) return Boolean;
```

8
```
   -- The predefined logical operators and the predefined logical
   -- negation operator are as follows:
```

9/1
```
{8652/0028} {AI95-00145-01}    -- function "and" (Left, Right : Boolean'Base)
return Boolean'Base;
   -- function "or"  (Left, Right : Boolean'Base) return Boolean'Base;
   -- function "xor" (Left, Right : Boolean'Base) return Boolean'Base;
```

10/1
```
{8652/0028} {AI95-00145-01}    -- function "not" (Right : Boolean'Base) return
Boolean'Base;
```

11/2
```
{AI95-00434-01}     -- The integer type root_integer and the
   -- corresponding universal type universal_integer are predefined.
```

12
```
   type Integer is range implementation-defined;
```

13
```
   subtype Natural  is Integer range 0 .. Integer'Last;
   subtype Positive is Integer range 1 .. Integer'Last;
```

14
```
   -- The predefined operators for type Integer are as follows:
```

15
```
   -- function "="  (Left, Right : Integer'Base) return Boolean;
   -- function "/=" (Left, Right : Integer'Base) return Boolean;
   -- function "<"  (Left, Right : Integer'Base) return Boolean;
   -- function "<=" (Left, Right : Integer'Base) return Boolean;
   -- function ">"  (Left, Right : Integer'Base) return Boolean;
   -- function ">=" (Left, Right : Integer'Base) return Boolean;
```

16
```
   -- function "+"   (Right : Integer'Base) return Integer'Base;
   -- function "-"   (Right : Integer'Base) return Integer'Base;
   -- function "abs" (Right : Integer'Base) return Integer'Base;
```

```
   -- function "+"   (Left, Right : Integer'Base) return Integer'Base;                17
   -- function "-"   (Left, Right : Integer'Base) return Integer'Base;
   -- function "*"   (Left, Right : Integer'Base) return Integer'Base;
   -- function "/"   (Left, Right : Integer'Base) return Integer'Base;
   -- function "rem" (Left, Right : Integer'Base) return Integer'Base;
   -- function "mod" (Left, Right : Integer'Base) return Integer'Base;

   -- function "**"  (Left : Integer'Base; Right : Natural)                           18
   --                  return Integer'Base;

   -- The specification of each operator for the type                                 19
   -- root_integer, or for any additional predefined integer
   -- type, is obtained by replacing Integer by the name of the type
   -- in the specification of the corresponding operator of the type
   -- Integer. The right operand of the exponentiation operator
   -- remains as subtype Natural.

{AI95-00434-01}    -- The floating point type root_real and the                       20/2
   -- corresponding universal type universal_real are predefined.

   type Float is digits implementation-defined;                                       21

   -- The predefined operators for this type are as follows:                          22

   -- function "="   (Left, Right : Float) return Boolean;                           23
   -- function "/="  (Left, Right : Float) return Boolean;
   -- function "<"   (Left, Right : Float) return Boolean;
   -- function "<="  (Left, Right : Float) return Boolean;
   -- function ">"   (Left, Right : Float) return Boolean;
   -- function ">="  (Left, Right : Float) return Boolean;

   -- function "+"   (Right : Float) return Float;                                    24
   -- function "-"   (Right : Float) return Float;
   -- function "abs" (Right : Float) return Float;

   -- function "+"   (Left, Right : Float) return Float;                              25
   -- function "-"   (Left, Right : Float) return Float;
   -- function "*"   (Left, Right : Float) return Float;
   -- function "/"   (Left, Right : Float) return Float;

   -- function "**"  (Left : Float; Right : Integer'Base) return Float;               26

   -- The specification of each operator for the type root_real, or for               27
   -- any additional predefined floating point type, is obtained by
   -- replacing Float by the name of the type in the specification of the
   -- corresponding operator of the type Float.

   -- In addition, the following operators are predefined for the root                28
   -- numeric types:

   function "*" (Left : root_integer; Right : root_real)                              29
     return root_real;

   function "*" (Left : root_real;    Right : root_integer)                           30
     return root_real;

   function "/" (Left : root_real;    Right : root_integer)                           31
     return root_real;

   -- The type universal_fixed is predefined.                                         32
   -- The only multiplying operators defined between
   -- fixed point types are

   function "*" (Left : universal_fixed; Right : universal_fixed)                     33
     return universal_fixed;

   function "/" (Left : universal_fixed; Right : universal_fixed)                     34
     return universal_fixed;

{AI95-00230-01}    -- The type universal_access is predefined.                       34.1/2
   -- The following equality operators are predefined:

{AI95-00230-01}    function "=" (Left, Right: universal_access) return Boolean;      34.2/2
   function "/=" (Left, Right: universal_access) return Boolean;
```

35/3 {AI95-00415-01} {AI05-0181-1} {AI05-0248-1} -- The declaration of type Character is based on the standard ISO 8859-1 character set.

```
   -- There are no character literals corresponding to the positions for control characters.
   -- They are indicated in italics in this definition. See 3.5.2.

45

```
   Constraint_Error: exception;
   Program_Error   : exception;
   Storage_Error   : exception;
   Tasking_Error   : exception;

end Standard;
```

46

47

Standard has no private part.

48

Reason: This is important for portability. All library packages are children of Standard, and if Standard had a private part then it would be visible to all of them.

48.a

{*AI95-00285-01*} In each of the types Character, Wide_Character, and Wide_Wide_Character, the character literals for the space character (position 32) and the non-breaking space character (position 160) correspond to different values. Unless indicated otherwise, each occurrence of the character literal ' ' in this Reference Manual refers to the space character. Similarly, the character literals for hyphen (position 45) and soft hyphen (position 173) correspond to different values. Unless indicated otherwise, each occurrence of the character literal '–' in this Reference Manual refers to the hyphen character.

49/2

Dynamic Semantics

Elaboration of the body of Standard has no effect.

50

50.a **Discussion:** Note that the language does not define where this body appears in the environment declarative_part — see 10, “Program Structure and Compilation Issues”.

Implementation Permissions

51 An implementation may provide additional predefined integer types and additional predefined floating point types. Some or all of these types may be anonymous.

51.a **To be honest:** An implementation may add representation items to package Standard, for example to specify the internal codes of type Boolean, or the Small of type Duration.

Implementation Advice

52 If an implementation provides additional named predefined integer types, then the names should end with “Integer” as in “Long_Integer”. If an implementation provides additional named predefined floating point types, then the names should end with “Float” as in “Long_Float”.

52.a/2 **Implementation Advice:** If an implementation provides additional named predefined integer types, then the names should end with “Integer”. If an implementation provides additional named predefined floating point types, then the names should end with “Float”.

53 NOTE 1 Certain aspects of the predefined entities cannot be completely described in the language itself. For example, although the enumeration type Boolean can be written showing the two enumeration literals False and True, the short-circuit control forms cannot be expressed in the language.

54 NOTE 2 As explained in 8.1, “Declarative Region” and 10.1.4, “The Compilation Process”, the declarative region of the package Standard encloses every library unit and consequently the main subprogram; the declaration of every library unit is assumed to occur within this declarative region. Library_items are assumed to be ordered in such a way that there are no forward semantic dependences. However, as explained in 8.3, “Visibility”, the only library units that are visible within a given compilation unit are the library units named by all with_clauses that apply to the given unit, and moreover, within the declarative region of a given library unit, that library unit itself.

55 NOTE 3 If all block_statements of a program are named, then the name of each program unit can always be written as an expanded name starting with Standard (unless Standard is itself hidden). The name of a library unit cannot be a homograph of a name (such as Integer) that is already declared in Standard.

56 NOTE 4 The exception Standard.Numeric_Error is defined in J.6.

56.a **Discussion:** The declaration of Natural needs to appear between the declaration of Integer and the (implicit) declaration of the "**" operator for Integer, because a formal parameter of "**" is of subtype Natural. This would be impossible in normal code, because the implicit declarations for a type occur immediately after the type declaration, with no possibility of intervening explicit declarations. But we're in Standard, and Standard is somewhat magic anyway.

56.b Using Natural as the subtype of the formal of "**" seems natural; it would be silly to have a textual rule about Constraint_Error being raised when there is a perfectly good subtype that means just that. Furthermore, by not using Integer for that formal, it helps remind the reader that the exponent remains Natural even when the left operand is replaced with the derivative of Integer. It doesn't logically imply that, but it's still useful as a reminder.

56.c In any case, declaring these general-purpose subtypes of Integer close to Integer seems more readable than declaring them much later.

Extensions to Ada 83

56.d Package Standard is declared to be pure.

56.e **Discussion:** The introduction of the types Wide_Character and Wide_String is not an Ada 95 extension to Ada 83, since ISO WG9 has approved these as an authorized extension of the original Ada 83 standard that is part of that standard.

Wording Changes from Ada 83

56.f Numeric_Error is made obsolescent.

56.g The declarations of Natural and Positive are moved to just after the declaration of Integer, so that "**" can refer to Natural without a forward reference. There's no real need to move Positive, too — it just came along for the ride.

Extensions to Ada 95

56.h/2 {*AI95-00285-01*} Types Wide_Wide_Character and Wide_Wide_String are new.

Discussion: The inconsistencies associated with these types are documented in 3.5.2 and 3.6.3. 56.i/2

{*AI95-00230-01*} Type *universal_access* and the equality operations for it are new. 56.j/2

Wording Changes from Ada 95

{*8652/0028*} {*AI95-00145-01*} **Corrigendum:** Corrected the parameter type for the Boolean operators declared in Standard. 56.k/2

Wording Changes from Ada 2005

{*AI05-0181-1*} **Correction:** Since soft_hyphen (position 173) is defined to be nongraphic, gave it a name. 56.l/3

Discussion: The inconsistencies associated with this change are documented in 3.5. 56.m/3

A.2 The Package Ada

Static Semantics

The following language-defined library package exists: 1

```
{AI12-0414-1} package Ada                                    2/5
   with Pure is
end Ada;
```

{*AI12-0414-1*} Ada serves as the parent of most of the other language-defined library units; its declaration is empty. 3/5

Legality Rules

In the standard mode, it is illegal to compile a child of package Ada. 4

Reason: The intention is that mentioning, say, Ada.Text_IO in a with_clause is guaranteed (at least in the standard mode) to refer to the standard version of Ada.Text_IO. The user can compile a root library unit Text_IO that has no relation to the standard version of Text_IO. 4.a

Ramification: Note that Ada can have non-language-defined grandchildren, assuming the implementation allows it. Also, packages System and Interfaces can have children, assuming the implementation allows it. 4.b

Implementation Note: An implementation will typically support a nonstandard mode in which compiling the language defined library units is allowed. Whether or not this mode is made available to users is up to the implementer. 4.c

An implementation could theoretically have private children of Ada, since that would be semantically neutral. However, a programmer cannot compile such a library unit. 4.d

Extensions to Ada 83

{*AI05-0299-1*} This subclause is new to Ada 95. 4.e/3

A.3 Character Handling

{*AI95-00285-01*} {*AI05-0243-1*} {*AI05-0299-1*} This subclause presents the packages related to character processing: an empty declared pure package Characters and child packages Characters.Handling and Characters.Latin_1. The package Characters.Handling provides classification and conversion functions for Character data, and some simple functions for dealing with Wide_Character and Wide_Wide_Character data. The child package Characters.Latin_1 declares a set of constants initialized to values of type Character. 1/3

Extensions to Ada 83

{*AI05-0299-1*} This subclause is new to Ada 95. 1.a/3

Wording Changes from Ada 95

{*AI95-00285-01*} Included Wide_Wide_Character in this description; the individual changes are documented as extensions as needed. 1.b/2

A.3.1 The Packages Characters, Wide_Characters, and Wide_Wide_Characters

Static Semantics

1 The library package Characters has the following declaration:

2/5
```
{AI12-0414-1} package Ada.Characters
   with Pure is
end Ada.Characters;
```

3/2 {*AI95-00395-01*} The library package Wide_Characters has the following declaration:

4/5
```
{AI12-0414-1} package Ada.Wide_Characters
   with Pure is
end Ada.Wide_Characters;
```

5/2 {*AI95-00395-01*} The library package Wide_Wide_Characters has the following declaration:

6/5
```
{AI12-0414-1} package Ada.Wide_Wide_Characters
   with Pure is
end Ada.Wide_Characters;
```

Implementation Advice

7/3 {*AI95-00395-01*} {*AI05-0185-1*} If an implementation chooses to provide implementation-defined operations on Wide_Character or Wide_String (such as collating and sorting, etc.) it should do so by providing child units of Wide_Characters. Similarly if it chooses to provide implementation-defined operations on Wide_Wide_Character or Wide_Wide_String it should do so by providing child units of Wide_Wide_Characters.

7.a/2 **Implementation Advice:** Implementation-defined operations on Wide_Character, Wide_String, Wide_Wide_Character, and Wide_Wide_String should be child units of Wide_Characters or Wide_Wide_Characters.

Extensions to Ada 95

7.b/2 {*AI95-00395-01*} The packages Wide_Characters and Wide_Wide_Characters are new.

A.3.2 The Package Characters.Handling

Static Semantics

1 The library package Characters.Handling has the following declaration:

2/5
```
{AI95-00362-01} {AI95-00395-01} {AI12-0414-1} with Ada.Characters.Conversions;
package Ada.Characters.Handling
  with Pure is
```

```
--Character classification functions                                                    3
{AI05-0185-1} {AI12-0004-1}   function Is_Control           (Item : in Character)      4/5
return Boolean;
  function Is_Graphic           (Item : in Character) return Boolean;
  function Is_Letter            (Item : in Character) return Boolean;
  function Is_Lower             (Item : in Character) return Boolean;
  function Is_Upper             (Item : in Character) return Boolean;
  function Is_Basic             (Item : in Character) return Boolean;
  function Is_Digit             (Item : in Character) return Boolean;
  function Is_Decimal_Digit     (Item : in Character) return Boolean
                    renames Is_Digit;
  function Is_Hexadecimal_Digit (Item : in Character) return Boolean;
  function Is_Alphanumeric      (Item : in Character) return Boolean;
  function Is_Special           (Item : in Character) return Boolean;
  function Is_Line_Terminator   (Item : in Character) return Boolean;
  function Is_Mark              (Item : in Character) return Boolean;
  function Is_Other_Format      (Item : in Character) return Boolean;
  function Is_Punctuation_Connector (Item : in Character) return Boolean;
  function Is_Space             (Item : in Character) return Boolean;
  function Is_NFKC              (Item : in Character) return Boolean;

--Conversion functions for Character and String                                         5

  function To_Lower (Item : in Character) return Character;                           6
  function To_Upper (Item : in Character) return Character;
  function To_Basic (Item : in Character) return Character;

  function To_Lower (Item : in String) return String;                                 7
  function To_Upper (Item : in String) return String;
  function To_Basic (Item : in String) return String;

--Classifications of and conversions between Character and ISO 646                     8

  subtype ISO_646 is                                                                  9
    Character range Character'Val(0) .. Character'Val(127);

  function Is_ISO_646 (Item : in Character) return Boolean;                           10
  function Is_ISO_646 (Item : in String)    return Boolean;

  function To_ISO_646 (Item       : in Character;                                     11
                       Substitute : in ISO_646 := ' ')
    return ISO_646;

  function To_ISO_646 (Item       : in String;                                        12
                       Substitute : in ISO_646 := ' ')
    return String;

{AI95-00285-01} {AI95-00395-01} -- The functions Is_Character, Is_String, To_Character, To_String,   13/2
To_Wide_Character,
-- and To_Wide_String are obsolescent; see J.14.

Paragraphs 14 through 18 were deleted.

end Ada.Characters.Handling;                                                          19
```

Discussion: {*AI95-00395-01*} The with_clause for Ada.Characters.Conversions is needed for the definition of the obsolescent functions (see J.14). It would be odd to put this clause into J.14 as it was not present in Ada 95, and with_clauses are semantically neutral to clients anyway. 19.a/2

In the description below for each function that returns a Boolean result, the effect is described in terms of the conditions under which the value True is returned. If these conditions are not met, then the function returns False. 20

Each of the following classification functions has a formal Character parameter, Item, and returns a Boolean result. 21

Is_Control 22

True if Item is a control character. A *control character* is a character whose position is in one of the ranges 0..31 or 127..159.

23 Is_Graphic
True if Item is a graphic character. A *graphic character* is a character whose position is in one of the ranges 32..126 or 160..255.

24 Is_Letter True if Item is a letter. A *letter* is a character that is in one of the ranges 'A'..'Z' or 'a'..'z', or whose position is in one of the ranges 192..214, 216..246, or 248..255.

25 Is_Lower True if Item is a lower-case letter. A *lower-case letter* is a character that is in the range 'a'..'z', or whose position is in one of the ranges 223..246 or 248..255.

26 Is_Upper True if Item is an upper-case letter. An *upper-case letter* is a character that is in the range 'A'..'Z' or whose position is in one of the ranges 192..214 or 216.. 222.

27 Is_Basic True if Item is a basic letter. A *basic letter* is a character that is in one of the ranges 'A'..'Z' and 'a'..'z', or that is one of the following: 'Æ', 'æ', 'Ð', 'ð', 'Þ', 'þ', or 'ß'.

28 Is_Digit True if Item is a decimal digit. A *decimal digit* is a character in the range '0'..'9'.

29 Is_Decimal_Digit
A renaming of Is_Digit.

30 Is_Hexadecimal_Digit
True if Item is a hexadecimal digit. A *hexadecimal digit* is a character that is either a decimal digit or that is in one of the ranges 'A' .. 'F' or 'a' .. 'f'.

31 Is_Alphanumeric
True if Item is an alphanumeric character. An *alphanumeric character* is a character that is either a letter or a decimal digit.

32 Is_Special
True if Item is a special graphic character. A *special graphic character* is a graphic character that is not alphanumeric.

32.1/3 {*AI05-0185-1*} Is_Line_Terminator
True if Item is a character with position 10 .. 13 (Line_Feed, Line_Tabulation, Form_Feed, Carriage_Return) or 133 (Next_Line).

32.2/3 {*AI05-0185-1*} Is_Mark
Never True (no value of type Character has categories Mark, Non-Spacing or Mark, Spacing Combining).

32.3/3 {*AI05-0185-1*} Is_Other_Format
True if Item is a character with position 173 (Soft_Hyphen).

32.4/3 {*AI05-0185-1*} Is_Punctuation_Connector
True if Item is a character with position 95 ('_', known as Low_Line or Underscore).

32.5/3 {*AI05-0185-1*} Is_Space
True if Item is a character with position 32 (' ') or 160 (No_Break_Space).

32.6/5 {*AI12-0004-1*} {*AI12-0263-1*} {*AI12-0439-1*} {*AI12-0450-1*} Is_NFKC
True if Item can be present in a string normalized to Normalization Form KC (as defined by Clause 22 of ISO/IEC 10646:2020); this includes all characters except those with positions 160, 168, 170, 175, 178, 179, 180, 181, 184, 185, 186, 188, 189, and 190.

33 Each of the names To_Lower, To_Upper, and To_Basic refers to two functions: one that converts from Character to Character, and the other that converts from String to String. The result of each Character-to-Character function is described below, in terms of the conversion applied to Item, its formal Character parameter. The result of each String-to-String conversion is obtained by applying to each element of the function's String parameter the corresponding Character-to-Character conversion; the result is the null String if the value of the formal parameter is the null String. The lower bound of the result String is 1.

To_Lower Returns the corresponding lower-case value for Item if Is_Upper(Item), and returns Item otherwise. 34

To_Upper Returns the corresponding upper-case value for Item if Is_Lower(Item) and Item has an upper-case form, and returns Item otherwise. The lower case letters 'ß' and 'ÿ' do not have upper case forms. 35

To_Basic Returns the letter corresponding to Item but with no diacritical mark, if Item is a letter but not a basic letter; returns Item otherwise. 36

The following set of functions test for membership in the ISO 646 character range, or convert between ISO 646 and Character. 37

Is_ISO_646 38

The function whose formal parameter, Item, is of type Character returns True if Item is in the subtype ISO_646.

Is_ISO_646 39

The function whose formal parameter, Item, is of type String returns True if Is_ISO_646(Item(I)) is True for each I in Item'Range.

To_ISO_646 40

The function whose first formal parameter, Item, is of type Character returns Item if Is_ISO_646(Item), and returns the Substitute ISO_646 character otherwise.

To_ISO_646 41

The function whose first formal parameter, Item, is of type String returns the String whose Range is 1..Item'Length and each of whose elements is given by To_ISO_646 of the corresponding element in Item.

Paragraphs 42 through 49 were deleted.

NOTE 1 A basic letter is a letter without a diacritical mark. 50

NOTE 2 Except for the hexadecimal digits, basic letters, and ISO_646 characters, the categories identified in the classification functions form a strict hierarchy: 51

— Control characters 52

— Graphic characters 53

— Alphanumeric characters 54

— Letters 55

— Upper-case letters 56

— Lower-case letters 57

— Decimal digits 58

— Special graphic characters 59

Ramification: Thus each Character value is either a control character or a graphic character but not both; each graphic character is either an alphanumeric or special graphic but not both; each alphanumeric is either a letter or decimal digit but not both; each letter is either upper case or lower case but not both. 59.a

NOTE 3 {*AI05-0114-1*} There are certain characters which are defined to be lower case letters by ISO 10646 and are therefore allowed in identifiers, but are not considered lower case letters by Ada.Characters.Handling. 60/3

Reason: This is to maintain runtime compatibility with the Ada 95 definitions of these functions. We don't list the exact characters involved because they're likely to change in future character set standards; the list for ISO 10646:2011 can be found in AI05-0114-1. 60.a/3

Ramification: No version of Characters.Handling is intended to do portable (Ada-version independent) manipulation of Ada identifiers. The classification given by Wide_Characters.Handling will be correct for the current implementation for Ada 2012 identifiers, but it might not be correct for a different implementation or version of Ada. 60.b/3

Extensions to Ada 95

{*AI95-00362-01*} Characters.Handling is now Pure, so it can be used in pure units. 60.c/2

Incompatibilities With Ada 2005

60.d/3 {*AI05-0185-1*} Added additional classification routines so that Characters.Handling has all of the routines available in Wide_Characters.Handling. If Characters.Handling is referenced in a use_clause, and an entity *E* with a defining_identifier that is the same as one of the new functions is defined in a package that is also referenced in a use_clause, the entity *E* may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur.

Wording Changes from Ada 95

60.e/2 {*AI95-00285-01*} {*AI95-00395-01*} The conversion functions are made obsolescent; a more complete set is available in Characters.Conversions — see A.3.4.

60.f/3 {*AI95-00285-01*} {*AI05-0248-1*} We no longer talk about localized character sets; these are a nonstandard mode, which is none of our business.

Wording Changes from Ada 2005

60.g/3 {*AI05-0114-1*} **Correction:** Added a note to clarify that these functions don't have any relationship to the characters allowed in identifiers.

Incompatibilities With Ada 2012

60.h/5 {*AI12-0004-1*} Added an additional classification routine Is_NFKC. Therefore, a use clause conflict is possible; see the introduction of Annex A for more on this topic.

A.3.3 The Package Characters.Latin_1

1 The package Characters.Latin_1 declares constants for characters in ISO 8859-1.

1.a **Reason:** The constants for the ISO 646 characters could have been declared as renamings of objects declared in package ASCII, as opposed to explicit constants. The main reason for explicit constants was for consistency of style with the upper-half constants, and to avoid emphasizing the package ASCII.

Static Semantics

2 The library package Characters.Latin_1 has the following declaration:

3/5
```
{AI12-0414-1} package Ada.Characters.Latin_1
    with Pure is
```

4
```
   -- Control characters:
```

5
```
   NUL                    : constant Character := Character'Val(0);

end Ada.Characters.Latin_1;
```

Implementation Permissions

27 An implementation may provide additional packages as children of Ada.Characters, to declare names for the symbols of the local character set or other character sets.

Wording Changes from Ada 2005

27.a/3 {*AI05-0181-1*} **Correction:** Soft_Hyphen is not a graphic character, and thus a character literal for it is illegal. So we have to use the position value. This makes no semantic change to users of the constant.

A.3.4 The Package Characters.Conversions

Static Semantics

{*AI95-00395-01*} The library package Characters.Conversions has the following declaration: 1/2

```
{AI12-0414-1} package Ada.Characters.Conversions                                    2/5
   with Pure is

   function Is_Character (Item : in Wide_Character)      return Boolean;            3/2
   function Is_String    (Item : in Wide_String)         return Boolean;
   function Is_Character (Item : in Wide_Wide_Character) return Boolean;
   function Is_String    (Item : in Wide_Wide_String)    return Boolean;
   function Is_Wide_Character (Item : in Wide_Wide_Character)
      return Boolean;
   function Is_Wide_String    (Item : in Wide_Wide_String)
      return Boolean;

   function To_Wide_Character (Item : in Character) return Wide_Character;        4/2
   function To_Wide_String    (Item : in String)    return Wide_String;
   function To_Wide_Wide_Character (Item : in Character)
      return Wide_Wide_Character;
   function To_Wide_Wide_String    (Item : in String)
      return Wide_Wide_String;
   function To_Wide_Wide_Character (Item : in Wide_Character)
      return Wide_Wide_Character;
   function To_Wide_Wide_String    (Item : in Wide_String)
      return Wide_Wide_String;

   function To_Character (Item       : in Wide_Character;                         5/2
                          Substitute : in Character := ' ')
      return Character;
   function To_String    (Item       : in Wide_String;
                          Substitute : in Character := ' ')
      return String;
   function To_Character (Item :       in Wide_Wide_Character;

                    Substitute : in Character := ' ') return String;
```

29/2 {*AI95-00395-01*} Returns the String whose range is 1..Item'Length and each of whose elements is given by To_Character of the corresponding element in Item.

30/2
```
function To_Wide_String (Item : in String) return Wide_String;
```

31/2 {*AI95-00395-01*} Returns the Wide_String whose range is 1..Item'Length and each of whose elements is given by To_Wide_Character of the corresponding element in Item.

32/2
```
function To_Wide_String (Item :       in Wide_Wide_String;
                         Substitute : in Wide_Character := ' ')
   return Wide_String;
```

33/2 {*AI95-00395-01*} Returns the Wide_String whose range is 1..Item'Length and each of whose elements is given by To_Wide_Character of the corresponding element in Item with the given Substitute Wide_Character.

```
function To_Wide_Wide_String (Item : in String) return Wide_Wide_String;
function To_Wide_Wide_String (Item : in Wide_String)
   return Wide_Wide_String;
```

34/2

{*AI95-00395-01*} Returns the Wide_Wide_String whose range is 1..Item'Length and each of whose elements is given by To_Wide_Wide_Character of the corresponding element in Item.

35/2

Extensions to Ada 95

{*AI95-00395-01*} The package Characters.Conversions is new, replacing functions previously found in Characters.Handling.

35.a/2

A.3.5 The Package Wide_Characters.Handling

{*AI05-0185-1*} The package Wide_Characters.Handling provides operations for classifying Wide_Characters and case folding for Wide_Characters.

1/3

Static Semantics

{*AI05-0185-1*} The library package Wide_Characters.Handling has the following declaration:

2/3

```
{AI05-0185-1} {AI05-0266-1} {AI12-0414-1} package Ada.Wide_Characters.Handling
   with Pure is
```

3/5

```
{AI05-0266-1}    function Character_Set_Version return String;
```

4/3

```
   function Is_Control (Item : Wide_Character) return Boolean;
```

5/3

```
   function Is_Letter (Item : Wide_Character) return Boolean;
```

6/3

```
   function Is_Lower (Item : Wide_Character) return Boolean;
```

7/3

```
   function Is_Upper (Item : Wide_Character) return Boolean;
```

8/3

```
{AI12-0260-1}    function Is_Basic (Item : Wide_Character) return Boolean;
```

8.1/5

```
   function Is_Digit (Item : Wide_Character) return Boolean;
```

9/3

```
   function Is_Decimal_Digit (Item : Wide_Character) return Boolean
      renames Is_Digit;
```

10/3

```
   function Is_Hexadecimal_Digit (Item : Wide_Character) return Boolean;
```

11/3

```
   function Is_Alphanumeric (Item : Wide_Character) return Boolean;
```

12/3

```
   function Is_Special (Item : Wide_Character) return Boolean;
```

13/3

```
   function Is_Line_Terminator (Item : Wide_Character) return Boolean;
```

14/3

```
   function Is_Mark (Item : Wide_Character) return Boolean;
```

15/3

```
   function Is_Other_Format (Item : Wide_Character) return Boolean;
```

16/3

```
   function Is_Punctuation_Connector (Item : Wide_Character) return Boolean;
```

17/3

```
   function Is_Space (Item : Wide_Character) return Boolean;
```

18/3

```
{AI12-0004-1}    function Is_NFKC (Item : Wide_Character) return Boolean;
```

18.1/5

```
   function Is_Graphic (Item : Wide_Character) return Boolean;
```

19/3

```
   function To_Lower (Item : Wide_Character) return Wide_Character;
   function To_Upper (Item : Wide_Character) return Wide_Character;
```

20/3

```
{AI12-0260-1}    function To_Basic (Item : Wide_Character) return Wide_Character;
```

20.1/5

```
   function To_Lower (Item : Wide_String) return Wide_String;
   function To_Upper (Item : Wide_String) return Wide_String;
```

21/3

```
{AI12-0260-1}    function To_Basic (Item : Wide_String) return Wide_String;
```

21.1/5

```
end Ada.Wide_Characters.Handling;
```

22/3

{*AI05-0185-1*} The subprograms defined in Wide_Characters.Handling are locale independent.

23/3

24/3 `function Character_Set_Version return String;`

25/3 {*AI05-0266-1*} Returns an implementation-defined identifier that identifies the version of the character set standard that is used for categorizing characters by the implementation.

26/3 `function Is_Control (Item : Wide_Character) return Boolean;`

27/3 {*AI05-0185-1*} Returns True if the Wide_Character designated by Item is categorized as other_control; otherwise returns False.

28/3 `function Is_Letter (Item : Wide_Character) return Boolean;`

29/3 {*AI05-0185-1*} Returns True if the Wide_Character designated by Item is categorized as letter_uppercase, letter_lowercase, letter_titlecase, letter_modifier, letter_other, or number_letter; otherwise returns False.

30/3 `function Is_Lower (Item : Wide_Character) return Boolean;`

31/3 {*AI05-0185-1*} Returns True if the Wide_Character designated by Item is categorized as letter_lowercase; otherwise returns False.

32/3 `function Is_Upper (Item : Wide_Character) return Boolean;`

33/3 {*AI05-0185-1*} Returns True if the Wide_Character designated by Item is categorized as letter_uppercase; otherwise returns False.

33.1/5 `function Is_Basic (Item : Wide_Character) return Boolean;`

33.2/5 {*AI12-0260-1*} {*AI12-0450-1*} Returns True if the Wide_Character designated by Item has no Decomposition Mapping in the code charts of ISO/IEC 10646:2020; otherwise returns False.

33.a/5 **Implementation Note:** Decomposition Mapping is defined in Clause 33 of ISO/IEC 10646:2020. Machine-readable (and normative!) versions of this can be found as Character Decomposition Mapping, described in file http://www.unicode.org/Public/UCD/latest/ucd/UnicodeData.txt, field 5 (which is the 6th item, Unicode counts from zero).

34/3 `function Is_Digit (Item : Wide_Character) return Boolean;`

35/3 {*AI05-0185-1*} Returns True if the Wide_Character designated by Item is categorized as number_decimal; otherwise returns False.

36/3 `function Is_Hexadecimal_Digit (Item : Wide_Character) return Boolean;`

37/3 {*AI05-0185-1*} Returns True if the Wide_Character designated by Item is categorized as number_decimal, or is in the range 'A' .. 'F' or 'a' .. 'f'; otherwise returns False.

38/3 `function Is_Alphanumeric (Item : Wide_Character) return Boolean;`

39/3 {*AI05-0185-1*} Returns True if the Wide_Character designated by Item is categorized as letter_uppercase, letter_lowercase, letter_titlecase, letter_modifier, letter_other, number_letter, or number_decimal; otherwise returns False.

40/3 `function Is_Special (Item : Wide_Character) return Boolean;`

41/3 {*AI05-0185-1*} Returns True if the Wide_Character designated by Item is categorized as graphic_character, but not categorized as letter_uppercase, letter_lowercase, letter_titlecase, letter_modifier, letter_other, number_letter, or number_decimal; otherwise returns False.

42/3 `function Is_Line_Terminator (Item : Wide_Character) return Boolean;`

43/3 {*AI05-0185-1*} Returns True if the Wide_Character designated by Item is categorized as separator_line or separator_paragraph, or if Item is a conventional line terminator character (Line_Feed, Line_Tabulation, Form_Feed, Carriage_Return, Next_Line); otherwise returns False.

```
function Is_Mark (Item : Wide_Character) return Boolean;
```
44/3

{*AI05-0185-1*} Returns True if the Wide_Character designated by Item is categorized as mark_non_spacing or mark_spacing_combining; otherwise returns False. 45/3

```
function Is_Other_Format (Item : Wide_Character) return Boolean;
```
46/3

{*AI05-0185-1*} Returns True if the Wide_Character designated by Item is categorized as other_format; otherwise returns False. 47/3

```
function Is_Punctuation_Connector (Item : Wide_Character) return Boolean;
```
48/3

{*AI05-0185-1*} Returns True if the Wide_Character designated by Item is categorized as punctuation_connector; otherwise returns False. 49/3

```
function Is_Space (Item : Wide_Character) return Boolean;
```
50/3

{*AI05-0185-1*} Returns True if the Wide_Character designated by Item is categorized as separator_space; otherwise returns False. 51/3

```
function Is_NFKC (Item : Wide_Character) return Boolean;
```
51.1/5

{*AI12-0004-1*} {*AI12-0263-1*} {*AI12-0439-1*} {*AI12-0450-1*} Returns True if the Wide_Character designated by Item can be present in a string normalized to Normalization Form KC (as defined by Clause 22 of ISO/IEC 10646:2020), otherwise returns False. 51.2/5

Reason: Wide_Characters for which this function returns False are not allowed in identifiers (see 2.3) even if they are categorized as letters or digits. 51.a/5

Implementation Note: This function returns False if the Unicode property NFKC Quick Check (NFKC_QC in the files) has the value No. See the Implementation Notes in 2.3 for the source of this property. 51.b/5

Discussion: A string for which Is_NFKC is true for every character may still not be in Normalization Form KC, as Is_NFKC returns true for characters that are dependent on characters around them as to whether they are removed by normalization. Ada does not provide a full normalization operation (it is complex and expensive). 51.c/5

```
function Is_Graphic (Item : Wide_Character) return Boolean;
```
52/3

{*AI05-0185-1*} Returns True if the Wide_Character designated by Item is categorized as graphic_character; otherwise returns False. 53/3

```
function To_Lower (Item : Wide_Character) return Wide_Character;
```
54/3

{*AI05-0185-1*} {*AI05-0266-1*} {*AI05-0299-1*} {*AI12-0263-1*} {*AI12-0450-1*} Returns the Simple Lowercase Mapping as defined by documents referenced in Clause 2 of ISO/IEC 10646:2020 of the Wide_Character designated by Item. If the Simple Lowercase Mapping does not exist for the Wide_Character designated by Item, then the value of Item is returned. 55/5

Discussion: {*AI12-0263-1*} {*AI12-0450-1*} The "documents referenced" means Unicode, Chapter 4 (specifically, section 4.2 — Case). The case mappings come from Unicode as ISO/IEC 10646:2020 does not include complete case mappings. See the Implementation Notes in subclause 1.1.4 for machine-readable versions of both Uppercase and Lowercase mappings. 55.a/5

```
function To_Lower (Item : Wide_String) return Wide_String;
```
56/3

{*AI05-0185-1*} Returns the result of applying the To_Lower conversion to each Wide_Character element of the Wide_String designated by Item. The result is the null Wide_String if the value of the formal parameter is the null Wide_String. The lower bound of the result Wide_String is 1. 57/3

```
function To_Upper (Item : Wide_Character) return Wide_Character;
```
58/3

{*AI05-0185-1*} {*AI05-0266-1*} {*AI05-0299-1*} {*AI12-0263-1*} {*AI12-0450-1*} Returns the Simple Uppercase Mapping as defined by documents referenced in Clause 2 of ISO/IEC 10646:2020 of the Wide_Character designated by Item. If the Simple Uppercase Mapping does not exist for the Wide_Character designated by Item, then the value of Item is returned. 59/5

60/3 `function To_Upper (Item : Wide_String) return Wide_String;`

61/3 {*AI05-0185-1*} Returns the result of applying the To_Upper conversion to each Wide_Character element of the Wide_String designated by Item. The result is the null Wide_String if the value of the formal parameter is the null Wide_String. The lower bound of the result Wide_String is 1.

61.1/5 `function To_Basic (Item : Wide_Character) return Wide_Character;`

61.2/5 {*AI12-0260-1*} {*AI12-0450-1*} Returns the Wide_Character whose code point is given by the first value of its Decomposition Mapping in the code charts of ISO/IEC 10646:2020 if any; returns Item otherwise.

61.3/5 `function To_Basic (Item : Wide_String) return Wide_String;`

61.4/5 {*AI12-0260-1*} Returns the result of applying the To_Basic conversion to each Wide_Character element of the Wide_String designated by Item. The result is the null Wide_String if the value of the formal parameter is the null Wide_String. The lower bound of the result Wide_String is 1.

Implementation Advice

62/3 {*AI05-0266-1*} The string returned by Character_Set_Version should include either “10646:” or “Unicode”.

62.a.1/3 **Implementation Advice:** The string returned by Wide_Characters.Handling.Character_Set_Version should include either “10646:” or “Unicode”.

62.a/5 **Discussion:** {*AI12-0263-1*} {*AI12-0450-1*} The intent is that the returned string include the year for 10646 (as in "10646:2020"), and the version number for Unicode (as in "Unicode 13.0"). We don't try to specify that further so we don't need to decide how to represent Corrigenda for 10646, nor which of these is preferred. (Giving a Unicode version is more accurate, as the case folding and mapping rules always come from a Unicode version [10646 just tells one to look at Unicode to get those], and the character classifications ought to be the same for equivalent versions, but we don't want to talk about non-ISO standards in an ISO standard.)

63/5 NOTE 1 {*AI05-0266-1*} {*AI12-0440-1*} {*AI12-0450-1*} The results returned by these functions can depend on which particular version of ISO/IEC 10646 is supported by the implementation (see 2.1).

64/5 NOTE 2 {*AI05-0286-1*} {*AI12-0449-1*} The case insensitive equality comparison routines provided in A.4.10 are also available for wide strings (see A.4.7).

Extensions to Ada 2005

64.a/3 {*AI05-0185-1*} {*AI05-0266-1*} The package Wide_Characters.Handling is new.

Incompatibilities With Ada 2012

64.b/5 {*AI12-0004-1*} {*AI12-0260-1*} Added additional classification routines Is_Basic and Is_NFKC, and additional conversion routine To_Basic. Therefore, a use clause conflict is possible; see the introduction of Annex A for more on this topic.

A.3.6 The Package Wide_Wide_Characters.Handling

1/3 {*AI05-0185-1*} The package Wide_Wide_Characters.Handling has the same contents as Wide_Characters.Handling except that each occurrence of Wide_Character is replaced by Wide_Wide_Character, and each occurrence of Wide_String is replaced by Wide_Wide_String.

Extensions to Ada 2005

1.a/3 {*AI05-0185-1*} The package Wide_Wide_Characters.Handling is new.

A.4 String Handling

1/3 {*AI95-00285-01*} {*AI05-0299-1*} This subclause presents the specifications of the package Strings and several child packages, which provide facilities for dealing with string data. Fixed-length, bounded-

length, and unbounded-length strings are supported, for String, Wide_String, and Wide_Wide_String. The string-handling subprograms include searches for pattern strings and for characters in program-specified sets, translation (via a character-to-character mapping), and transformation (replacing, inserting, overwriting, and deleting of substrings).

Extensions to Ada 83

{*AI05-0299-1*} This subclause is new to Ada 95. 1.a/3

Wording Changes from Ada 95

{*AI95-00285-01*} Included Wide_Wide_String in this description; the individual changes are documented as extensions as needed. 1.b/2

A.4.1 The Package Strings

The package Strings provides declarations common to the string handling packages. 1

Static Semantics

The library package Strings has the following declaration: 2

```
{AI12-0414-1} package Ada.Strings                                                    3/5
   with Pure is

{AI95-00285-01}    Space      : constant Character      := ' ';                     4/2
   Wide_Space : constant Wide_Character := ' ';
   Wide_Wide_Space : constant Wide_Wide_Character := ' ';

   Length_Error, Pattern_Error, Index_Error, Translation_Error : exception;         5

   type Alignment  is (Left, Right, Center);                                        6
   type Truncation is (Left, Right, Error);
   type Membership is (Inside, Outside);
   type Direction  is (Forward, Backward);
   type Trim_End   is (Left, Right, Both);
end Ada.Strings;
```

Incompatibilities With Ada 95

{*AI95-00285-01*} {*AI05-0005-1*} Constant Wide_Wide_Space is added to Ada.Strings. If Ada.Strings is referenced in a use_clause, and an entity *E* with a defining_identifier of Wide_Wide_Space is defined in a package that is also referenced in a use_clause, the entity *E* may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur. 6.a/3

A.4.2 The Package Strings.Maps

{*AI12-0445-1*} The package Strings.Maps defines the types, operations, and other entities necessary for character sets and character-to-character mappings. 1/5

Static Semantics

The library package Strings.Maps has the following declaration: 2

```
{AI95-00362-01} {AI12-0414-1} package Ada.Strings.Maps                               3/5
   with Pure is

{AI95-00161-01} {AI12-0399-1}     -- Representation for a set of character values:  4/5
   type Character_Set is private
      with Preelaborable_Initialization;

   Null_Set : constant Character_Set;                                                5
```

```
6        type Character_Range is
           record
              Low  : Character;
              High : Character;
           end record;
         -- Represents Character range Low..High
7        type Character_Ranges is array (Positive range <>) of Character_Range;
8        function To_Set    (Ranges : in Character_Ranges)return Character_Set;
9        function To_Set    (Span   : in Character_Range)return Character_Set;
10       function To_Ranges (Set    : in Character_Set)  return Character_Ranges;
11       function "="   (Left, Right : in Character_Set) return Boolean;
12       function "not" (Right : in Character_Set)       return Character_Set;
         function "and" (Left, Right : in Character_Set) return Character_Set;
         function "or"  (Left, Right : in Character_Set) return Character_Set;
         function "xor" (Left, Right : in Character_Set) return Character_Set;
         function "-"   (Left, Right : in Character_Set) return Character_Set;
13       function Is_In (Element : in Character;
                         Set     : in Character_Set)
            return Boolean;
14       function Is_Subset (Elements : in Character_Set;
                             Set      : in Character_Set)
            return Boolean;
15       function "<=" (Left  : in Character_Set;
                        Right : in Character_Set)
            return Boolean renames Is_Subset;
16       -- Alternative representation for a set of character values:
         subtype Character_Sequence is String;
17       function To_Set (Sequence  : in Character_Sequence)return Character_Set;
18       function To_Set (Singleton : in Character)     return Character_Set;
19       function To_Sequence (Set  : in Character_Set) return Character_Sequence;
20/5  {AI95-00161-01} {AI12-0399-1}    -- Representation for a character to character mapping:
            type Character_Mapping is private
               with Preelaborable_Initialization;
21          function Value (Map     : in Character_Mapping;
                            Element : in Character)
               return Character;
22          Identity : constant Character_Mapping;
23          function To_Mapping (From, To : in Character_Sequence)
               return Character_Mapping;
24          function To_Domain (Map : in Character_Mapping)
               return Character_Sequence;
            function To_Range  (Map : in Character_Mapping)
               return Character_Sequence;
25          type Character_Mapping_Function is
               access function (From : in Character) return Character;
26       private
            ... -- not specified by the language
         end Ada.Strings.Maps;
```

27 An object of type Character_Set represents a set of characters.

28 Null_Set represents the set containing no characters.

29 An object Obj of type Character_Range represents the set of characters in the range Obj.Low .. Obj.High.

30 An object Obj of type Character_Ranges represents the union of the sets corresponding to Obj(I) for I in Obj'Range.

```
function To_Set (Ranges : in Character_Ranges) return Character_Set;
```

{*AI05-0264-1*} If Ranges'Length=0 then Null_Set is returned; otherwise, the returned value represents the set corresponding to Ranges. 32/3

```
function To_Set (Span : in Character_Range) return Character_Set;
```

The returned value represents the set containing each character in Span.

```
function To_Ranges (Set : in Character_Set) return Character_Ranges;
```

{*AI05-0264-1*} If Set = Null_Set, then an empty Character_Ranges array is returned; otherwise, the shortest array of contiguous ranges of Character values in Set, in increasing order of Low, is returned. 36/3

```
function "=" (Left, Right : in Character_Set) return Boolean;
```

The function "=" returns True if Left and Right represent identical sets, and False otherwise.

Each of the logical operators "**not**", "**and**", "**or**", and "**xor**" returns a Character_Set value that represents the set obtained by applying the corresponding operation to the set(s) represented by the parameter(s) of the operator. "–"(Left, Right) is equivalent to "and"(Left, "not"(Right)).

Reason: The set minus operator is provided for efficiency.

```
function Is_In (Element : in Character;
                Set     : in Character_Set);
   return Boolean;
```

Is_In returns True if Element is in Set, and False otherwise.

```
function Is_Subset (Elements : in Character_Set;
                    Set      : in Character_Set)
   return Boolean;
```

Is_Subset returns True if Elements is a subset of Set, and False otherwise.

```
subtype Character_Sequence is String;
```

The Character_Sequence subtype is used to portray a set of character values and also to identify the domain and range of a character mapping.

Reason: Although a named subtype is redundant — the predefined type String could have been used for the parameter to To_Set and To_Mapping below — the use of a differently named subtype identifies the intended purpose of the parameter.

```
function To_Set (Sequence  : in Character_Sequence) return Character_Set;

function To_Set (Singleton : in Character)          return Character_Set;
```

Sequence portrays the set of character values that it explicitly contains (ignoring duplicates). Singleton portrays the set comprising a single Character. Each of the To_Set functions returns a Character_Set value that represents the set portrayed by Sequence or Singleton.

```
function To_Sequence (Set : in Character_Set) return Character_Sequence;
```

The function To_Sequence returns a Character_Sequence value containing each of the characters in the set represented by Set, in ascending order with no duplicates.

```
type Character_Mapping is private;
```

An object of type Character_Mapping represents a Character-to-Character mapping.

52
```
function Value (Map     : in Character_Mapping;
                Element : in Character)
   return Character;
```

53 The function Value returns the Character value to which Element maps with respect to the mapping represented by Map.

54 A character C *matches* a pattern character P with respect to a given Character_Mapping value Map if Value(Map, C) = P. A string S *matches* a pattern string P with respect to a given Character_Mapping if their lengths are the same and if each character in S matches its corresponding character in the pattern string P.

54.a **Discussion:** In an earlier version of the string handling packages, the definition of matching was symmetrical, namely C matches P if Value(Map,C) = Value(Map,P). However, applying the mapping to the pattern was confusing according to some reviewers. Furthermore, if the symmetrical version is needed, it can be achieved by applying the mapping to the pattern (via translation) prior to passing it as a parameter.

55 String handling subprograms that deal with character mappings have parameters whose type is Character_Mapping.

56
```
Identity : constant Character_Mapping;
```

57 Identity maps each Character to itself.

58
```
function To_Mapping (From, To : in Character_Sequence)
    return Character_Mapping;
```

59 To_Mapping produces a Character_Mapping such that each element of From maps to the corresponding element of To, and each other character maps to itself. If From'Length /= To'Length, or if some character is repeated in From, then Translation_Error is propagated.

60
```
function To_Domain (Map : in Character_Mapping) return Character_Sequence;
```

61 To_Domain returns the shortest Character_Sequence value D such that each character not in D maps to itself, and such that the characters in D are in ascending order. The lower bound of D is 1.

62
```
function To_Range  (Map : in Character_Mapping) return Character_Sequence;
```

63/1 {*8652/0048*} {*AI95-00151-01*} To_Range returns the Character_Sequence value R, such that if D = To_Domain(Map), then R has the same bounds as D, and D(I) maps to R(I) for each I in D'Range.

64 An object F of type Character_Mapping_Function maps a Character value C to the Character value F.**all**(C), which is said to *match* C with respect to mapping function F.

65 NOTE 1 Character_Mapping and Character_Mapping_Function are used both for character equivalence mappings in the search subprograms (such as for case insensitivity) and as transformational mappings in the Translate subprograms.

66 NOTE 2 To_Domain(Identity) and To_Range(Identity) each returns the null string.

66.a **Reason:** Package Strings.Maps is not pure, since it declares an access-to-subprogram type.

Examples

67/5 {*AI12-0429-1*} *Example of use of Strings.Maps.To_Mapping:*

68 To_Mapping("ABCD", "ZZAB") returns a Character_Mapping that maps 'A' and 'B' to 'Z', 'C' to 'A', 'D' to 'B', and each other Character to itself.

Extensions to Ada 95

68.a/2 {*AI95-00161-01*} **Amendment Correction:** Added pragma Preelaborable_Initialization to types Character_Set and Character_Mapping, so that they can be used to declare default-initialized objects in preelaborated units.

{*AI95-00362-01*} Strings.Maps is now Pure, so it can be used in pure units. 68.b/2

Wording Changes from Ada 95

{*8652/0048*} {*AI95-00151-01*} **Corrigendum:** Corrected the definition of the range of the result of To_Range, since the Ada 95 definition makes no sense. 68.c/2

A.4.3 Fixed-Length String Handling

The language-defined package Strings.Fixed provides string-handling subprograms for fixed-length strings; that is, for values of type Standard.String. Several of these subprograms are procedures that modify the contents of a String that is passed as an **out** or an **in out** parameter; each has additional parameters to control the effect when the logical length of the result differs from the parameter's length. 1

For each function that returns a String, the lower bound of the returned value is 1. 2

Discussion: {*AI95-00114-01*} Most operations that yield a String are provided both as a function and as a procedure. The functional form is possibly a more aesthetic style but may introduce overhead due to extra copying or dynamic memory usage in some implementations. Thus a procedural form, with an **in out** parameter so that all copying is done `in place', is also supplied. 2.a/2

The basic model embodied in the package is that a fixed-length string comprises significant characters and possibly padding (with space characters) on either or both ends. When a shorter string is copied to a longer string, padding is inserted, and when a longer string is copied to a shorter one, padding is stripped. The Move procedure in Strings.Fixed, which takes a String as an **out** parameter, allows the programmer to control these effects. Similar control is provided by the string transformation procedures. 3

Static Semantics

The library package Strings.Fixed has the following declaration: 4

```
{AI12-0241-1} {AI12-0302-1} with Ada.Strings.Maps;                                  5/5
package Ada.Strings.Fixed
   with Preelaborate, Nonblocking, Global => in out synchronized is
-- "Copy" procedure for strings of possibly different lengths                       6
   procedure Move (Source  : in  String;                                            7
                   Target  : out String;
                   Drop    : in  Truncation := Error;
                   Justify : in  Alignment  := Left;
                   Pad     : in  Character  := Space);
-- Search subprograms                                                               8
{AI95-00301-01}    function Index (Source  : in String;                             8.1/2
                   Pattern : in String;
                   From    : in Positive;
                   Going   : in Direction := Forward;
                   Mapping : in Maps.Character_Mapping := Maps.Identity)
      return Natural;
{AI95-00301-01}    function Index (Source  : in String;                             8.2/2
                   Pattern : in String;
                   From    : in Positive;
                   Going   : in Direction := Forward;

                  Count  : in Natural;
                  Pad    : in Character := Space)
      return String;
```

```
36        procedure Head (Source  : in out String;
                          Count   : in Natural;
                          Justify : in Alignment := Left;
                          Pad     : in Character := Space);
37        function Tail (Source : in String;
                         Count  : in Natural;
                         Pad    : in Character := Space)
             return String;
38        procedure Tail (Source  : in out String;
                          Count   : in Natural;
                          Justify : in Alignment := Left;
                          Pad     : in Character := Space);
39     --String constructor functions
40        function "*" (Left  : in Natural;
                        Right : in Character) return String;
41        function "*" (Left  : in Natural;
                        Right : in String) return String;
42     end Ada.Strings.Fixed;
```

43 The effects of the above subprograms are as follows.

```
44     procedure Move (Source  : in  String;
                       Target  : out String;
                       Drop    : in  Truncation := Error;
                       Justify : in  Alignment  := Left;
                       Pad     : in  Character  := Space);
```

45/3 {*AI05-0264-1*} The Move procedure copies characters from Source to Target. If Source has the same length as Target, then the effect is to assign Source to Target. If Source is shorter than Target, then:

46 • If Justify=Left, then Source is copied into the first Source'Length characters of Target.

47 • If Justify=Right, then Source is copied into the last Source'Length characters of Target.

48 • If Justify=Center, then Source is copied into the middle Source'Length characters of Target. In this case, if the difference in length between Target and Source is odd, then the extra Pad character is on the right.

49 • Pad is copied to each Target character not otherwise assigned.

50 If Source is longer than Target, then the effect is based on Drop.

51 • If Drop=Left, then the rightmost Target'Length characters of Source are copied into Target.

52 • If Drop=Right, then the leftmost Target'Length characters of Source are copied into Target.

53 • If Drop=Error, then the effect depends on the value of the Justify parameter and also on whether any characters in Source other than Pad would fail to be copied:

54 • If Justify=Left, and if each of the rightmost Source'Length-Target'Length characters in Source is Pad, then the leftmost Target'Length characters of Source are copied to Target.

55 • If Justify=Right, and if each of the leftmost Source'Length-Target'Length characters in Source is Pad, then the rightmost Target'Length characters of Source are copied to Target.

56 • Otherwise, Length_Error is propagated.

56.a **Ramification:** The Move procedure will work even if Source and Target overlap.

Reason: The order of parameters (Source before Target) corresponds to the order in COBOL's MOVE verb. 56.b

```
function Index (Source  : in String;                                    56.1/2
                Pattern : in String;
                From    : in Positive;
                Going   : in Direction := Forward;
                Mapping : in Maps.Character_Mapping := Maps.Identity)
   return Natural;

function Index (Source  : in String;
                Pattern : in String;
                From    : in Positive;
                Going   : in Direction := Forward;
                Mapping : in Maps.Character_Mapping_Function)
   return Natural;
```

{*AI95-00301-01*} {*AI05-0056-1*} Each Index function searches, starting from From, for a slice of Source, with length Pattern'Length, that matches Pattern with respect to Mapping; the parameter Going indicates the direction of the lookup. If Source is the null string, Index returns 0; otherwise, if From is not in Source'Range, then Index_Error is propagated. If Going = Forward, then Index returns the smallest index I which is greater than or equal to From such that the slice of Source starting at I matches Pattern. If Going = Backward, then Index returns the largest index I such that the slice of Source starting at I matches Pattern and has an upper bound less than or equal to From. If there is no such slice, then 0 is returned. If Pattern is the null string, then Pattern_Error is propagated. 56.2/3

Discussion: There is no default parameter for From; the default value would need to depend on other parameters (the bounds of Source and the direction Going). It is better to use overloaded functions rather than a special value to represent the default. 56.c/2

There is no default value for the Mapping parameter that is a Character_Mapping_Function; if there were, a call would be ambiguous since there is also a default for the Mapping parameter that is a Character_Mapping. 56.d/2

{*AI05-0056-1*} The language does not define when the Pattern_Error check is made. (That's because many common searching implementations require a nonempty pattern) That means that the result for a call like `Index ("", "")` could be 0 or could raise Pattern_Error. Similarly, in the call `Index ("", "", From => 2)`, the language does not define whether Pattern_Error or Index_Error is raised. 56.e/3

```
function Index (Source   : in String;                                   57
                Pattern  : in String;
                Going    : in Direction := Forward;
                Mapping  : in Maps.Character_Mapping
                              := Maps.Identity)
   return Natural;

function Index (Source   : in String;
                Pattern  : in String;
                Going    : in Direction := Forward;
                Mapping  : in Maps.Character_Mapping_Function)
   return Natural;
```

{*AI95-00301-01*} If Going = Forward, returns 58/2

```
   Index (Source, Pattern, Source'First, Forward, Mapping);             58.1/2
```

{*AI05-0264-1*} otherwise, returns 58.2/3

```
   Index (Source, Pattern, Source'Last, Backward, Mapping);             58.3/2
```

*This paragraph was deleted.*There is no default value for the Mapping parameter that is a Character_Mapping_Function; if there were, a call would be ambiguous since there is also a default for the Mapping parameter that is a Character_Mapping. 58.a/2

58.4/2
```
function Index (Source  : in String;
                Set     : in Maps.Character_Set;
                From    : in Positive;
                Test    : in Membership := Inside;
                Going   : in Direction := Forward)
   return Natural;
```

58.5/3 {*AI95-00301-01*} {*AI05-0056-1*} Index searches for the first or last occurrence of any of a set of characters (when Test=Inside), or any of the complement of a set of characters (when Test=Outside). If Source is the null string, Index returns 0; otherwise, if From is not in Source'Range, then Index_Error is propagated. Otherwise, it returns the smallest index I >= From (if Going=Forward) or the largest index I <= From (if Going=Backward) such that Source(I) satisfies the Test condition with respect to Set; it returns 0 if there is no such Character in Source.

59
```
function Index (Source : in String;
                Set    : in Maps.Character_Set;
                Test   : in Membership := Inside;
                Going  : in Direction  := Forward)
   return Natural;
```

60/2 {*AI95-00301-01*} If Going = Forward, returns

60.1/2
```
   Index (Source, Set, Source'First, Test, Forward);
```

60.2/3 {*AI05-0264-1*} otherwise, returns

60.3/2
```
   Index (Source, Set, Source'Last, Test, Backward);
```

60.4/2
```
function Index_Non_Blank (Source : in String;
                          From   : in Positive;
                          Going  : in Direction := Forward)
   return Natural;
```

60.5/2 {*AI95-00301-01*} Returns Index (Source, Maps.To_Set(Space), From, Outside, Going);

61
```
function Index_Non_Blank (Source : in String;
                          Going  : in Direction := Forward)
   return Natural;
```

62 Returns Index(Source, Maps.To_Set(Space), Outside, Going)

63
```
function Count (Source   : in String;
                Pattern  : in String;
                Mapping  : in Maps.Character_Mapping
                             := Maps.Identity)
   return Natural;

function Count (Source   : in String;
                Pattern  : in String;
                Mapping  : in Maps.Character_Mapping_Function)
   return Natural;
```

64 Returns the maximum number of nonoverlapping slices of Source that match Pattern with respect to Mapping. If Pattern is the null string then Pattern_Error is propagated.

64.a **Reason:** We say `maximum number' because it is possible to slice a source string in different ways yielding different numbers of matches. For example if Source is "ABABABA" and Pattern is "ABA", then Count yields 2, although there is a partitioning of Source that yields just 1 match, for the middle slice. Saying `maximum number' is equivalent to saying that the pattern match starts either at the low index or the high index position.

65
```
function Count (Source   : in String;
                Set      : in Maps.Character_Set)
   return Natural;
```

66 Returns the number of occurrences in Source of characters that are in Set.

```
procedure Find_Token (Source : in String;                                    66.1/3
                      Set    : in Maps.Character_Set;
                      From   : in Positive;
                      Test   : in Membership;
                      First  : out Positive;
                      Last   : out Natural);
```

{*AI05-0031-1*} If Source is not the null string and From is not in Source'Range, then Index_Error is raised. Otherwise, First is set to the index of the first character in Source(From .. Source'Last) that satisfies the Test condition. Last is set to the largest index such that all characters in Source(First .. Last) satisfy the Test condition. If no characters in Source(From .. Source'Last) satisfy the Test condition, First is set to From, and Last is set to 0. 66.2/3

```
procedure Find_Token (Source : in String;                                    67
                      Set    : in Maps.Character_Set;
                      Test   : in Membership;
                      First  : out Positive;
                      Last   : out Natural);
```

{*8652/0049*} {*AI95-00128-01*} {*AI05-0031-1*} Equivalent to Find_Token (Source, Set, Source'First, Test, First, Last). 68/3

Ramification: {*AI05-0031-1*} If Source'First is not in Positive, which can only happen for an empty string, this will raise Constraint_Error. 68.a/3

```
function Translate (Source  : in String;                                     69
                    Mapping : in Maps.Character_Mapping)
   return String;

function Translate (Source  : in String;
                    Mapping : in Maps.Character_Mapping_Function)
   return String;
```

Returns the string S whose length is Source'Length and such that S(I) is the character to which Mapping maps the corresponding element of Source, for I in 1..Source'Length. 70

```
procedure Translate (Source  : in out String;                                71
                     Mapping : in Maps.Character_Mapping);

procedure Translate (Source  : in out String;

                         Justify  : in Alignment  := Left;
                         Pad      : in Character  := Space);
```

76 Equivalent to Move(Replace_Slice(Source, Low, High, By), Source, Drop, Justify, Pad).

77
```
function Insert (Source   : in String;
                 Before   : in Positive;
                 New_Item : in String)
   return String;
```

78/3 {*AI05-0264-1*} Propagates Index_Error if Before is not in Source'First .. Source'Last+1; otherwise, returns Source(Source'First..Before–1) & New_Item & Source(Before..Source'Last), but with lower bound 1.

79
```
procedure Insert (Source   : in out String;
                  Before   : in Positive;
                  New_Item : in String;
                  Drop     : in Truncation := Error);
```

80 Equivalent to Move(Insert(Source, Before, New_Item), Source, Drop).

81
```
function Overwrite (Source   : in String;
                    Position : in Positive;
                    New_Item : in String)
   return String;
```

82/3 {*AI05-0264-1*} Propagates Index_Error if Position is not in Source'First .. Source'Last+1; otherwise, returns the string obtained from Source by consecutively replacing characters starting at Position with corresponding characters from New_Item. If the end of Source is reached before the characters in New_Item are exhausted, the remaining characters from New_Item are appended to the string.

83
```
procedure Overwrite (Source   : in out String;
                     Position : in Positive;
                     New_Item : in String;
                     Drop     : in Truncation := Right);
```

84 Equivalent to Move(Overwrite(Source, Position, New_Item), Source, Drop).

85
```
function Delete (Source  : in String;
                 From    : in Positive;
                 Through : in Natural)
   return String;
```

86/3 {*8652/0049*} {*AI95-00128-01*} {*AI05-0264-1*} If From <= Through, the returned string is Replace_Slice(Source, From, Through, ""); otherwise, it is Source with lower bound 1.

87
```
procedure Delete (Source  : in out String;
                  From    : in Positive;
                  Through : in Natural;
                  Justify : in Alignment := Left;
                  Pad     : in Character := Space);
```

88 Equivalent to Move(Delete(Source, From, Through), Source, Justify => Justify, Pad => Pad).

```
function Trim (Source : in String;                                    89
               Side   : in Trim_End)
  return String;
```

Returns the string obtained by removing from Source all leading Space characters (if Side = Left), all trailing Space characters (if Side = Right), or all leading and trailing Space characters (if Side = Both). 90

```
procedure Trim (Source  : in out String;                              91
                Side    : in Trim_End;
                Justify : in Alignment := Left;
                Pad     : in Character := Space);
```

Equivalent to Move(Trim(Source, Side), Source, Justify=>Justify, Pad=>Pad). 92

```
function Trim (Source : in String;                                    93
               Left   : in Maps.Character_Set;
               Right  : in Maps.Character_Set)
   return String;
```

Returns the string obtained by removing from Source all leading characters in Left and all trailing characters in Right. 94

```
procedure Trim (Source  : in out String;                              95
                Left    : in Maps.Character_Set;
                Right   : in Maps.Character_Set;
                Justify : in Alignment := Strings.Left;
                Pad     : in Character := Space);
```

Equivalent to Move(Trim(Source, Left, Right), Source, Justify => Justify, Pad=>Pad). 96

```
function Head (Source : in String;                                    97
               Count  : in Natural;
               Pad    : in Character := Space)
   return String;
```

{*AI05-0264-1*} Returns a string of length Count. If Count <= Source'Length, the string comprises the first Count characters of Source. Otherwise, its contents are Source concatenated with Count–Source'Length Pad characters. 98/3

```
procedure Head (Source  : in out String;                              99
                Count   : in Natural;
                Justify : in Alignment := Left;
                Pad     : in Character := Space);
```

Equivalent to Move(Head(Source, Count, Pad), Source, Drop=>Error, Justify=>Justify, Pad=>Pad). 100

```
function Tail (Source : in String;                                    101
               Count  : in Natural;
               Pad    : in Character := Space)
   return String;
```

{*AI05-0264-1*} Returns a string of length Count. If Count <= Source'Length, the string comprises the last Count characters of Source. Otherwise, its contents are Count-Source'Length Pad characters concatenated with Source. 102/3

```
procedure Tail (Source  : in out String;                              103
                Count   : in Natural;
                Justify : in Alignment := Left;
                Pad     : in Character := Space);
```

Equivalent to Move(Tail(Source, Count, Pad), Source, Drop=>Error, Justify=>Justify, Pad=>Pad). 104

105
```
function "*" (Left  : in Natural;
              Right : in Character) return String;

function "*" (Left  : in Natural;
              Right : in String) return String;
```

106/1 {*8652/0049*} {*AI95-00128-01*} These functions replicate a character or string a specified number of times. The first function returns a string whose length is Left and each of whose elements is Right. The second function returns a string whose length is Left*Right'Length and whose value is the null string if Left = 0 and otherwise is (Left–1)*Right & Right with lower bound 1.

107/5 NOTE 1 {*AI05-0264-1*} {*AI12-0442-1*} In the Index and Count functions taking Pattern and Mapping parameters, for there to be a match, the actual String parameter passed to Pattern can contain only characters occurring as target characters of the mapping.

108 NOTE 2 In the Insert subprograms, inserting at the end of a string is obtained by passing Source'Last+1 as the Before parameter.

109 NOTE 3 If a null Character_Mapping_Function is passed to any of the string handling subprograms, Constraint_Error is propagated.

Incompatibilities With Ada 95

109.a/3 {*AI95-00301-01*} {*AI05-0005-1*} Overloaded versions of Index and Index_Non_Blank are added to Strings.Fixed. If Strings.Fixed is referenced in a use_clause, and an entity *E* with a defining_identifier of Index or Index_Non_Blank is defined in a package that is also referenced in a use_clause, the entity *E* may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur.

Wording Changes from Ada 95

109.b/2 {*8652/0049*} {*AI95-00128-01*} **Corrigendum:** Clarified that Find_Token may raise Constraint_Error if Source'First is not in Positive (which is only possible for a null string).

109.c/2 {*8652/0049*} {*AI95-00128-01*} **Corrigendum:** Clarified that Replace_Slice, Delete, and "*" always return a string with lower bound 1.

Incompatibilities With Ada 2005

109.d/3 {*AI05-0031-1*} An overloaded version of Find_Token is added to Strings.Fixed. If Strings.Fixed is referenced in a use_clause, and an entity *E* with a defining_identifier of Find_Token is defined in a package that is also referenced in a use_clause, the entity *E* may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur.

Wording Changes from Ada 2005

109.e/3 {*AI05-0056-1*} **Correction:** Clarified that Index never raises Index_Error if the source string is null.

A.4.4 Bounded-Length String Handling

1/5 {*AI12-0445-1*} The language-defined package Strings.Bounded provides a generic package each of whose instances yields a private type Bounded_String and a set of operations. An object of a particular Bounded_String type represents a String whose low bound is 1 and whose length can vary conceptually between 0 and a maximum size established at the generic instantiation. The subprograms for fixed-length string handling are either overloaded directly for Bounded_String, or are modified as necessary to reflect the variability in length. Additionally, since the Bounded_String type is private, appropriate constructor and selector operations are provided.

1.a **Reason:** Strings.Bounded declares an inner generic package, versus itself being directly a generic child of Strings, in order to retain compatibility with a version of the string-handling packages that is generic with respect to the character and string types.

1.b **Reason:** The bound of a bounded-length string is specified as a parameter to a generic, versus as the value for a discriminant, because of the inappropriateness of assignment and equality of discriminated types for the copying and comparison of bounded strings.

Static Semantics

The library package Strings.Bounded has the following declaration: 2

```
{AI12-0241-1} {AI12-0302-1} with Ada.Strings.Maps;                                    3/5

```

This paragraph was deleted.{*8652/0097*} {*AI95-00115-01*} {*AI95-00344-01*} 82.a.1/2

Null_Bounded_String represents the null string. If an object of type Bounded_String is not otherwise initialized, it will be initialized to the same value as Null_Bounded_String. 83

```
function Length (Source : in Bounded_String) return Length_Range;                  84
```

The Length function returns the length of the string represented by Source. 85

86
```
function To_Bounded_String (Source : in String;
                            Drop   : in Truncation := Error)
   return Bounded_String;
```

87/3 {*AI05-0264-1*} If Source'Length <= Max_Length, then this function returns a Bounded_String that represents Source. Otherwise, the effect depends on the value of Drop:

88 • If Drop=Left, then the result is a Bounded_String that represents the string comprising the rightmost Max_Length characters of Source.

89 • If Drop=Right, then the result is a Bounded_String that represents the string comprising the leftmost Max_Length characters of Source.

90 • If Drop=Error, then Strings.Length_Error is propagated.

91
```
function To_String (Source : in Bounded_String) return String;
```

92 To_String returns the String value with lower bound 1 represented by Source. If B is a Bounded_String, then B = To_Bounded_String(To_String(B)).

92.1/2
```
procedure Set_Bounded_String
   (Target :    out Bounded_String;
    Source : in     String;
    Drop   : in     Truncation := Error);
```

92.2/2 {*AI95-00301-01*} Equivalent to Target := To_Bounded_String (Source, Drop);

93 Each of the Append functions returns a Bounded_String obtained by concatenating the string or character given or represented by one of the parameters, with the string or character given or represented by the other parameter, and applying To_Bounded_String to the concatenation result string, with Drop as provided to the Append function.

94 Each of the procedures Append(Source, New_Item, Drop) has the same effect as the corresponding assignment Source := Append(Source, New_Item, Drop).

95 Each of the "&" functions has the same effect as the corresponding Append function, with Error as the Drop parameter.

96
```
function Element (Source : in Bounded_String;
                  Index  : in Positive)
   return Character;
```

97 Returns the character at position Index in the string represented by Source; propagates Index_Error if Index > Length(Source).

98
```
procedure Replace_Element (Source : in out Bounded_String;
                           Index  : in Positive;
                           By     : in Character);
```

99 Updates Source such that the character at position Index in the string represented by Source is By; propagates Index_Error if Index > Length(Source).

100
```
function Slice (Source : in Bounded_String;
                Low    : in Positive;
                High   : in Natural)
   return String;
```

101/1 {*8652/0049*} {*AI95-00128-01*} {*AI95-00238-01*} Returns the slice at positions Low through High in the string represented by Source; propagates Index_Error if Low > Length(Source)+1 or High > Length(Source). The bounds of the returned string are Low and High.

```
function Bounded_Slice                                                    101.1/2
   (Source : in Bounded_String;
    Low    : in Positive;
    High   : in Natural)
      return Bounded_String;
```

{*AI95-00301-01*} Returns the slice at positions Low through High in the string represented by Source as a bounded string; propagates Index_Error if Low > Length(Source)+1 or High > Length(Source). 101.2/2

```
procedure Bounded_Slice                                                   101.3/2
   (Source : in     Bounded_String;
    Target :    out Bounded_String;
    Low    : in     Positive;
    High   : in     Natural);
```

{*AI95-00301-01*} Equivalent to Target := Bounded_Slice (Source, Low, High); 101.4/2

Each of the functions "=", "<", ">", "<=", and ">=" returns the same result as the corresponding String operation applied to the String values given or represented by the two parameters. 102

Each of the search subprograms (Index, Index_Non_Blank, Count, Find_Token) has the same effect as the corresponding subprogram in Strings.Fixed applied to the string represented by the Bounded_String parameter. 103

Each of the Translate subprograms, when applied to a Bounded_String, has an analogous effect to the corresponding subprogram in Strings.Fixed. For the Translate function, the translation is applied to the string represented by the Bounded_String parameter, and the result is converted (via To_Bounded_String) to a Bounded_String. For the Translate procedure, the string represented by the Bounded_String parameter after the translation is given by the Translate function for fixed-length strings applied to the string represented by the original value of the parameter. 104

{*8652/0049*} {*AI95-00128-01*} Each of the transformation subprograms (Replace_Slice, Insert, Overwrite, Delete), selector subprograms (Trim, Head, Tail), and constructor functions ("*") has an effect based on its corresponding subprogram in Strings.Fixed, and Replicate is based on Fixed."*". In the case of a function, the corresponding fixed-length string subprogram is applied to the string represented by the Bounded_String parameter. To_Bounded_String is applied the result string, with Drop (or Error in the case of Generic_Bounded_Length."*") determining the effect when the string length exceeds Max_Length. In the case of a procedure, the corresponding function in Strings.Bounded.Generic_-Bounded_Length is applied, with the result assigned into the Source parameter. 105/1

Ramification: {*AI95-00114-01*} The "/=" operations between Bounded_String and String, and between String and Bounded_String, are automatically defined based on the corresponding "=" operations. 105.a/2

Implementation Advice

Bounded string objects should not be implemented by implicit pointers and dynamic allocation. 106

Implementation Advice: Bounded string objects should not be implemented by implicit pointers and dynamic allocation. 106.a.1/2

Implementation Note: The following is a possible implementation of the private part of the package: 106.a

```
type Bounded_String_Internals (Length : Length_Range := 0) is             106.b
   record
      Data : String(1..Length);
   end record;

type Bounded_String is                                                    106.c
   record
      Data : Bounded_String_Internals;  -- Unconstrained
   end record;
```

106.d
```
Null_Bounded_String : constant Bounded_String :=
   (Data => (Length => 0,
             Data   => (1..0 => ' ')));
```

Inconsistencies With Ada 95

106.e/2 {*AI95-00238-01*} **Amendment Correction:** The bounds of the string returned from Slice are now defined. This is technically an inconsistency; if a program depended on some other lower bound for the string returned from Slice, it could fail when compiled with Ada 2005. Such code is not portable even between Ada 95 implementations, so it should be very rare.

Incompatibilities With Ada 95

106.f/3 {*AI95-00301-01*} {*AI05-0005-1*} Procedure Set_Bounded_String, two Bounded_Slice subprograms, and overloaded versions of Index and Index_Non_Blank are added to Strings.Bounded.Generic_Bounded_Length. If an instance of Generic_Bounded_Length is referenced in a use_clause, and an entity *E* with the defining_identifier as a new entity in Generic_Bounded_Length is defined in a package that is also referenced in a use_clause, the entity *E* may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur.

Wording Changes from Ada 95

106.g/2 {*8652/0049*} {*AI95-00128-01*} **Corrigendum:** Corrected the conditions for which Slice raises Index_Error.

106.h/2 {*8652/0049*} {*AI95-00128-01*} **Corrigendum:** Clarified the meaning of transformation, selector, and constructor subprograms by describing the effects of procedures and functions separately.

Incompatibilities With Ada 2005

106.i/3 {*AI05-0031-1*} An overloaded version of Find_Token is added to Strings.Bounded.Generic_Bounded_Length. If an instance of Generic_Bounded_Length is referenced in a use_clause, and an entity *E* with a defining_identifier of Find_Token is defined in a package that is also referenced in a use_clause, the entity *E* may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur.

A.4.5 Unbounded-Length String Handling

1/5 {*AI12-0445-1*} The language-defined package Strings.Unbounded provides a private type Unbounded_String and a set of operations. An object of type Unbounded_String represents a String whose low bound is 1 and whose length can vary conceptually between 0 and Natural'Last. The subprograms for fixed-length string handling are either overloaded directly for Unbounded_String, or are modified as necessary to reflect the flexibility in length. Since the Unbounded_String type is private, relevant constructor and selector operations are provided.

1.a **Reason:** The transformation operations for fixed- and bounded-length strings that are not necessarily length preserving are supplied for Unbounded_String as procedures as well as functions. This allows an implementation to do an initial allocation for an unbounded string and to avoid further allocations as long as the length does not exceed the allocated length.

Static Semantics

2 The library package Strings.Unbounded has the following declaration:

3/5
```
{AI12-0241-1} {AI12-0302-1} with Ada.Strings.Maps;
package Ada.Strings.Unbounded
   with Preelaborate, Nonblocking, Global => in out synchronized is
```

4/5
```
   {AI95-00161-01} {AI12-0399-1}    type Unbounded_String is private
         with Preelaborable_Initialization;
```

5
```
   Null_Unbounded_String : constant Unbounded_String;
```

6
```
   function Length (Source : in Unbounded_String) return Natural;
```

7
```
   type String_Access is access all String;
   procedure Free (X : in out String_Access);
```

8
```
   -- Conversion, Concatenation, and Selection functions
```

9
```
   function To_Unbounded_String (Source : in String)
      return Unbounded_String;
```

```
   function To_Unbounded_String (Length : in Natural)                                  10
      return Unbounded_String;

69          function "*" (Left  : in Natural;
                          Right : in Character)
               return Unbounded_String;

70          function "*" (Left  : in Natural;
                          Right : in String)
               return Unbounded_String;

71          function "*" (Left  : in Natural;
                          Right : in Unbounded_String)
               return Unbounded_String;

72       private
            ... -- not specified by the language
         end Ada.Strings.Unbounded;
```

72.1/2 {*AI95-00360-01*} The type Unbounded_String needs finalization (see 7.6).

73 Null_Unbounded_String represents the null String. If an object of type Unbounded_String is not otherwise initialized, it will be initialized to the same value as Null_Unbounded_String.

74 The function Length returns the length of the String represented by Source.

75 The type String_Access provides a (nonprivate) access type for explicit processing of unbounded-length strings. The procedure Free performs an unchecked deallocation of an object of type String_Access.

76 The function To_Unbounded_String(Source : in String) returns an Unbounded_String that represents Source. The function To_Unbounded_String(Length : in Natural) returns an Unbounded_String that represents an uninitialized String whose length is Length.

77 The function To_String returns the String with lower bound 1 represented by Source. To_String and To_Unbounded_String are related as follows:

78 • If S is a String, then To_String(To_Unbounded_String(S)) = S.

- If U is an Unbounded_String, then To_Unbounded_String(To_String(U)) = U. 79

{*AI95-00301-01*} The procedure Set_Unbounded_String sets Target to an Unbounded_String that represents Source. 79.1/2

For each of the Append procedures, the resulting string represented by the Source parameter is given by the concatenation of the original value of Source and the value of New_Item. 80

Each of the "&" functions returns an Unbounded_String obtained by concatenating the string or character given or represented by one of the parameters, with the string or character given or represented by the other parameter, and applying To_Unbounded_String to the concatenation result string. 81

Ramification: {*AI12-0005-1*} If the resulting string is longer than Natural'Last, Constraint_Error is raised because the upper bound of the underlying String concatenation is outside of the range of the index subtype of Natural (see 4.5.3). Note that the same is true for other operations that attempt to create an overlong string: either they are defined in terms of this concatenation operation (as with Append) or they are defined in terms of Ada.Strings.Fixed operations (as with Insert and Replace_Slice), which themselves are defined in terms of String concatenation (which raises Constraint_Error for overlong strings as described above). Therefore, it is never possible to create an Unbounded_String with a length greater than Natural'Last. 81.a/5

The Element, Replace_Element, and Slice subprograms have the same effect as the corresponding bounded-length string subprograms. 82

{*AI95-00301-01*} {*AI05-0262-1*} The function Unbounded_Slice returns the slice at positions Low through High in the string represented by Source as an Unbounded_String. The procedure Unbounded_Slice sets Target to the Unbounded_String representing the slice at positions Low through High in the string represented by Source. Both subprograms propagate Index_Error if Low > Length(Source)+1 or High > Length(Source). 82.1/3

Each of the functions "=", "<", ">", "<=", and ">=" returns the same result as the corresponding String operation applied to the String values given or represented by Left and Right. 83

Each of the search subprograms (Index, Index_Non_Blank, Count, Find_Token) has the same effect as the corresponding subprogram in Strings.Fixed applied to the string represented by the Unbounded_String parameter. 84

The Translate function has an analogous effect to the corresponding subprogram in Strings.Fixed. The translation is applied to the string represented by the Unbounded_String parameter, and the result is converted (via To_Unbounded_String) to an Unbounded_String. 85

Each of the transformation functions (Replace_Slice, Insert, Overwrite, Delete), selector functions (Trim, Head, Tail), and constructor functions ("*") is likewise analogous to its corresponding subprogram in Strings.Fixed. For each of the subprograms, the corresponding fixed-length string subprogram is applied to the string represented by the Unbounded_String parameter, and To_Unbounded_String is applied the result string. 86

For each of the procedures Translate, Replace_Slice, Insert, Overwrite, Delete, Trim, Head, and Tail, the resulting string represented by the Source parameter is given by the corresponding function for fixed-length strings applied to the string represented by Source's original value. 87

Implementation Requirements

No storage associated with an Unbounded_String object shall be lost upon assignment or scope exit. 88

Implementation Note: {*AI95-00301-01*} A sample implementation of the private part of the package and several of the subprograms appears in the Ada 95 Rationale. 88.a/2

Incompatibilities With Ada 95

88.b/2 {*AI95-00360-01*} **Amendment Correction:** Type Unbounded_String is defined to need finalization. If the restriction No_Nested_Finalization (see D.7) applies to the partition, and Unbounded_String does not have a controlled part, it will not be allowed in local objects in Ada 2005 whereas it would be allowed in original Ada 95. Such code is not portable, as most Ada compilers have a controlled part in Unbounded_String, and thus would be illegal.

88.c/3 {*AI95-00301-01*} {*AI05-0005-1*} Procedure Set_Unbounded_String, two Unbounded_Slice subprograms, and overloaded versions of Index and Index_Non_Blank are added to Strings.Unbounded. If Strings.Unbounded is referenced in a use_clause, and an entity *E* with the same defining_identifier as a new entity in Strings.Unbounded is defined in a package that is also referenced in a use_clause, the entity *E* may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur.

Extensions to Ada 95

88.d/2 {*AI95-00161-01*} **Amendment Correction:** Added a pragma Preelaborable_Initialization to type Unbounded_String, so that it can be used to declare default-initialized objects in preelaborated units.

Incompatibilities With Ada 2005

88.e/3 {*AI05-0031-1*} An overloaded version of Find_Token is added to Strings.Unbounded. If Strings.Unbounded is referenced in a use_clause, and an entity *E* with a defining_identifier of Find_Token is defined in a package that is also referenced in a use_clause, the entity *E* may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur.

A.4.6 String-Handling Sets and Mappings

1 The language-defined package Strings.Maps.Constants declares Character_Set and Character_Mapping constants corresponding to classification and conversion functions in package Characters.Handling.

1.a **Discussion:** The Constants package is a child of Strings.Maps since it needs visibility of the private part of Strings.Maps in order to initialize the constants in a preelaborable way (i.e. via aggregates versus function calls).

Static Semantics

2 The library package Strings.Maps.Constants has the following declaration:

3/5
```
{AI95-00362-01} {AI12-0414-1} package Ada.Strings.Maps.Constants
   with Pure is

4     Control_Set           : constant Character_Set;
      Graphic_Set           : constant Character_Set;
      Letter_Set            : constant Character_Set;
      Lower_Set             : constant Character_Set;
      Upper_Set             : constant Character_Set;
      Basic_Set             : constant Character_Set;
      Decimal_Digit_Set     : constant Character_Set;
      Hexadecimal_Digit_Set : constant Character_Set;
      Alphanumeric_Set      : constant Character_Set;
      Special_Set           : constant Character_Set;
      ISO_646_Set           : constant Character_Set;

5     Lower_Case_Map        : constant Character_Mapping;
        --Maps to lower case for letters, else identity
      Upper_Case_Map        : constant Character_Mapping;
        --Maps to upper case for letters, else identity
      Basic_Map             : constant Character_Mapping;
        --Maps to basic letter for letters, else identity

6  private
      ... -- not specified by the language
   end Ada.Strings.Maps.Constants;
```

7 Each of these constants represents a correspondingly named set of characters or character mapping in Characters.Handling (see A.3.2).

8/5 NOTE {*AI05-0114-1*} {*AI12-0450-1*} There are certain characters which are defined to be lower case letters by ISO/IEC 10646 and are therefore allowed in identifiers, but are not considered lower case letters by Ada.Strings.Maps.Constants.

Reason: This is to maintain runtime compatibility with the Ada 95 definitions of these constants; existing correct programs could break if the definitions were changed in a way the programs did not anticipate. 8.a/3

Extensions to Ada 95

{*AI95-00362-01*} Strings.Maps.Constants is now Pure, so it can be used in pure units. 8.b/2

Wording Changes from Ada 2005

{*AI05-0114-1*} **Correction:** Added a note to clarify that these constants don't have any relationship to the characters allowed in identifiers. 8.c/3

A.4.7 Wide_String Handling

{*AI95-00302-03*} {*AI05-0286-1*} Facilities for handling strings of Wide_Character elements are found in the packages Strings.Wide_Maps, Strings.Wide_Fixed, Strings.Wide_Bounded, Strings.Wide_-Unbounded, and Strings.Wide_Maps.Wide_Constants, and in the library functions Strings.Wide_Hash, Strings.Wide_Fixed.Wide_Hash, Strings.Wide_Bounded.Wide_Hash, Strings.Wide_Unbounded.-Wide_Hash, Strings.Wide_Hash_Case_Insensitive, Strings.Wide_Fixed.Wide_Hash_Case_Insensitive, Strings.Wide_Bounded.Wide_Hash_Case_Insensitive, Strings.Wide_Unbounded.Wide_Hash_Case_-Insensitive, Strings.Wide_Equal_Case_Insensitive, Strings.Wide_Fixed.Wide_Equal_Case_Insensitive, Strings.Wide_Bounded.Wide_Equal_Case_Insensitive, and Strings.Wide_Unbounded.Wide_Equal_-Case_Insensitive. They provide the same string-handling operations as the corresponding packages and functions for strings of Character elements. 1/3

Static Semantics

The package Strings.Wide_Maps has the following declaration. 2

```
{AI12-0241-1} {AI12-0302-1} package Ada.Strings.Wide_Maps                                   3/5
   with Preelaborate, Nonblocking, Global => in out synchronized is
{AI95-00161-01} {AI12-0399-1}     -- Representation for a set of Wide_Character values:    4/5
   type Wide_Character_Set is private
      with Preelaborable_Initialization;
   Null_Set : constant Wide_Character_Set;                                                  5
   type Wide_Character_Range is                                                             6
     record
         Low  : Wide_Character;
         High : Wide_Character;
     end record;
   -- Represents Wide_Character range Low..High
   type Wide_Character_Ranges is array (Positive range <>)                                  7
      of Wide_Character_Range;
   function To_Set    (Ranges : in Wide_Character_Ranges)                                   8
      return Wide_Character_Set;
   function To_Set    (Span   : in Wide_Character_Range)                                    9
      return Wide_Character_Set;
   function To_Ranges (Set    : in Wide_Character_Set)                                      10
      return Wide_Character_Ranges;
   function "="   (Left, Right : in Wide_Character_Set) return Boolean;                     11
```

```
12          function "not" (Right : in Wide_Character_Set)
               return Wide_Character_Set;
            function "and" (Left, Right : in Wide_Character_Set)

               return Wide_Character_Set;
            function "xor" (Left, Right : in Wide_Character_Set)
               return Wide_Character_Set;
            function "-"   (Left, Right : in Wide_Character_Set)
               return Wide_Character_Set;
13          function Is_In (Element : in Wide_Character;
                            Set     : in Wide_Character_Set)
               return Boolean;
14          function Is_Subset (Elements : in Wide_Character_Set;
                                Set      : in Wide_Character_Set)
               return Boolean;
15          function "<=" (Left  : in Wide_Character_Set;
                           Right : in Wide_Character_Set)
               return Boolean renames Is_Subset;
16          -- Alternative representation for a set of Wide_Character values:
            subtype Wide_Character_Sequence is Wide_String;
17          function To_Set (Sequence  : in Wide_Character_Sequence)
               return Wide_Character_Set;
18          function To_Set (Singleton : in Wide_Character)
               return Wide_Character_Set;
19          function To_Sequence (Set  : in Wide_Character_Set)
               return Wide_Character_Sequence;
20/5     {AI95-00161-01} {AI12-0399-1}     -- Representation for a Wide_Character to Wide_Character mapping:
            type Wide_Character_Mapping is private
                with Preelaborable_Initialization;
21          function Value (Map     : in Wide_Character_Mapping;
                            Element : in Wide_Character)
               return Wide_Character;
22          Identity : constant Wide_Character_Mapping;
23          function To_Mapping (From, To : in Wide_Character_Sequence)
               return Wide_Character_Mapping;
24          function To_Domain (Map : in Wide_Character_Mapping)
               return Wide_Character_Sequence;
25          function To_Range  (Map : in Wide_Character_Mapping)
               return Wide_Character_Sequence;
26          type Wide_Character_Mapping_Function is
               access function (From : in Wide_Character) return Wide_Character;
27       private
            ... -- not specified by the language
         end Ada.Strings.Wide_Maps;
```

28 The context clause for each of the packages Strings.Wide_Fixed, Strings.Wide_Bounded, and Strings.Wide_Unbounded identifies Strings.Wide_Maps instead of Strings.Maps.

28.1/3 {*AI05-0223-1*} Types Wide_Character_Set and Wide_Character_Mapping need finalization.

29/3 {*AI95-00302-03*} {*AI05-0286-1*} For each of the packages Strings.Fixed, Strings.Bounded, Strings.Unbounded, and Strings.Maps.Constants, and for library functions Strings.Hash, Strings.Fixed.Hash, Strings.Bounded.Hash, Strings.Unbounded.Hash, Strings.Hash_Case_Insensitive, Strings.Fixed.Hash_Case_Insensitive, Strings.Bounded.Hash_Case_Insensitive, Strings.-Unbounded.Hash_Case_Insensitive, Strings.Equal_Case_Insensitive, Strings.Fixed.Equal_Case_-

Insensitive, Strings.Bounded.Equal_Case_Insensitive, and Strings.Unbounded.Equal_Case_Insensitive, the corresponding wide string package or function has the same contents except that

- Wide_Space replaces Space 30
- Wide_Character replaces Character 31
- Wide_String replaces String 32
- Wide_Character_Set replaces Character_Set 33
- Wide_Character_Mapping replaces Character_Mapping 34
- Wide_Character_Mapping_Function replaces Character_Mapping_Function 35
- Wide_Maps replaces Maps 36
- Bounded_Wide_String replaces Bounded_String 37
- Null_Bounded_Wide_String replaces Null_Bounded_String 38
- To_Bounded_Wide_String replaces To_Bounded_String 39
- To_Wide_String replaces To_String 40
- {*AI95-00301-01*} Set_Bounded_Wide_String replaces Set_Bounded_String 40.1/2
- Unbounded_Wide_String replaces Unbounded_String 41
- Null_Unbounded_Wide_String replaces Null_Unbounded_String 42
- Wide_String_Access replaces String_Access 43
- To_Unbounded_Wide_String replaces To_Unbounded_String 44
- {*AI95-00301-01*} Set_Unbounded_Wide_String replaces Set_Unbounded_String 44.1/2

The following additional declaration is present in Strings.Wide_Maps.Wide_Constants: 45

```
{AI95-00285-01} {AI95-00395-01} Character_Set : constant
Wide_Maps.Wide_Character_Set;
--Contains each Wide_Character value WC such that
--Characters.Conversions.Is_Character(WC) is True
```
46/2

{*AI95-00395-01*} Each Wide_Character_Set constant in the package Strings.Wide_Maps.Wide_Constants contains no values outside the Character portion of Wide_Character. Similarly, each Wide_Character_Mapping constant in this package is the identity mapping when applied to any element outside the Character portion of Wide_Character. 46.1/2

{*AI95-00362-01*} {*AI12-0302-1*} {*AI12-0414-1*} Aspect Pure is replaced by aspects `Preelaborate, Nonblocking, Global => in out synchronized` in Strings.Wide_Maps.Wide_Constants. 47/5

NOTE If a null Wide_Character_Mapping_Function is passed to any of the Wide_String handling subprograms, Constraint_Error is propagated. 48/5

Incompatibilities With Ada 95

{*AI95-00301-01*} Various new operations are added to Strings.Wide_Fixed, Strings.Wide_Bounded, and Strings.Wide_Unbounded. If one of these packages is referenced in a use_clause, and an entity *E* with the same defining_identifier as a new entity is defined in a package that is also referenced in a use_clause, the entity *E* may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur. 49.a/2

Extensions to Ada 95

{*AI95-00161-01*} **Amendment Correction:** Added pragma Preelaborable_Initialization to types Wide_Character_Set and Wide_Character_Mapping, so that they can be used to declare default-initialized objects in preelaborated units. 49.b/2

Wording Changes from Ada 95

{*AI95-00285-01*} Corrected the description of Character_Set. 49.c/2

49.d/2 {*AI95-00302-03*} Added wide versions of Strings.Hash and Strings.Unbounded.Hash.

49.e/2 {*AI95-00362-01*} Added wording so that Strings.Wide_Maps.Wide_Constants does not change to Pure.

49.f/2 {*AI95-00395-01*} The second Note is now normative text, since there is no way to derive it from the other rules. It's a little weird given the use of Unicode character classifications in Ada 2005; but changing it would be inconsistent with Ada 95 and a one-to-one mapping isn't necessarily correct anyway.

Extensions to Ada 2005

49.g/3 {*AI05-0286-1*} The case insenstive library functions (Strings.Wide_Equal_Case_Insensitive, Strings.Wide_-Fixed.Wide_Equal_Case_Insensitive, Strings.Wide_Bounded.Wide_Equal_Case_Insensitive, Strings.Wide_-Unbounded.Wide_Equal_Case_Insensitive, Strings.Wide_Hash_Case_Insensitive, Strings.Wide_Fixed.Wide_Hash_-Case_Insensitive, Strings.Wide_Bounded.Wide_Hash_Case_Insensitive, and Strings.Wide_Unbounded.Wide_Hash_-Case_Insensitive) are new.

Wording Changes from Ada 2005

49.h/3 {*AI05-0223-1*} **Correction**: Identified Wide_Character_Set and Wide_Character_Mapping as needing finalization. It is likely that they are implemented with a controlled type, so this change is unlikely to make any difference in practice.

A.4.8 Wide_Wide_String Handling

1/3 {*AI95-00285-01*} {*AI95-00395-01*} {*AI05-0286-1*} Facilities for handling strings of Wide_Wide_Character elements are found in the packages Strings.Wide_Wide_Maps, Strings.-Wide_Wide_Fixed, Strings.Wide_Wide_Bounded, Strings.Wide_Wide_Unbounded, and Strings.-Wide_Wide_Maps.Wide_Wide_Constants, and in the library functions Strings.Wide_Wide_Hash, Strings.Wide_Wide_Fixed.Wide_Wide_Hash, Strings.Wide_Wide_Bounded.Wide_Wide_Hash, Strings.-Wide_Wide_Unbounded.Wide_Wide_Hash, Strings.Wide_Wide_Hash_Case_Insensitive, Strings.-Wide_Wide_Fixed.Wide_Wide_Hash_Case_Insensitive, Strings.Wide_Wide_Bounded.Wide_Wide_-Hash_Case_Insensitive, Strings.Wide_Wide_Unbounded.Wide_Wide_Hash_Case_Insensitive, Strings.-Wide_Wide_Equal_Case_Insensitive, Strings.Wide_Wide_Fixed.Wide_Wide_Equal_Case_Insensitive, Strings.Wide_Wide_Bounded.Wide_Wide_Equal_Case_Insensitive, and Strings.Wide_Wide_-Unbounded.Wide_Wide_Equal_Case_Insensitive. They provide the same string-handling operations as the corresponding packages and functions for strings of Character elements.

Static Semantics

2/2 {*AI95-00285-01*} The library package Strings.Wide_Wide_Maps has the following declaration.

```
3/5    {AI12-0241-1} {AI12-0302-1} package Ada.Strings.Wide_Wide_Maps
          with Preelaborate, Nonblocking, Global => in out synchronized is

4/5    {AI12-0399-1}     -- Representation for a set of Wide_Wide_Character values:

Extensions to Ada 95

51.a/2 {*AI95-00285-01*} {*AI95-00395-01*} The double-wide string-handling packages (Strings.Wide_Wide_Maps, Strings.Wide_Wide_Fixed, Strings.Wide_Wide_Bounded, Strings.Wide_Wide_Unbounded, and Strings.Wide_Wide_Maps.Wide_Wide_Constants), and functions Strings.Wide_Wide_Hash and Strings.Wide_Wide_Unbounded.Wide_Wide_Hash are new.

Extensions to Ada 2005

{*AI05-0286-1*} The case insenstive library functions (Strings.Wide_Wide_Equal_Case_Insensitive, Strings.Wide_Wide_Fixed.Wide_Wide_Equal_Case_Insensitive, Strings.Wide_Wide_Bounded.Wide_Wide_Equal_-Case_Insensitive, Strings.Wide_Wide_Unbounded.Wide_Wide_Equal_Case_Insensitive, Strings.Wide_Wide_Hash_-Case_Insensitive, Strings.Wide_Wide_Fixed.Wide_Wide_Hash_Case_Insensitive, Strings.Wide_Wide_-Bounded.Wide_Wide_Hash_Case_Insensitive, and Strings.Wide_Wide_Unbounded.Wide_Wide_Hash_Case_-Insensitive) are new. 51.b/3

Wording Changes from Ada 2005

{*AI05-0223-1*} **Correction**: Identified Wide_Wide_Character_Set and Wide_Wide_Character_Mapping as needing finalization. It is likely that they are implemented with a controlled type, so this change is unlikely to make any difference in practice. 51.c/3

A.4.9 String Hashing

Static Semantics

{*AI95-00302-03*} The library function Strings.Hash has the following declaration: 1/2

```
{AI05-0298-1} {AI12-0414-1} with Ada.Containers;                                    2/5
function Ada.Strings.Hash (Key : String) return Containers.Hash_Type
   with Pure;
```

Returns an implementation-defined value which is a function of the value of Key. If *A* and *B* are strings such that *A* equals *B*, Hash(*A*) equals Hash(*B*). 3/2

Implementation defined: The values returned by Strings.Hash. 3.a/2

{*AI95-00302-03*} The library function Strings.Fixed.Hash has the following declaration: 4/2

```
{AI05-0298-1} with Ada.Containers, Ada.Strings.Hash;                                5/3
function Ada.Strings.Fixed.Hash (Key : String) return Containers.Hash_Type
   renames Ada.Strings.Hash;
```

{*AI95-00302-03*} The generic library function Strings.Bounded.Hash has the following declaration: 6/2

```
{AI05-0298-1} {AI12-0241-1} {AI12-0302-1} with Ada.Containers;                      7/5
generic
   with package Bounded is
      new Ada.Strings.Bounded.Generic_Bounded_Length (<>);
function Ada.Strings.Bounded.Hash (Key : Bounded.Bounded_String)
   return Containers.Hash_Type
   with Preelaborate, Nonblocking, Global => in out synchronized;
```

{*AI05-0001-1*} Equivalent to Strings.Hash (Bounded.To_String (Key)); 8/3

{*AI95-00302-03*} The library function Strings.Unbounded.Hash has the following declaration: 9/2

```
{AI05-0298-1} {AI12-0241-1} {AI12-0302-1} with Ada.Containers;                      10/5
function Ada.Strings.Unbounded.Hash (Key : Unbounded_String)
   return Containers.Hash_Type
   with Preelaborate, Nonblocking, Global => in out synchronized;
```

{*AI05-0001-1*} Equivalent to Strings.Hash (To_String (Key)); 11/3

{*AI05-0001-1*} {*AI05-0298-1*} The library function Strings.Hash_Case_Insensitive has the following declaration: 11.1/3

```
{AI12-0414-1} with Ada.Containers;                                                  11.2/5
function Ada.Strings.Hash_Case_Insensitive (Key : String)
   return Containers.Hash_Type
   with Pure;
```

Returns an implementation-defined value which is a function of the value of Key, converted to lower case. If A and B are strings such that Strings.Equal_Case_Insensitive (A, B) (see A.4.10) is True, then Hash_Case_Insensitive(A) equals Hash_Case_Insensitive(B). 11.3/3

11.4/3 {*AI05-0001-1*} {*AI05-0298-1*} The library function Strings.Fixed.Hash_Case_Insensitive has the following declaration:

11.5/3
```
with Ada.Containers, Ada.Strings.Hash_Case_Insensitive;
function Ada.Strings.Fixed.Hash_Case_Insensitive (Key : String)
   return Containers.Hash_Type renames Ada.Strings.Hash_Case_Insensitive;
```

11.6/3 {*AI05-0001-1*} {*AI05-0298-1*} The generic library function Strings.Bounded.Hash_Case_Insensitive has the following declaration:

11.7/5
```
{AI12-0241-1} {AI12-0302-1} with Ada.Containers;
generic
   with package Bounded is
      new Ada.Strings.Bounded.Generic_Bounded_Length (<>);
function Ada.Strings.Bounded.Hash_Case_Insensitive
   (Key : Bounded.Bounded_String) return Containers.Hash_Type
   with Preelaborate, Nonblocking, Global => in out synchronized;
```

11.8/3 Equivalent to Strings.Hash_Case_Insensitive (Bounded.To_String (Key));

11.9/3 {*AI05-0001-1*} {*AI05-0298-1*} The library function Strings.Unbounded.Hash_Case_Insensitive has the following declaration:

11.10/5
```
{AI12-0241-1} {AI12-0302-1} with Ada.Containers;
function Ada.Strings.Unbounded.Hash_Case_Insensitive
   (Key : Unbounded_String) return Containers.Hash_Type
   with Preelaborate, Nonblocking, Global => in out synchronized;
```

11.11/3 Equivalent to Strings.Hash_Case_Insensitive (To_String (Key));

Implementation Advice

12/2 {*AI95-00302-03*} The Hash functions should be good hash functions, returning a wide spread of values for different string values. It should be unlikely for similar strings to return the same value.

12.a/2 **Implementation Advice:** Strings.Hash should be good a hash function, returning a wide spread of values for different string values, and similar strings should rarely return the same value.

12.b/2 **Ramification:** The other functions are defined in terms of Strings.Hash, so they don't need separate advice in the Annex.

Extensions to Ada 95

12.c/2 {*AI95-00302-03*} The Strings.Hash, Strings.Fixed.Hash, Strings.Bounded.Hash, and Strings.Unbounded.Hash functions are new.

Extensions to Ada 2005

12.d/3 {*AI05-0001-1*} The Strings.Hash_Case_Insensitive, Strings.Fixed.Hash_Case_Insensitive, Strings.Bounded.Hash_Case_Insensitive, and Strings.Unbounded.Hash_Case_Insensitive functions are new.

A.4.10 String Comparison

Static Semantics

1/3 {*AI05-0001-1*} {*AI05-0286-1*} {*AI05-0298-1*} The library function Strings.Equal_Case_Insensitive has the following declaration:

2/5
```
{AI12-0414-1} function Ada.Strings.Equal_Case_Insensitive (Left, Right : String)
   return Boolean with Pure;
```

3/5 {*AI12-0263-1*} {*AI12-0450-1*} Returns True if the strings consist of the same sequence of characters after applying locale-independent simple case folding, as defined by documents referenced in Clause 2 of ISO/IEC 10646:2020. Otherwise, returns False. This function uses the same method as is used to determine whether two identifiers are the same.

Discussion: {*AI05-0286-1*} For String, this is equivalent to converting to lower case and comparing. Not so for other string types. For Wide_Strings and Wide_Wide_Strings, note that this result is a more accurate comparison than converting the strings to lower case and comparing the results; it is possible that the lower case conversions are the same but this routine will report the strings as different. Additionally, Unicode says that the result of this function will never change for strings made up solely of defined code points; there is no such guarantee for case conversion to lower case. 3.a/3

{*AI12-0263-1*} The "documents referenced" means Unicode, Chapter 4 (specifically, section 4.2 — Case). See the Implementation Notes in 2.3 for a source for machine-readable definitions of these properties. 3.b/5

{*AI05-0001-1*} {*AI05-0248-1*} {*AI05-0298-1*} The library function Strings.Fixed.Equal_Case_Insensitive has the following declaration: 4/3

```
with Ada.Strings.Equal_Case_Insensitive;                                    5/3
function Ada.Strings.Fixed.Equal_Case_Insensitive
   (Left, Right : String) return Boolean
      renames Ada.Strings.Equal_Case_Insensitive;
```

{*AI05-0001-1*} {*AI05-0248-1*} {*AI05-0298-1*} The generic library function Strings.Bounded.Equal_Case_Insensitive has the following declaration: 6/3

```
{AI12-0241-1} {AI12-0302-1} generic                                         7/5
   with package Bounded is
      new Ada.Strings.Bounded.Generic_Bounded_Length (<>);
function Ada.Strings.Bounded.Equal_Case_Insensitive
   (Left, Right : Bounded.Bounded_String) return Boolean
   with Preelaborate, Nonblocking, Global => in out synchronized;
```

Equivalent to Strings.Equal_Case_Insensitive (Bounded.To_String (Left), Bounded.To_String (Right)); 8/3

{*AI05-0001-1*} {*AI05-0248-1*} {*AI05-0298-1*} The library function Strings.Unbounded.Equal_Case_Insensitive has the following declaration: 9/3

```
{AI12-0241-1} {AI12-0302-1} function Ada.Strings.Unbounded.Equal_Case_Insensitive   10/5
   (Left, Right : Unbounded_String) return Boolean
   with Preelaborate, Nonblocking, Global => in out synchronized;
```

Equivalent to Strings.Equal_Case_Insensitive (To_String (Left), To_String (Right)); 11/3

{*AI05-0001-1*} {*AI05-0298-1*} The library function Strings.Less_Case_Insensitive has the following declaration: 12/3

```
{AI12-0414-1} function Ada.Strings.Less_Case_Insensitive (Left, Right : String)   13/5
   return Boolean with Pure;
```

Performs a lexicographic comparison of strings Left and Right, converted to lower case. 14/3

{*AI05-0001-1*} {*AI05-0248-1*} {*AI05-0298-1*} The library function Strings.Fixed.Less_Case_Insensitive has the following declaration: 15/3

```
with Ada.Strings.Less_Case_Insensitive;                                     16/3
function Ada.Strings.Fixed.Less_Case_Insensitive
   (Left, Right : String) return Boolean
      renames Ada.Strings.Less_Case_Insensitive;
```

{*AI05-0001-1*} {*AI05-0248-1*} {*AI05-0298-1*} The generic library function Strings.Bounded.Less_Case_Insensitive has the following declaration: 17/3

```
{AI12-0241-1} {AI12-0302-1} generic                                         18/5
   with package Bounded is
      new Ada.Strings.Bounded.Generic_Bounded_Length (<>);
function Ada.Strings.Bounded.Less_Case_Insensitive
  (Left, Right : Bounded.Bounded_String) return Boolean
   with Preelaborate, Nonblocking, Global => in out synchronized;
```

Equivalent to Strings.Less_Case_Insensitive (Bounded.To_String (Left), Bounded.To_String (Right)); 19/3

20/3 {*AI05-0001-1*} {*AI05-0248-1*} {*AI05-0298-1*} The library function Strings.Unbounded.Less_Case_Insensitive has the following declaration:

21/5
```
{AI12-0241-1} {AI12-0302-1} function Ada.Strings.Unbounded.Less_Case_Insensitive
  (Left, Right : Unbounded_String) return Boolean
   with Preelaborate, Nonblocking, Global => in out synchronized;
```

22/3 Equivalent to Strings.Less_Case_Insensitive (To_String (Left), To_String (Right));

Extensions to Ada 2005

22.a/3 {*AI05-0001-1*} {*AI05-0286-1*} The Strings.Equal_Case_Insensitive, Strings.Fixed.Equal_Case_Insensitive, Strings.Bounded.Equal_Case_Insensitive, Strings.Unbounded.Equal_Case_Insensitive, Strings.Less_Case_Insensitive, Strings.Fixed.Less_Case_Insensitive, Strings.Bounded.Less_Case_Insensitive, Strings.Unbounded.Less_Case_Insensitive functions are new.

A.4.11 String Encoding

1/3 {*AI05-0137-2*} Facilities for encoding, decoding, and converting strings in various character encoding schemes are provided by packages Strings.UTF_Encoding, Strings.UTF_Encoding.Conversions, Strings.UTF_Encoding.Strings, Strings.UTF_Encoding.Wide_Strings, and Strings.UTF_Encoding.Wide_Wide_Strings.

Static Semantics

2/3 {*AI05-0137-2*} The encoding library packages have the following declarations:

3/5
```
{AI05-0137-2} {AI12-0414-1} package Ada.Strings.UTF_Encoding
  with Pure is
```

4/3
```
   -- Declarations common to the string encoding packages
   type Encoding_Scheme is (UTF_8, UTF_16BE, UTF_16LE);
```

5/3
```
   subtype UTF_String is String;
```

6/3
```
   subtype UTF_8_String is String;
```

7/3
```
   subtype UTF_16_Wide_String is Wide_String;
```

8/3
```
   Encoding_Error : exception;
```

9/3
```
   BOM_8    : constant UTF_8_String :=
                 Character'Val(16#EF#) &
                 Character'Val(16#BB#) &
                 Character'Val(16#BF#);
```

10/3
```
   BOM_16BE : constant UTF_String :=
                 Character'Val(16#FE#) &
                 Character'Val(16#FF#);
```

11/3
```
   BOM_16LE : constant UTF_String :=
                 Character'Val(16#FF#) &
                 Character'Val(16#FE#);
```

12/3
```
   BOM_16   : constant UTF_16_Wide_String :=
                (1 => Wide_Character'Val(16#FEFF#));
```

13/3
```
   function Encoding (Item    : UTF_String;
                      Default : Encoding_Scheme := UTF_8)
      return Encoding_Scheme;
```

14/3
```
end Ada.Strings.UTF_Encoding;
```

15/5
```
{AI05-0137-2} {AI12-0414-1} package Ada.Strings.UTF_Encoding.Conversions
   with Pure is
```

16/3
```
   -- Conversions between various encoding schemes
   function Convert (Item          : UTF_String;
                     Input_Scheme  : Encoding_Scheme;
                     Output_Scheme : Encoding_Scheme;
                     Output_BOM    : Boolean := False) return UTF_String;
```

```
   function Convert (Item          : UTF_String;                                    17/3
                     Input_Scheme  : Encoding_Scheme;
                     Output_BOM    : Boolean := False)
      return UTF_16_Wide_String;

```
      function Decode (Item : UTF_16_Wide_String) return Wide_Wide_String;
```

45/3
```
   end Ada.Strings.UTF_Encoding.Wide_Wide_Strings;
```

46/3 {*AI05-0137-2*} {*AI05-0262-1*} The type Encoding_Scheme defines encoding schemes. UTF_8 corresponds to the UTF-8 encoding scheme defined by Annex D of ISO/IEC 10646. UTF_16BE corresponds to the UTF-16 encoding scheme defined by Annex C of ISO/IEC 10646 in 8 bit, big-endian order; and UTF_16LE corresponds to the UTF-16 encoding scheme in 8 bit, little-endian order.

47/3 {*AI05-0137-2*} The subtype UTF_String is used to represent a String of 8-bit values containing a sequence of values encoded in one of three ways (UTF-8, UTF-16BE, or UTF-16LE). The subtype UTF_8_String is used to represent a String of 8-bit values containing a sequence of values encoded in UTF-8. The subtype UTF_16_Wide_String is used to represent a Wide_String of 16-bit values containing a sequence of values encoded in UTF-16.

48/3 {*AI05-0137-2*} {*AI05-0262-1*} The BOM_8, BOM_16BE, BOM_16LE, and BOM_16 constants correspond to values used at the start of a string to indicate the encoding.

49/3 {*AI05-0262-1*} {*AI05-0269-1*} Each of the Encode functions takes a String, Wide_String, or Wide_Wide_String Item parameter that is assumed to be an array of unencoded characters. Each of the Convert functions takes a UTF_String, UTF_8_String, or UTF_16_String Item parameter that is assumed to contain characters whose position values correspond to a valid encoding sequence according to the encoding scheme required by the function or specified by its Input_Scheme parameter.

50/3 {*AI05-0137-2*} {*AI05-0262-1*} {*AI05-0269-1*} Each of the Convert and Encode functions returns a UTF_String, UTF_8_String, or UTF_16_String value whose characters have position values that correspond to the encoding of the Item parameter according to the encoding scheme required by the function or specified by its Output_Scheme parameter. For UTF_8, no overlong encoding is returned. A BOM is included at the start of the returned string if the Output_BOM parameter is set to True. The lower bound of the returned string is 1.

51/3 {*AI05-0137-2*} {*AI05-0262-1*} Each of the Decode functions takes a UTF_String, UTF_8_String, or UTF_16_String Item parameter which is assumed to contain characters whose position values correspond to a valid encoding sequence according to the encoding scheme required by the function or specified by its Input_Scheme parameter, and returns the corresponding String, Wide_String, or Wide_Wide_String value. The lower bound of the returned string is 1.

52/3 {*AI05-0137-2*} {*AI05-0262-1*} For each of the Convert and Decode functions, an initial BOM in the input that matches the expected encoding scheme is ignored, and a different initial BOM causes Encoding_Error to be propagated.

53/3 {*AI05-0137-2*} The exception Encoding_Error is also propagated in the following situations:

54/4 - {*AI12-0088-1*} By a Convert or Decode function when a UTF encoded string contains an invalid encoding sequence.

54.a/4 **To be honest:** {*AI12-0088-1*} An overlong encoding is not invalid for the purposes of this check, and this does not depend on the character set version in use. Some recent character set standards declare overlong encodings to be invalid; it would be unnecessary and unfriendly to users for Convert or Decode to raise an exception for an overlong encoding.

- {*AI12-0088-1*} By a Convert or Decode function when the expected encoding is UTF-16BE or UTF-16LE and the input string has an odd length. 55/4
- {*AI05-0262-1*} By a Decode function yielding a String when the decoding of a sequence results in a code point whose value exceeds 16#FF#. 56/3
- By a Decode function yielding a Wide_String when the decoding of a sequence results in a code point whose value exceeds 16#FFFF#. 57/3
- {*AI05-0262-1*} By an Encode function taking a Wide_String as input when an invalid character appears in the input. In particular, the characters whose position is in the range 16#D800# .. 16#DFFF# are invalid because they conflict with UTF-16 surrogate encodings, and the characters whose position is 16#FFFE# or 16#FFFF# are also invalid because they conflict with BOM codes. 58/3

{*AI05-0137-2*} 59/3
```
function Encoding (Item    : UTF_String;
                   Default : Encoding_Scheme := UTF_8)
   return Encoding_Scheme;
```

{*AI05-0137-2*} {*AI05-0269-1*} Inspects a UTF_String value to determine whether it starts with a BOM for UTF-8, UTF-16BE, or UTF_16LE. If so, returns the scheme corresponding to the BOM; otherwise, returns the value of Default. 60/3

{*AI05-0137-2*} 61/3
```
function Convert (Item          : UTF_String;
                  Input_Scheme  : Encoding_Scheme;
                  Output_Scheme : Encoding_Scheme;
                  Output_BOM    : Boolean := False) return UTF_String;
```

Returns the value of Item (originally encoded in UTF-8, UTF-16LE, or UTF-16BE as specified by Input_Scheme) encoded in one of these three schemes as specified by Output_Scheme. 62/3

{*AI05-0137-2*} 63/3
```
function Convert (Item          : UTF_String;
                  Input_Scheme  : Encoding_Scheme;
                  Output_BOM    : Boolean := False)
   return UTF_16_Wide_String;
```

Returns the value of Item (originally encoded in UTF-8, UTF-16LE, or UTF-16BE as specified by Input_Scheme) encoded in UTF-16. 64/3

{*AI05-0137-2*} 65/3
```
function Convert (Item          : UTF_8_String;
                  Output_BOM    : Boolean := False)
   return UTF_16_Wide_String;
```

Returns the value of Item (originally encoded in UTF-8) encoded in UTF-16. 66/3

{*AI05-0137-2*} 67/3
```
function Convert (Item          : UTF_16_Wide_String;
                  Output_Scheme : Encoding_Scheme;
                  Output_BOM    : Boolean := False) return UTF_String;
```

Returns the value of Item (originally encoded in UTF-16) encoded in UTF-8, UTF-16LE, or UTF-16BE as specified by Output_Scheme. 68/3

{*AI05-0137-2*} 69/3
```
function Convert (Item          : UTF_16_Wide_String;
                  Output_BOM    : Boolean := False) return UTF_8_String;
```

Returns the value of Item (originally encoded in UTF-16) encoded in UTF-8. 70/3

{*AI05-0137-2*} 71/3
```
function Encode (Item          : String;
                 Output_Scheme : Encoding_Scheme;
                 Output_BOM    : Boolean  := False) return UTF_String;
```

{*AI05-0262-1*} Returns the value of Item encoded in UTF-8, UTF-16LE, or UTF-16BE as specified by Output_Scheme. 72/3

73/3 {*AI05-0137-2*} `function Encode (Item : String; Output_BOM : Boolean := False) return UTF_8_String;`

74/3 Returns the value of Item encoded in UTF-8.

75/3 {*AI05-0137-2*} `function Encode (Item : String; Output_BOM : Boolean := False) return UTF_16_Wide_String;`

76/3 Returns the value of Item encoded in UTF_16.

77/3 {*AI05-0137-2*} `function Decode (Item : UTF_String; Input_Scheme : Encoding_Scheme) return String;`

78/3 Returns the result of decoding Item, which is encoded in UTF-8, UTF-16LE, or UTF-16BE as specified by Input_Scheme.

79/3 {*AI05-0137-2*} `function Decode (Item : UTF_8_String) return String;`

80/3 Returns the result of decoding Item, which is encoded in UTF-8.

81/3 {*AI05-0137-2*} `function Decode (Item : UTF_16_Wide_String) return String;`

82/3 Returns the result of decoding Item, which is encoded in UTF-16.

83/3 {*AI05-0137-2*} `function Encode (Item : Wide_String; Output_Scheme : Encoding_Scheme; Output_BOM : Boolean := False) return UTF_String;`

84/3 {*AI05-0262-1*} Returns the value of Item encoded in UTF-8, UTF-16LE, or UTF-16BE as specified by Output_Scheme.

85/3 {*AI05-0137-2*} `function Encode (Item : Wide_String; Output_BOM : Boolean := False) return UTF_8_String;`

86/3 Returns the value of Item encoded in UTF-8.

87/3 {*AI05-0137-2*} `function Encode (Item : Wide_String; Output_BOM : Boolean := False) return UTF_16_Wide_String;`

88/3 Returns the value of Item encoded in UTF_16.

89/3 {*AI05-0137-2*} `function Decode (Item : UTF_String; Input_Scheme : Encoding_Scheme) return Wide_String;`

90/3 Returns the result of decoding Item, which is encoded in UTF-8, UTF-16LE, or UTF-16BE as specified by Input_Scheme.

91/3 {*AI05-0137-2*} `function Decode (Item : UTF_8_String) return Wide_String;`

92/3 Returns the result of decoding Item, which is encoded in UTF-8.

93/3 {*AI05-0137-2*} `function Decode (Item : UTF_16_Wide_String) return Wide_String;`

94/3 Returns the result of decoding Item, which is encoded in UTF-16.

95/3 {*AI05-0137-2*} `function Encode (Item : Wide_Wide_String; Output_Scheme : Encoding_Scheme; Output_BOM : Boolean := False) return UTF_String;`

96/3 {*AI05-0262-1*} Returns the value of Item encoded in UTF-8, UTF-16LE, or UTF-16BE as specified by Output_Scheme.

97/3 {*AI05-0137-2*} `function Encode (Item : Wide_Wide_String; Output_BOM : Boolean := False) return UTF_8_String;`

98/3 Returns the value of Item encoded in UTF-8.

{*AI05-0137-2*} **function** Encode (Item : Wide_Wide_String; 99/3
Output_BOM : Boolean := False) **return** UTF_16_Wide_String;

Returns the value of Item encoded in UTF_16. 100/3

{*AI05-0137-2*} **function** Decode (Item : UTF_String; 101/3
Input_Scheme : Encoding_Scheme) **return** Wide_Wide_String;

Returns the result of decoding Item, which is encoded in UTF-8, UTF-16LE, or UTF-16BE as specified by Input_Scheme. 102/3

{*AI05-0137-2*} **function** Decode (Item : UTF_8_String) **return** Wide_Wide_String; 103/3

Returns the result of decoding Item, which is encoded in UTF-8. 104/3

{*AI05-0137-2*} **function** Decode (Item : UTF_16_Wide_String) **return** Wide_Wide_String; 105/3

Returns the result of decoding Item, which is encoded in UTF-16. 106/3

Implementation Advice

{*AI05-0137-2*} If an implementation supports other encoding schemes, another similar child of Ada.Strings should be defined. 107/3

Implementation Advice: If an implementation supports other string encoding schemes, a child of Ada.Strings similar to UTF_Encoding should be defined. 107.a.1/3

NOTE {*AI05-0137-2*} A BOM (Byte-Order Mark, code position 16#FEFF#) can be included in a file or other entity to indicate the encoding; it is skipped when decoding. Typically, only the first line of a file or other entity contains a BOM. When decoding, the Encoding function can be called on the first line to determine the encoding; this encoding will then be used in subsequent calls to Decode to convert all of the lines to an internal format. 108/3

Extensions to Ada 2005

{*AI05-0137-2*} The packages Strings.UTF_Encoding, Strings.UTF_Encoding.Conversions, Strings.UTF_Encoding.Strings, Strings.UTF_Encoding.Wide_Strings, and Strings.UTF_Encoding.Wide_Wide_Strings are new. 108.a/3

Wording Changes from Ada 2012

{*AI12-0088-1*} **Corrigendum:** Fixed the omission that Convert routines make the same checks on input as Decode routines. 108.b/4

A.4.12 Universal Text Buffers

{*AI12-0340-1*} {*AI12-0439-1*} A universal text buffer can be used to save and retrieve text of any language-defined string type. The types used to save and retrieve the text can be different. 1/5

Static Semantics

{*AI12-0340-1*} The text buffer library packages have the following declarations: 2/5

```
{AI12-0340-1} {AI12-0384-2} with Ada.Strings.UTF_Encoding.Wide_Wide_Strings;
package Ada.Strings.Text_Buffers
   with Pure is

   type Text_Buffer_Count is range 0 .. implementation-defined;

   New_Line_Count : constant Text_Buffer_Count := implementation-defined;

   type Root_Buffer_Type is abstract tagged private
      with Default_Initial_Condition =>
             Current_Indent (Root_Buffer_Type) = 0;

   function Text_Truncated (Buffer : in Buffer_Type) return Boolean;             28/5

   -- Get, Wide_Get, Wide_Wide_Get, Get_UTF_8, and Wide_Get_UTF_16               29/5
   -- are declared here just as in the Unbounded child.

private                                                                          30/5
   ... -- not specified by the language, but will include nonabstract
       -- overridings of all inherited subprograms that require overriding.
end Ada.Strings.Text_Buffers.Bounded;
```

{*AI12-0340-1*} Character_Count returns the number of characters currently stored in a text buffer. 31/5

Ramification: {*AI12-0340-1*} This is lower-case "characters". The representation isn't considered, so it is irrelevant what type of character (Character, Wide_Character, or Wide_Wide_Character) was stored. 31.a/5

{*AI12-0340-1*} {*AI12-0384-2*} New_Line stores New_Line_Count characters that represent a new line into a text buffer. Current_Indent returns the current indentation associated with the buffer, with zero meaning there is no indentation in effect; Increase_Indent and Decrease_Indent increase or decrease the indentation associated with the buffer. 32/5

{*AI12-0340-1*} {*AI12-0384-2*} A call to Put, Wide_Put, Wide_Wide_Put, Put_UTF_8, or Wide_Put_UTF_16 stores a sequence of characters into the text buffer, preceded by Current_Indent(Buffer) spaces (Wide_Wide_Characters with position 32) if there is at least one character in Item and it would have been the first character on the current line. 33/5

{*AI12-0340-1*} {*AI12-0384-2*} A call to function Get, Wide_Get, Wide_Wide_Get, Get_UTF_8, or Wide_Get_UTF_16 returns the same sequence of characters as was present in the calls that stored the characters into the buffer, if representable. For a call to Get, if any character in the sequence is not defined in Character, the result is implementation defined. Similarly, for a call to Wide_Get, if any character in the sequence is not defined in Wide_Character, the result is implementation defined. As part of a call on any of the Get functions, the buffer is reset to an empty state, with no stored characters. 34/5

Implementation defined: The value returned by a call to a Text_Buffer Get procedure if any character in the returned sequence is not defined in Character. 34.a/5

Implementation defined: The value returned by a call to a Text_Buffer Wide_Get procedure if any character in the returned sequence is not defined in Wide_Character. 34.b/5

{*AI12-0384-2*} In the case of a Buf of type Text_Buffers.Bounded.Buffer_Type, Text_Truncated (Buf) returns True if the various Put procedures together have attempted to store more than Buf.Max_Characters into Buf. If this function returns True, then the various Get functions return a representation of only the first Buf.Max_Characters characters that were stored in Buf. 35/5

Implementation Advice

{*AI12-0340-1*} Bounded buffer objects should be implemented without dynamic allocation. 36/5

Implementation Advice: Bounded buffer objects should be implemented without dynamic allocation. 36.a.1/5

Extensions to Ada 2012

36.a/5 {*AI12-0340-1*} {*AI12-0384-2*} The packages Strings.Text_Buffers, Strings.Text_Buffers.Unbounded, and Strings.Text_Buffers.Bounded are new.

A.5 The Numerics Packages

1 The library package Numerics is the parent of several child units that provide facilities for mathematical computation. One child, the generic package Generic_Elementary_Functions, is defined in A.5.1, together with nongeneric equivalents; two others, the package Float_Random and the generic package Discrete_Random, are defined in A.5.2. Additional (optional) children are defined in Annex G, "Numerics".

Static Semantics

2/1 *This paragraph was deleted.*

3/5
```
{AI95-00388-01} {AI12-0414-1} package Ada.Numerics
   with Pure is
   Argument_Error : exception;
   Pi : constant :=
          3.14159_26535_89793_23846_26433_83279_50288_41971_69399_37511;
   π  : constant := Pi;
   e  : constant :=
          2.71828_18284_59045_23536_02874_71352_66249_77572_47093_69996;
end Ada.Numerics;
```

4 The Argument_Error exception is raised by a subprogram in a child unit of Numerics to signal that one or more of the actual subprogram parameters are outside the domain of the corresponding mathematical function.

Implementation Permissions

5 The implementation may specify the values of Pi and e to a larger number of significant digits.

5.a **Reason:** 51 digits seem more than adequate for all present computers; converted to binary, the values given above are accurate to more than 160 bits. Nevertheless, the permission allows implementations to accommodate unforeseen hardware advances.

Extensions to Ada 83

5.b Numerics and its children were not predefined in Ada 83.

Extensions to Ada 95

5.c/2 {*AI95-00388-01*} The alternative declaration of π is new.

A.5.1 Elementary Functions

1 Implementation-defined approximations to the mathematical functions known as the "elementary functions" are provided by the subprograms in Numerics.Generic_Elementary_Functions. Nongeneric equivalents of this generic package for each of the predefined floating point types are also provided as children of Numerics.

1.a **Implementation defined:** The accuracy actually achieved by the elementary functions.

Static Semantics

2 The generic library package Numerics.Generic_Elementary_Functions has the following declaration:

```
{AI12-0241-1} generic                                                                    3/5
   type Float_Type is digits <>;

package Ada.Numerics.Generic_Elementary_Functions
   with Pure, Nonblocking is

   function Sqrt    (X           : Float_Type'Base) return Float_Type'Base;             4
   function Log     (X           : Float_Type'Base) return Float_Type'Base;
   function Log     (X, Base     : Float_Type'Base) return Float_Type'Base;
   function Exp     (X           : Float_Type'Base) return Float_Type'Base;
   function "**"    (Left, Right : Float_Type'Base) return Float_Type'Base;

   function Sin     (X           : Float_Type'Base) return Float_Type'Base;             5
   function Sin     (X, Cycle    : Float_Type'Base) return Float_Type'Base;
   function Cos     (X           : Float_Type'Base) return Float_Type'Base;

   function Arccoth (X           : Float_Type'Base) return Float_Type'Base;

end Ada.Numerics.Generic_Elementary_Functions;                                           8
```

{*8652/0020*} {*AI95-00126-01*} The library package Numerics.Elementary_Functions is declared pure and defines the same subprograms as Numerics.Generic_Elementary_Functions, except that the predefined type Float is systematically substituted for Float_Type'Base throughout. Nongeneric equivalents of Numerics.Generic_Elementary_Functions for each of the other predefined floating point types are defined similarly, with the names Numerics.Short_Elementary_Functions, Numerics.Long_Elementary_-Functions, etc. 9/1

Reason: The nongeneric equivalents are provided to allow the programmer to construct simple mathematical applications without being required to understand and use generics. 9.a

The functions have their usual mathematical meanings. When the Base parameter is specified, the Log function computes the logarithm to the given base; otherwise, it computes the natural logarithm. When the Cycle parameter is specified, the parameter X of the forward trigonometric functions (Sin, Cos, Tan, and Cot) and the results of the inverse trigonometric functions (Arcsin, Arccos, Arctan, and Arccot) are measured in units such that a full cycle of revolution has the given value; otherwise, they are measured in radians. 10

11 The computed results of the mathematically multivalued functions are rendered single-valued by the following conventions, which are meant to imply the principal branch:

12 • The results of the Sqrt and Arccosh functions and that of the exponentiation operator are nonnegative.

13 • The result of the Arcsin function is in the quadrant containing the point (1.0, *x*), where *x* is the value of the parameter X. This quadrant is I or IV; thus, the range of the Arcsin function is approximately –π/2.0 to π/2.0 (–Cycle/4.0 to Cycle/4.0, if the parameter Cycle is specified).

14 • The result of the Arccos function is in the quadrant containing the point (*x*, 1.0), where *x* is the value of the parameter X. This quadrant is I or II; thus, the Arccos function ranges from 0.0 to approximately π (Cycle/2.0, if the parameter Cycle is specified).

15 • The results of the Arctan and Arccot functions are in the quadrant containing the point (*x*, *y*), where *x* and *y* are the values of the parameters X and Y, respectively. This may be any quadrant (I through IV) when the parameter X (resp., Y) of Arctan (resp., Arccot) is specified, but it is restricted to quadrants I and IV (resp., I and II) when that parameter is omitted. Thus, the range when that parameter is specified is approximately –π to π (–Cycle/2.0 to Cycle/2.0, if the parameter Cycle is specified); when omitted, the range of Arctan (resp., Arccot) is that of Arcsin (resp., Arccos), as given above. When the point (*x*, *y*) lies on the negative x-axis, the result approximates

16 – π (resp., –π) when the sign of the parameter Y is positive (resp., negative), if Float_Type'Signed_Zeros is True;

17 – π, if Float_Type'Signed_Zeros is False.

18 (In the case of the inverse trigonometric functions, in which a result lying on or near one of the axes may not be exactly representable, the approximation inherent in computing the result may place it in an adjacent quadrant, close to but on the wrong side of the axis.)

Dynamic Semantics

19 The exception Numerics.Argument_Error is raised, signaling a parameter value outside the domain of the corresponding mathematical function, in the following cases:

20 • by any forward or inverse trigonometric function with specified cycle, when the value of the parameter Cycle is zero or negative;

21 • by the Log function with specified base, when the value of the parameter Base is zero, one, or negative;

22 • by the Sqrt and Log functions, when the value of the parameter X is negative;

23 • by the exponentiation operator, when the value of the left operand is negative or when both operands have the value zero;

24 • by the Arcsin, Arccos, and Arctanh functions, when the absolute value of the parameter X exceeds one;

25 • by the Arctan and Arccot functions, when the parameters X and Y both have the value zero;

26 • by the Arccosh function, when the value of the parameter X is less than one; and

27 • by the Arccoth function, when the absolute value of the parameter X is less than one.

28 The exception Constraint_Error is raised, signaling a pole of the mathematical function (analogous to dividing by zero), in the following cases, provided that Float_Type'Machine_Overflows is True:

29 • by the Log, Cot, and Coth functions, when the value of the parameter X is zero;

30 • by the exponentiation operator, when the value of the left operand is zero and the value of the exponent is negative;

- by the Tan function with specified cycle, when the value of the parameter X is an odd multiple of the quarter cycle; 31
- by the Cot function with specified cycle, when the value of the parameter X is zero or a multiple of the half cycle; and 32
- by the Arctanh and Arccoth functions, when the absolute value of the parameter X is one. 33

[Constraint_Error can also be raised when a finite result overflows (see G.2.4); this may occur for parameter values sufficiently *near* poles, and, in the case of some of the functions, for parameter values with sufficiently large magnitudes.] When Float_Type'Machine_Overflows is False, the result at poles is unspecified. 34

Reason: The purpose of raising Constraint_Error (rather than Numerics.Argument_Error) at the poles of a function, when Float_Type'Machine_Overflows is True, is to provide continuous behavior as the actual parameters of the function approach the pole and finally reach it. 34.a

Discussion: It is anticipated that an Ada binding to IEC 559:1989 will be developed in the future. As part of such a binding, the Machine_Overflows attribute of a conformant floating point type will be specified to yield False, which will permit both the predefined arithmetic operations and implementations of the elementary functions to deliver signed infinities (and set the overflow flag defined by the binding) instead of raising Constraint_Error in overflow situations, when traps are disabled. Similarly, it is appropriate for the elementary functions to deliver signed infinities (and set the zero-divide flag defined by the binding) instead of raising Constraint_Error at poles, when traps are disabled. Finally, such a binding should also specify the behavior of the elementary functions, when sensible, given parameters with infinite values. 34.b

{*AI12-0453-1*} When one parameter of a function with multiple parameters represents a pole and another is outside the function's domain, the latter takes precedence and Numerics.Argument_Error is raised. 35/5

Implementation Requirements

In the implementation of Numerics.Generic_Elementary_Functions, the range of intermediate values allowed during the calculation of a final result shall not be affected by any range constraint of the subtype Float_Type. 36

Implementation Note: Implementations of Numerics.Generic_Elementary_Functions written in Ada should therefore avoid declaring local variables of subtype Float_Type; the subtype Float_Type'Base should be used instead. 36.a

In the following cases, evaluation of an elementary function shall yield the *prescribed result*, provided that the preceding rules do not call for an exception to be raised: 37

- When the parameter X has the value zero, the Sqrt, Sin, Arcsin, Tan, Sinh, Arcsinh, Tanh, and Arctanh functions yield a result of zero, and the Exp, Cos, and Cosh functions yield a result of one. 38
- When the parameter X has the value one, the Sqrt function yields a result of one, and the Log, Arccos, and Arccosh functions yield a result of zero. 39
- When the parameter Y has the value zero and the parameter X has a positive value, the Arctan and Arccot functions yield a result of zero. 40
- The results of the Sin, Cos, Tan, and Cot functions with specified cycle are exact when the mathematical result is zero; those of the first two are also exact when the mathematical result is ± 1.0. 41
- Exponentiation by a zero exponent yields the value one. Exponentiation by a unit exponent yields the value of the left operand. Exponentiation of the value one yields the value one. Exponentiation of the value zero yields the value zero. 42

Other accuracy requirements for the elementary functions, which apply only in implementations conforming to the Numerics Annex, and then only in the “strict” mode defined there (see G.2), are given in G.2.4. 43

44 When Float_Type'Signed_Zeros is True, the sign of a zero result shall be as follows:

45 • A prescribed zero result delivered *at the origin* by one of the odd functions (Sin, Arcsin, Sinh, Arcsinh, Tan, Arctan or Arccot as a function of Y when X is fixed and positive, Tanh, and Arctanh) has the sign of the parameter X (Y, in the case of Arctan or Arccot).

46 • A prescribed zero result delivered by one of the odd functions *away from the origin*, or by some other elementary function, has an implementation-defined sign.

46.a **Implementation defined:** The sign of a zero result from some of the operators or functions in Numerics.Generic_Elementary_Functions, when Float_Type'Signed_Zeros is True.

47/5 • {*AI12-0453-1*} [A zero result that is not a prescribed result (that is, one that results from rounding or underflow) has the correct mathematical sign.]

47.a **Reason:** This is a consequence of the rules specified in IEC 559:1989 as they apply to underflow situations with traps disabled.

Implementation Permissions

48/5 {*AI12-0444-1*} The nongeneric equivalent packages can be actual instantiations of the generic package for the appropriate predefined type, though that is not required.

Wording Changes from Ada 83

48.a The semantics of Numerics.Generic_Elementary_Functions differs from Generic_Elementary_Functions as defined in ISO/IEC DIS 11430 (for Ada 83) in the following ways:

48.b • The generic package is a child unit of the package defining the Argument_Error exception.

48.c • DIS 11430 specified names for the nongeneric equivalents, if provided. Here, those nongeneric equivalents are required.

48.d • Implementations are not allowed to impose an optional restriction that the generic actual parameter associated with Float_Type be unconstrained. (In view of the ability to declare variables of subtype Float_Type'Base in implementations of Numerics.Generic_Elementary_Functions, this flexibility is no longer needed.)

48.e • The sign of a prescribed zero result at the origin of the odd functions is specified, when Float_Type'Signed_Zeros is True. This conforms with recommendations of Kahan and other numerical analysts.

48.f • The dependence of Arctan and Arccot on the sign of a parameter value of zero is tied to the value of Float_Type'Signed_Zeros.

48.g • Sqrt is prescribed to yield a result of one when its parameter has the value one. This guarantee makes it easier to achieve certain prescribed results of the complex elementary functions (see G.1.2, “Complex Elementary Functions”).

48.h • Conformance to accuracy requirements is conditional.

Wording Changes from Ada 95

48.i/2 {*8652/0020*} {*AI95-00126-01*} **Corrigendum:** Explicitly stated that the nongeneric equivalents of Generic_Elementary_Functions are pure.

A.5.2 Random Number Generation

1 [Facilities for the generation of pseudo-random floating point numbers are provided in the package Numerics.Float_Random; the generic package Numerics.Discrete_Random provides similar facilities for the generation of pseudo-random integers and pseudo-random values of enumeration types. For brevity, pseudo-random values of any of these types are called *random numbers*.

2 Some of the facilities provided are basic to all applications of random numbers. These include a limited private type each of whose objects serves as the generator of a (possibly distinct) sequence of random numbers; a function to obtain the “next” random number from a given sequence of random numbers (that

is, from its generator); and subprograms to initialize or reinitialize a given generator to a time-dependent state or a state denoted by a single integer.

Other facilities are provided specifically for advanced applications. These include subprograms to save and restore the state of a given generator; a private type whose objects can be used to hold the saved state of a generator; and subprograms to obtain a string representation of a given generator state, or, given such a string representation, the corresponding state.] 3

Discussion: These facilities support a variety of requirements ranging from repeatable sequences (for debugging) to unique sequences in each execution of a program. 3.a

Static Semantics

The library package Numerics.Float_Random has the following declaration: 4

```
{AI12-0302-1} package Ada.Numerics.Float_Random                                    5/5
   with Global => in out synchronized is

   -- Basic facilities                                                            6

   type Generator is limited private;                                            7

{AI12-0302-1}    subtype Uniformly_Distributed is Float range 0.0 .. 1.0;        8/5
   function Random (Gen : Generator) return Uniformly_Distributed
      with Global => overriding in out Gen;

{AI12-0302-1}    procedure Reset (Gen       : in Generator;                      9/5
                                  Initiator : in Integer)
      with Global => overriding in out Gen;
   procedure Reset (Gen       : in Generator)
      with Global => overriding in out Gen;

   -- Advanced facilities                                                        10

   type State is private;                                                        11

{AI12-0302-1}    procedure Save  (Gen        : in  Generator;                   12/5
                                  To_State   : out State);
   procedure Reset (Gen        : in  Generator;
                    From_State : in  State)
      with Global => overriding in out Gen;

   Max_Image_Width : constant := implementation-defined integer value;           13

   function Image (Of_State    : State)  return String;                          14
   function Value (Coded_State : String) return State;

private                                                                          15
   ... -- not specified by the language
end Ada.Numerics.Float_Random;
```

{*AI95-00360-01*} The type Generator needs finalization (see 7.6). 15.1/2

The generic library package Numerics.Discrete_Random has the following declaration: 16

```
{AI12-0302-1} generic                                                            17/5
   type Result_Subtype is (<>);
package Ada.Numerics.Discrete_Random
   with Global => in out synchronized is

   -- Basic facilities                                                           18

   type Generator is limited private;                                            19

{AI12-0302-1}    function Random (Gen : Generator) return Result_Subtype        20/5
      with Global => overriding in out Gen;

{AI12-0144-1} {AI12-0302-1}    function Random (Gen   : Generator;               20.1/5
                               First : Result_Subtype;
                               Last  : Result_Subtype) return Result_Subtype
      with Post => Random'Result in First .. Last,
           Global => overriding in out Gen;
```

21/5 {*AI12-0302-1*}
```
   procedure Reset (Gen       : in Generator;
                    Initiator : in Integer)
      with Global => overriding in out Gen;
   procedure Reset (Gen       : in Generator)
      with Global => overriding in out Gen;
```

22
```
   -- Advanced facilities
```

23
```
   type State is private;
```

24/5 {*AI12-0302-1*}
```
   procedure Save  (Gen        : in  Generator;
                    To_State   : out State);
   procedure Reset (Gen        : in  Generator;
                    From_State : in  State)
      with Global => overriding in out Gen;
```

25
```
   Max_Image_Width : constant := implementation-defined integer value;
```

26
```
   function Image (Of_State    : State)  return String;
   function Value (Coded_State : String) return State;
```

27
```
private
   ... -- not specified by the language
end Ada.Numerics.Discrete_Random;
```

27.a **Implementation defined:** The value of Numerics.Float_Random.Max_Image_Width.

27.b **Implementation defined:** The value of Numerics.Discrete_Random.Max_Image_Width.

27.c/1 **Implementation Note:** {*8652/0097*} {*AI95-00115-01*} The following is a possible implementation of the private part of Numerics.Float_Random (assuming the presence of "**with** Ada.Finalization;" as a context clause):

27.d
```
type State is ...;
type Access_State is access State;
type Generator is new Finalization.Limited_Controlled with
   record
      S : Access_State := new State'(...);
   end record;
procedure Finalize (G : in out Generator);
```

27.d.1/2 {*8652/0097*} {*AI95-00115-01*} {*AI95-00344-01*} Numerics.Discrete_Random.Generator also can be implemented this way.

27.e Clearly some level of indirection is required in the implementation of a Generator, since the parameter mode is **in** for all operations on a Generator. For this reason, Numerics.Float_Random and Numerics.Discrete_Random cannot be declared pure.

27.1/2 {*AI95-00360-01*} The type Generator needs finalization (see 7.6) in every instantiation of Numerics.Discrete_Random.

28 An object of the limited private type Generator is associated with a sequence of random numbers. Each generator has a hidden (internal) state, which the operations on generators use to determine the position in the associated sequence. All generators are implicitly initialized to an unspecified state that does not vary from one program execution to another; they may also be explicitly initialized, or reinitialized, to a time-dependent state, to a previously saved state, or to a state uniquely denoted by an integer value.

28.a **Discussion:** The repeatability provided by the implicit initialization may be exploited for testing or debugging purposes.

29/5 {*AI05-0280-1*} {*AI12-0445-1*} An object of the private type State can be used to hold the internal state of a generator. Such objects are only necessary if the application is designed to save and restore generator states or to examine or manufacture them. The implicit initial value of type State corresponds to the implicit initial value of all generators.

29.a/3 **Discussion:** {*AI05-0280-1*} All generators are implicitly initialized to the same unchanging value, and using Reset on a default initialized object of type State will produce a generator with that same value.

30 The operations on generators affect the state and therefore the future values of the associated sequence. The semantics of the operations on generators and states are defined below.

31
```
function Random (Gen : Generator) return Uniformly_Distributed;
function Random (Gen : Generator) return Result_Subtype;
```

{*AI12-0144-1*} Obtains the "next" random number from the given generator, relative to its current state, according to an implementation-defined algorithm. 32/5

This paragraph was deleted. 32.a/2

Discussion: The algorithm is the subject of a Documentation Requirement, so we don't separately summarize this implementation-defined item. 32.a.1/2

Reason: The requirement for a level of indirection in accessing the internal state of a generator arises from the desire to make Random a function, rather than a procedure. 32.b

```
{AI12-0144-1} function Random (Gen   : Generator;                                    32.1/5
                               First : Result_Subtype;
                               Last  : Result_Subtype) return Result_Subtype
   with Post => Random'Result in First .. Last;
```

{*AI12-0144-1*} Obtains the "next" random number from the given generator, relative to its current state, according to an implementation-defined algorithm. If the range First .. Last is a null range, Constraint_Error is raised. 32.2/5

```
procedure Reset (Gen       : in Generator;                                           33
                 Initiator : in Integer);
procedure Reset (Gen       : in Generator);
```

Sets the state of the specified generator to one that is an unspecified function of the value of the parameter Initiator (or to a time-dependent state, if only a generator parameter is specified). The latter form of the procedure is known as the *time-dependent Reset procedure*. 34

Implementation Note: The time-dependent Reset procedure can be implemented by mapping the current time and date as determined by the system clock into a state, but other implementations are possible. For example, a white-noise generator or a radioactive source can be used to generate time-dependent states. 34.a

```
procedure Save  (Gen        : in  Generator;                                         35
                 To_State   : out State);
procedure Reset (Gen        : in  Generator;
                 From_State : in  State);
```

Save obtains the current state of a generator. Reset gives a generator the specified state. A generator that is reset to a state previously obtained by invoking Save is restored to the state it had when Save was invoked. 36

```
function Image (Of_State    : State)  return String;                                 37
function Value (Coded_State : String) return State;
```

Image provides a representation of a state coded (in an implementation-defined way) as a string whose length is bounded by the value of Max_Image_Width. Value is the inverse of Image: Value(Image(S)) = S for each state S that can be obtained from a generator by invoking Save. 38

Implementation defined: The string representation of a random number generator's state. 38.a

Dynamic Semantics

Instantiation of Numerics.Discrete_Random with a subtype having a null range raises Constraint_Error. 39

This paragraph was deleted.{*8652/0050*} {*AI95-00089*} 40/1

Bounded (Run-Time) Errors

{*8652/0050*} {*AI95-00089*} {*AI12-0445-1*} It is a bounded error to invoke Value with a string that is not the image of any generator state. If the error is detected, Constraint_Error or Program_Error is raised. Otherwise, a call to Reset with the resulting state will produce a generator such that calls to Random with this generator will produce a sequence of values of the appropriate subtype, but which are not necessarily random in character. That is, the sequence of values do not necessarily fulfill the implementation requirements of this subclause. 40.1/5

Implementation Requirements

40.2/5 {*AI12-0144-1*} Each call of a Random function has a *result range*; this is the range First .. Last for the version of Random with First and Last parameters and the range of the result subtype of the function otherwise.

41/5 {*AI12-0144-1*} A sufficiently long sequence of random numbers obtained by consecutive calls to Random that have the same generator and result range is approximately uniformly distributed over the result range.

41.a/5 **Discussion:** {*AI12-0005-1*} {*AI12-0144-1*} In this rule, "consecutive" means at least that there are no intervening explicit calls involving the same generator. This restricts the rule to only applying to cases where just the Random function changes the generator. We don't mean to impose a requirement if there are intervening calls to Reset, to Random with the same generator but a different result range, or any other case that would affect the sequence of values returned. Operations that use the resulting random values (for instance, to store them somewhere) are not considered in determining if calls are consecutive.

42/5 {*AI12-0144-1*} A Random function in an instantiation of Numerics.Discrete_Random is guaranteed to yield each value in its result range in a finite number of calls, provided that the number of such values does not exceed 2^{15}.

43 Other performance requirements for the random number generator, which apply only in implementations conforming to the Numerics Annex, and then only in the "strict" mode defined there (see G.2), are given in G.2.5.

Documentation Requirements

44 No one algorithm for random number generation is best for all applications. To enable the user to determine the suitability of the random number generators for the intended application, the implementation shall describe the algorithm used and shall give its period, if known exactly, or a lower bound on the period, if the exact period is unknown. Periods that are so long that the periodicity is unobservable in practice can be described in such terms, without giving a numerical bound.

44.a/2 **Documentation Requirement:** The algorithm used for random number generation, including a description of its period.

45 The implementation also shall document the minimum time interval between calls to the time-dependent Reset procedure that are guaranteed to initiate different sequences, and it shall document the nature of the strings that Value will accept without raising Constraint_Error.

45.a/2 *This paragraph was deleted.*

45.b/2 **Documentation Requirement:** The minimum time interval between calls to the time-dependent Reset procedure that is guaranteed to initiate different random number sequences.

Implementation Advice

46 Any storage associated with an object of type Generator should be reclaimed on exit from the scope of the object.

46.a.1/2 **Implementation Advice:** Any storage associated with an object of type Generator of the random number packages should be reclaimed on exit from the scope of the object.

46.a **Ramification:** A level of indirection is implicit in the semantics of the operations, given that they all take parameters of mode **in**. This implies that the full type of Generator probably should be a controlled type, with appropriate finalization to reclaim any heap-allocated storage.

47 If the generator period is sufficiently long in relation to the number of distinct initiator values, then each possible value of Initiator passed to Reset should initiate a sequence of random numbers that does not, in a practical sense, overlap the sequence initiated by any other value. If this is not possible, then the mapping between initiator values and generator states should be a rapidly varying function of the initiator value.

Implementation Advice: Each value of Initiator passed to Reset for the random number packages should initiate a distinct sequence of random numbers, or, if that is not possible, be at least a rapidly varying function of the initiator value. 47.a/2

NOTE 1 If two or more tasks are to share the same generator, then the tasks have to synchronize their access to the generator as for any shared variable (see 9.10). 48

NOTE 2 Within a given implementation, a repeatable random number sequence can be obtained by relying on the implicit initialization of generators or by explicitly initializing a generator with a repeatable initiator value. Different sequences of random numbers can be obtained from a given generator in different program executions by explicitly initializing the generator to a time-dependent state. 49

NOTE 3 {*AI12-0442-1*} {*AI12-0447-1*} A given implementation of the Random function in Numerics.Float_Random is not guaranteed to be capable of delivering the values 0.0 or 1.0. Applications will be more portable if they assume that these values, or values sufficiently close to them to behave indistinguishably from them, can occur. If a sequence of random integers from some range is necessary, the application should use one of the Random functions in an appropriate instantiation of Numerics.Discrete_Random, rather than transforming the result of the Random function in Numerics.Float_Random. 50/5

This paragraph was deleted.{*AI12-0442-1*} 51/5

Reason: {*AI12-0442-1*} One might think that a simple transformation of the result of the floating point Random function such as `Integer(Float(M) * Random(G)) mod M` would give a uniform distribution. But this is only true if the period of the underlying generator is a multiple of `M`. (This usually requires that `M` be a power of two.) In other cases, the **mod** operation maps slightly more random values to some result values than others. It is easy to see this: consider a 4-bit random integer (with a range of 0 .. 15). If one **mod**s this by 6 to get a value in 0 .. 5 (to which one would add 1 to get the value of a die roll), 3 values would be mapped to each value 0 .. 3, but only 2 values would be mapped to 4 and 5. Even when the input is uniformly distributed, the output clearly is not. A similar effect occurs regardless of the number of bits in the random integer. Since it takes care to get this right, users should use the provided functions (which presumably do this correctly – AI12-0144-1 contains a correct algorithm) and resist the urge to "roll-their-own". 51.a/5

NOTE 4 {*AI12-0442-1*} Exponentially distributed (floating point) random numbers with mean and standard deviation 1.0 can be obtained by the transformation 52/5

{*AI95-00434-01*} `-Log(Random(G) + Float'Model_Small)` 53/2

where Log comes from Numerics.Elementary_Functions (see A.5.1); in this expression, the addition of Float'Model_Small avoids the exception that would be raised were Log to be given the value zero, without affecting the result (in most implementations) when Random returns a nonzero value. 54

Examples

Example of a program that plays a simulated dice game: 55

```
with Ada.Numerics.Discrete_Random;                                    56
procedure Dice_Game is
   subtype Die is Integer range 1 .. 6;
   subtype Dice is Integer range 2*Die'First .. 2*Die'Last;
   package Random_Die is new Ada.Numerics.Discrete_Random (Die);
   use Random_Die;
   G : Generator;
   D : Dice;
begin
   Reset (G);  -- Start the generator in a unique state in each run
   loop
      -- Roll a pair of dice; sum and process the results
      D := Random(G) + Random(G);
      ...
   end loop;
end Dice_Game;
```

57 *Example of a program that simulates coin tosses:*

58
```
with Ada.Numerics.Discrete_Random;
procedure Flip_A_Coin is
   type Coin is (Heads, Tails);
   package Random_Coin is new Ada.Numerics.Discrete_Random (Coin);
   use Random_Coin;
   G : Generator;
begin
   Reset (G);  -- Start the generator in a unique state in each run
   loop
      -- Toss a coin and process the result
      case Random(G) is
          when Heads =>
             ...
          when Tails =>
             ...
      end case;
   ...
   end loop;
end Flip_A_Coin;
```

59 *Example of a parallel simulation of a physical system, with a separate generator of event probabilities in each task:*

60
```
with Ada.Numerics.Float_Random;
procedure Parallel_Simulation is
   use Ada.Numerics.Float_Random;
   task type Worker is
      entry Initialize_Generator (Initiator : in Integer);
      ...
   end Worker;
   W : array (1 .. 10) of Worker;
   task body Worker is
      G : Generator;
      Probability_Of_Event : Uniformly_Distributed;
   begin
      accept Initialize_Generator (Initiator : in Integer) do
         Reset (G, Initiator);
      end Initialize_Generator;
      loop
         ...
         Probability_Of_Event := Random(G);
         ...
      end loop;
   end Worker;
begin
   -- Initialize the generators in the Worker tasks to different states
   for I in W'Range loop
      W(I).Initialize_Generator (I);
   end loop;
   ... -- Wait for the Worker tasks to terminate
end Parallel_Simulation;
```

61/5 {*AI12-0452-1*} Although each Worker task initializes its generator to a different state, those states will be the same in every execution of the program. The generator states can be initialized uniquely in each program execution by instantiating Ada.Numerics.Discrete_Random for the type Integer in the main procedure, resetting the generator obtained from that instance to a time-dependent state, and then using random integers obtained from that generator to initialize the generators in each Worker task.

Incompatibilities With Ada 95

62.a/2 {*AI95-00360-01*} **Amendment Correction:** Type Generator in Numerics.Float_Random and in an instance of Numerics.Discrete_Random is defined to need finalization. If the restriction No_Nested_Finalization (see D.7) applies to the partition, and Generator does not have a controlled part, it will not be allowed in local objects in Ada 2005

whereas it would be allowed in original Ada 95. Such code is not portable, as another Ada compiler may have a controlled part in Generator, and thus would be illegal.

Wording Changes from Ada 95

{*8652/0050*} {*AI95-00089-01*} {*AI05-0005-1*} **Corrigendum:** Made the passing of an incorrect Image of a generator a bounded error, as it might not be practical to check for problems (if a generator consists of several related values). 62.b/3

Wording Changes from Ada 2005

{*AI05-0280-1*} **Correction:** Specified the implicit initial value for (sub)type State. This was unspecified in Ada 95 and Ada 2005, so a program depending on some other initial value is very unlikely and certainly was not portable. An implementation can use default expressions, aspect Default_Value, or aspect Default_Component_Value to keep the representation of the type unchanged while meeting this new requirement. 62.c/3

Extensions to Ada 2012

{*AI12-0144-1*} The function Random with First and Last parameters is new. 62.d/5

A.5.3 Attributes of Floating Point Types

Static Semantics

The following *representation-oriented attributes* are defined for every subtype S of a floating point type *T*. 1

S'Machine_Radix 2

Yields the radix of the hardware representation of the type *T*. The value of this attribute is of the type *universal_integer*.

The values of other representation-oriented attributes of a floating point subtype, and of the "primitive function" attributes of a floating point subtype described later, are defined in terms of a particular representation of nonzero values called the *canonical form*. The canonical form (for the type *T*) is the form 3

$$\pm\, mantissa \cdot T\text{'Machine\_Radix}^{exponent}$$

where

- *mantissa* is a fraction in the number base *T*'Machine_Radix, the first digit of which is nonzero, and 4
- *exponent* is an integer. 5

S'Machine_Mantissa 6

Yields the largest value of *p* such that every value expressible in the canonical form (for the type *T*), having a *p*-digit *mantissa* and an *exponent* between *T*'Machine_Emin and *T*'Machine_Emax, is a machine number (see 3.5.7) of the type *T*. This attribute yields a value of the type *universal_integer*.

Ramification: Values of a type held in an extended register are, in general, not machine numbers of the type, since they cannot be expressed in the canonical form with a sufficiently short *mantissa*. 6.a

S'Machine_Emin 7

Yields the smallest (most negative) value of *exponent* such that every value expressible in the canonical form (for the type *T*), having a *mantissa* of *T*'Machine_Mantissa digits, is a machine number (see 3.5.7) of the type *T*. This attribute yields a value of the type *universal_integer*.

S'Machine_Emax 8

Yields the largest (most positive) value of *exponent* such that every value expressible in the canonical form (for the type *T*), having a *mantissa* of *T*'Machine_Mantissa digits, is a machine number (see 3.5.7) of the type *T*. This attribute yields a value of the type *universal_integer*.

8.a **Ramification:** Note that the above definitions do not determine unique values for the representation-oriented attributes of floating point types. The implementation may choose any set of values that collectively satisfies the definitions.

9 S'Denorm Yields the value True if every value expressible in the form

$$\pm \textit{mantissa} \cdot \textit{T}\text{'Machine\_Radix}^{\textit{T}\text{'Machine\_Emin}}$$

where *mantissa* is a nonzero *T*'Machine_Mantissa-digit fraction in the number base *T*'Machine_Radix, the first digit of which is zero, is a machine number (see 3.5.7) of the type *T*; yields the value False otherwise. The value of this attribute is of the predefined type Boolean.

10 The values described by the formula in the definition of S'Denorm are called *denormalized numbers*. A nonzero machine number that is not a denormalized number is a *normalized number*. A normalized number *x* of a given type *T* is said to be *represented in canonical form* when it is expressed in the canonical form (for the type *T*) with a *mantissa* having *T*'Machine_Mantissa digits; the resulting form is the *canonical-form representation* of *x*.

10.a **Discussion:** The intent is that S'Denorm be True when such denormalized numbers exist and are generated in the circumstances defined by IEC 559:1989, though the latter requirement is not formalized here.

11 S'Machine_Rounds
Yields the value True if rounding is performed on inexact results of every predefined operation that yields a result of the type *T*; yields the value False otherwise. The value of this attribute is of the predefined type Boolean.

11.a **Discussion:** It is difficult to be more precise about what it means to round the result of a predefined operation. If the implementation does not use extended registers, so that every arithmetic result is necessarily a machine number, then rounding seems to imply two things:

11.b - S'Model_Mantissa = S'Machine_Mantissa, so that operand preperturbation never occurs;

11.c - when the exact mathematical result is not a machine number, the result of a predefined operation must be the nearer of the two adjacent machine numbers.

11.d Technically, this attribute should yield False when extended registers are used, since a few computed results will cross over the half-way point as a result of double rounding, if and when a value held in an extended register has to be reduced in precision to that of the machine numbers. It does not seem desirable to preclude the use of extended registers when S'Machine_Rounds could otherwise be True.

12 S'Machine_Overflows
Yields the value True if overflow and divide-by-zero are detected and reported by raising Constraint_Error for every predefined operation that yields a result of the type *T*; yields the value False otherwise. The value of this attribute is of the predefined type Boolean.

13 S'Signed_Zeros
Yields the value True if the hardware representation for the type *T* has the capability of representing both positively and negatively signed zeros, these being generated and used by the predefined operations of the type *T* as specified in IEC 559:1989; yields the value False otherwise. The value of this attribute is of the predefined type Boolean.

14 For every value *x* of a floating point type *T*, the *normalized exponent* of *x* is defined as follows:

15 - the normalized exponent of zero is (by convention) zero;

16 - for nonzero *x*, the normalized exponent of *x* is the unique integer *k* such that $\textit{T}\text{'Machine\_Radix}^{k-1} \le |x| < \textit{T}\text{'Machine\_Radix}^{k}$.

16.a **Ramification:** The normalized exponent of a normalized number *x* is the value of *exponent* in the canonical-form representation of *x*.

16.b The normalized exponent of a denormalized number is less than the value of *T*'Machine_Emin.

17 The following *primitive function attributes* are defined for any subtype S of a floating point type *T*.

18 S'Exponent S'Exponent denotes a function with the following specification:

19
```
function S'Exponent (X : T)
  return universal_integer
```

The function yields the normalized exponent of *X*. 20

S'Fraction S'Fraction denotes a function with the following specification: 21

```
function S'Fraction (X : T)
  return T
```
22

The function yields the value $X \cdot T\text{'Machine\_Radix}^{-k}$, where *k* is the normalized exponent of *X*. A zero result[, which can only occur when *X* is zero,] has the sign of *X*. 23

Discussion: Informally, when *X* is a normalized number, the result is the value obtained by replacing the *exponent* by zero in the canonical-form representation of *X*. 23.a

Ramification: Except when *X* is zero, the magnitude of the result is greater than or equal to the reciprocal of *T*'Machine_Radix and less than one; consequently, the result is always a normalized number, even when *X* is a denormalized number. 23.b

Implementation Note: When *X* is a denormalized number, the result is the value obtained by replacing the *exponent* by zero in the canonical-form representation of the result of scaling *X* up sufficiently to normalize it. 23.c

S'Compose S'Compose denotes a function with the following specification: 24

```
function S'Compose (Fraction : T;
                    Exponent : universal_integer)
  return T
```
25

Let *v* be the value $Fraction \cdot T\text{'Machine\_Radix}^{Exponent-k}$, where *k* is the normalized exponent of *Fraction*. If *v* is a machine number of the type *T*, or if $|v| \geq T\text{'Model\_Small}$, the function yields *v*; otherwise, it yields either one of the machine numbers of the type *T* adjacent to *v*. Constraint_Error is optionally raised if *v* is outside the base range of S. A zero result has the sign of *Fraction* when S'Signed_Zeros is True. 26

Discussion: Informally, when *Fraction* and *v* are both normalized numbers, the result is the value obtained by replacing the *exponent* by *Exponent* in the canonical-form representation of *Fraction*. 26.a

Ramification: If *Exponent* is less than *T*'Machine_Emin and *Fraction* is nonzero, the result is either zero, *T*'Model_Small, or (if *T*'Denorm is True) a denormalized number. 26.b

S'Scaling S'Scaling denotes a function with the following specification: 27

```
function S'Scaling (X : T;
                    Adjustment : universal_integer)
  return T
```
28

Let *v* be the value $X \cdot T\text{'Machine\_Radix}^{Adjustment}$. If *v* is a machine number of the type *T*, or if $|v| \geq T\text{'Model\_Small}$, the function yields *v*; otherwise, it yields either one of the machine numbers of the type *T* adjacent to *v*. Constraint_Error is optionally raised if *v* is outside the base range of S. A zero result has the sign of *X* when S'Signed_Zeros is True. 29

Discussion: Informally, when *X* and *v* are both normalized numbers, the result is the value obtained by increasing the *exponent* by *Adjustment* in the canonical-form representation of *X*. 29.a

Ramification: {*AI12-0453-1*} If *Adjustment* is sufficiently small (that is, sufficiently negative), the result is either zero, *T*'Model_Small, or (if *T*'Denorm is True) a denormalized number. 29.b/5

S'Floor S'Floor denotes a function with the following specification: 30

```
function S'Floor (X : T)
  return T
```
31

{*AI12-0453-1*} The function yields the value $\lfloor X \rfloor$, that is, the largest (most positive) integral value less than or equal to *X*. When *X* is zero, the result has the sign of *X*; a zero result otherwise has a positive sign. 32/5

S'Ceiling S'Ceiling denotes a function with the following specification: 33

```
function S'Ceiling (X : T)
  return T
```
34

{*AI12-0453-1*} The function yields the value $\lceil X \rceil$, that is, the smallest (most negative) integral value greater than or equal to *X*. When *X* is zero, the result has the sign of *X*; a zero result otherwise has a negative sign when S'Signed_Zeros is True. 35/5

36 S'Rounding S'Rounding denotes a function with the following specification:

37
```
function S'Rounding (X : T)
  return T
```

38 The function yields the integral value nearest to *X*, rounding away from zero if *X* lies exactly halfway between two integers. A zero result has the sign of *X* when S'Signed_Zeros is True.

39 S'Unbiased_Rounding
S'Unbiased_Rounding denotes a function with the following specification:

40
```
function S'Unbiased_Rounding (X : T)
  return T
```

41 The function yields the integral value nearest to *X*, rounding toward the even integer if *X* lies exactly halfway between two integers. A zero result has the sign of *X* when S'Signed_Zeros is True.

41.1/2 S'Machine_Rounding
{*AI95-00267-01*} S'Machine_Rounding denotes a function with the following specification:

41.2/2
```
function S'Machine_Rounding (X : T)
  return T
```

41.3/2 The function yields the integral value nearest to *X*. If *X* lies exactly halfway between two integers, one of those integers is returned, but which of them is returned is unspecified. A zero result has the sign of *X* when S'Signed_Zeros is True. This function provides access to the rounding behavior which is most efficient on the target processor.

41.a.1/2 **Discussion:** We leave the rounding unspecified, so that users cannot depend on a particular rounding. This attribute is intended for use in cases where the particular rounding chosen is irrelevant. If there is a need to know which way values halfway between two integers are rounded, one of the other rounding attributes should be used.

42 S'Truncation
S'Truncation denotes a function with the following specification:

43
```
function S'Truncation (X : T)
  return T
```

44 The function yields the value $\lceil X \rceil$ when *X* is negative, and $\lfloor X \rfloor$ otherwise. A zero result has the sign of *X* when S'Signed_Zeros is True.

45 S'Remainder
S'Remainder denotes a function with the following specification:

46
```
function S'Remainder (X, Y : T)
  return T
```

47 For nonzero *Y*, let *v* be the value $X - n \cdot Y$, where *n* is the integer nearest to the exact value of *X*/*Y*; if $|n - X/Y| = 1/2$, then *n* is chosen to be even. If *v* is a machine number of the type *T*, the function yields *v*; otherwise, it yields zero. Constraint_Error is raised if *Y* is zero. A zero result has the sign of *X* when S'Signed_Zeros is True.

47.a **Ramification:** The magnitude of the result is less than or equal to one-half the magnitude of *Y*.

47.b **Discussion:** Given machine numbers *X* and *Y* of the type *T*, *v* is necessarily a machine number of the type *T*, except when *Y* is in the neighborhood of zero, *X* is sufficiently close to a multiple of *Y*, and *T*'Denorm is False.

48 S'Adjacent S'Adjacent denotes a function with the following specification:

49
```
function S'Adjacent (X, Towards : T)
  return T
```

50 If *Towards* = *X*, the function yields *X*; otherwise, it yields the machine number of the type *T* adjacent to *X* in the direction of *Towards*, if that machine number exists. If the result would be outside the base range of S, Constraint_Error is raised. When *T*'Signed_Zeros is True, a zero result has the sign of *X*. When *Towards* is zero, its sign has no bearing on the result.

50.a **Ramification:** The value of S'Adjacent(0.0, 1.0) is the smallest normalized positive number of the type *T* when *T*'Denorm is False and the smallest denormalized positive number of the type *T* when *T*'Denorm is True.

S'Copy_Sign 51

S'Copy_Sign denotes a function with the following specification:

```
function S'Copy_Sign (Value, Sign : T)
  return T
```
52

If the value of *Value* is nonzero, the function yields a result whose magnitude is that of *Value* and whose sign is that of *Sign*; otherwise, it yields the value zero. Constraint_Error is optionally raised if the result is outside the base range of S. A zero result has the sign of *Sign* when S'Signed_Zeros is True. 53

Discussion: S'Copy_Sign is provided for convenience in restoring the sign to a quantity from which it has been temporarily removed, or to a related quantity. When S'Signed_Zeros is True, it is also instrumental in determining the sign of a zero quantity, when required. (Because negative and positive zeros compare equal in systems conforming to IEC 559:1989, a negative zero does *not* appear to be negative when compared to zero.) The sign determination is accomplished by transferring the sign of the zero quantity to a nonzero quantity and then testing for a negative result. 53.a

S'Leading_Part 54

S'Leading_Part denotes a function with the following specification:

```
function S'Leading_Part (X : T;
                         Radix_Digits : universal_integer)
  return T
```
55

Let v be the value T'Machine_Radix$^{k-Radix_Digits}$, where k is the normalized exponent of X. The function yields the value 56

- $\lfloor X/v \rfloor \cdot v$, when X is nonnegative and *Radix_Digits* is positive; 57
- $\lceil X/v \rceil \cdot v$, when X is negative and *Radix_Digits* is positive. 58

Constraint_Error is raised when *Radix_Digits* is zero or negative. A zero result[, which can only occur when X is zero,] has the sign of X. 59

Discussion: Informally, if X is nonzero, the result is the value obtained by retaining only the specified number of (leading) significant digits of X (in the machine radix), setting all other digits to zero. 59.a

Implementation Note: The result can be obtained by first scaling X up, if necessary to normalize it, then masking the mantissa so as to retain only the specified number of leading digits, then scaling the result back down if X was scaled up. 59.b

S'Machine S'Machine denotes a function with the following specification: 60

```
function S'Machine (X : T)
  return T
```
61

If X is a machine number of the type T, the function yields X; otherwise, it yields the value obtained by rounding or truncating X to either one of the adjacent machine numbers of the type T. Constraint_Error is raised if rounding or truncating X to the precision of the machine numbers results in a value outside the base range of S. A zero result has the sign of X when S'Signed_Zeros is True. 62

Discussion: {*AI05-0005-1*} All of the primitive function attributes except Rounding and Machine correspond to subprograms in the Generic_Primitive_Functions generic package that was proposed as a separate ISO standard (ISO/IEC DIS 11729) for Ada 83. The Scaling, Unbiased_Rounding, and Truncation attributes correspond to the Scale, Round, and Truncate functions, respectively, in Generic_Primitive_Functions. The Rounding attribute rounds away from zero; this functionality was not provided in Generic_Primitive_Functions. The name Round was not available for either of the primitive function attributes that perform rounding, since an attribute of that name is used for a different purpose for decimal fixed point types. Likewise, the name Scale was not available, since an attribute of that name is also used for a different purpose for decimal fixed point types. The functionality of the Machine attribute was also not provided in Generic_Primitive_Functions. The functionality of the Decompose procedure of Generic_Primitive_Functions is only provided in the form of the separate attributes Exponent and Fraction. The functionality of the Successor and Predecessor functions of Generic_Primitive_Functions is provided by the extension of the existing Succ and Pred attributes. 62.a/3

Implementation Note: The primitive function attributes may be implemented either with appropriate floating point arithmetic operations or with integer and logical operations that act on parts of the representation directly. The latter is strongly encouraged when it is more efficient than the former; it is mandatory when the former cannot deliver the required accuracy due to limitations of the implementation's arithmetic operations. 62.b

63 The following *model-oriented attributes* are defined for any subtype S of a floating point type *T*.

64 S'Model_Mantissa

If the Numerics Annex is not supported, this attribute yields an implementation defined value that is greater than or equal to $\lceil d \cdot \log(10) / \log(T\text{'Machine\_Radix}) \rceil + 1$, where *d* is the requested decimal precision of *T*, and less than or equal to the value of *T*'Machine_Mantissa. See G.2.2 for further requirements that apply to implementations supporting the Numerics Annex. The value of this attribute is of the type *universal_integer*.

65 S'Model_Emin

If the Numerics Annex is not supported, this attribute yields an implementation defined value that is greater than or equal to the value of *T*'Machine_Emin. See G.2.2 for further requirements that apply to implementations supporting the Numerics Annex. The value of this attribute is of the type *universal_integer*.

66 S'Model_Epsilon

Yields the value $T\text{'Machine\_Radix}^{1 - T\text{'Model\_Mantissa}}$. The value of this attribute is of the type *universal_real*.

66.a **Discussion:** In most implementations, this attribute yields the absolute value of the difference between one and the smallest machine number of the type *T* above one which, when added to one, yields a machine number different from one. Further discussion can be found in G.2.2.

67 S'Model_Small

Yields the value $T\text{'Machine\_Radix}^{T\text{'Model\_Emin} - 1}$. The value of this attribute is of the type *universal_real*.

67.a/5 **Discussion:** {*AI12-0453-1*} In most implementations, this attribute yields the smallest positive normalized number of the type *T*, that is, the number corresponding to the positive underflow threshold. In some implementations employing a radix-complement representation for the type *T*, the positive underflow threshold is closer to zero than is the negative underflow threshold, with the consequence that the smallest positive normalized number does not coincide with the positive underflow threshold that is, it exceeds the latter). Further discussion can be found in G.2.2.

68 S'Model S'Model denotes a function with the following specification:

69
```
function S'Model (X : T)
  return T
```

70 If the Numerics Annex is not supported, the meaning of this attribute is implementation defined; see G.2.2 for the definition that applies to implementations supporting the Numerics Annex.

71 S'Safe_First

Yields the lower bound of the safe range (see 3.5.7) of the type *T*. If the Numerics Annex is not supported, the value of this attribute is implementation defined; see G.2.2 for the definition that applies to implementations supporting the Numerics Annex. The value of this attribute is of the type *universal_real*.

72 S'Safe_Last

Yields the upper bound of the safe range (see 3.5.7) of the type *T*. If the Numerics Annex is not supported, the value of this attribute is implementation defined; see G.2.2 for the definition that applies to implementations supporting the Numerics Annex. The value of this attribute is of the type *universal_real*.

72.a **Discussion:** A predefined floating point arithmetic operation that yields a value in the safe range of its result type is guaranteed not to overflow.

72.b **To be honest:** An exception is made for exponentiation by a negative exponent in 4.5.6.

72.c **Implementation defined:** The values of the Model_Mantissa, Model_Emin, Model_Epsilon, Model, Safe_First, and Safe_Last attributes, if the Numerics Annex is not supported.

Incompatibilities With Ada 83

The Epsilon and Mantissa attributes of floating point types are removed from the language and replaced by Model_Epsilon and Model_Mantissa, which may have different values (as a result of changes in the definition of model numbers); the replacement of one set of attributes by another is intended to convert what would be an inconsistent change into an incompatible change. 72.d

The Emax, Small, Large, Safe_Emax, Safe_Small, and Safe_Large attributes of floating point types are removed from the language. Small and Safe_Small are collectively replaced by Model_Small, which is functionally equivalent to Safe_Small, though it may have a slightly different value. The others are collectively replaced by Safe_First and Safe_Last. Safe_Last is functionally equivalent to Safe_Large, though it may have a different value; Safe_First is comparable to the negation of Safe_Large but may differ slightly from it as well as from the negation of Safe_Last. Emax and Safe_Emax had relatively few uses in Ada 83; T'Safe_Emax can be computed in the revised language as Integer'Min(T'Exponent(T'Safe_First), T'Exponent(T'Safe_Last)). 72.e

Implementations are encouraged to eliminate the incompatibilities discussed here by retaining the old attributes, during a transition period, in the form of implementation-defined attributes with their former values. 72.f

Extensions to Ada 83

The Model_Emin attribute is new. It is conceptually similar to the negation of Safe_Emax attribute of Ada 83, adjusted for the fact that the model numbers now have the hardware radix. It is a fundamental determinant, along with Model_Mantissa, of the set of model numbers of a type (see G.2.1). 72.g

The Denorm and Signed_Zeros attributes are new, as are all of the primitive function attributes. 72.h

Extensions to Ada 95

{*AI95-00388-01*} The Machine_Rounding attribute is new. 72.i/2

A.5.4 Attributes of Fixed Point Types

Static Semantics

The following *representation-oriented* attributes are defined for every subtype S of a fixed point type *T*. 1

S'Machine_Radix 2

Yields the radix of the hardware representation of the type *T*. The value of this attribute is of the type *universal_integer*.

S'Machine_Rounds 3

Yields the value True if rounding is performed on inexact results of every predefined operation that yields a result of the type *T*; yields the value False otherwise. The value of this attribute is of the predefined type Boolean.

S'Machine_Overflows 4

Yields the value True if overflow and divide-by-zero are detected and reported by raising Constraint_Error for every predefined operation that yields a result of the type *T*; yields the value False otherwise. The value of this attribute is of the predefined type Boolean.

Incompatibilities With Ada 83

The Mantissa, Large, Safe_Small, and Safe_Large attributes of fixed point types are removed from the language. 4.a

Implementations are encouraged to eliminate the resulting incompatibility by retaining these attributes, during a transition period, in the form of implementation-defined attributes with their former values. 4.b

Extensions to Ada 83

The Machine_Radix attribute is now allowed for fixed point types. It is also specifiable in an attribute definition clause (see F.1). 4.c

A.5.5 Big Numbers

1/5 {*AI12-0208-1*} Support is provided for integer arithmetic involving values larger than those supported by the target machine, and for arbitrary-precision real numbers.

Static Semantics

2/5 {*AI12-0208-1*} The library package Numerics.Big_Numbers has the following declaration:

3/5
```
package Ada.Numerics.Big_Numbers
   with Pure, Nonblocking, Global => null is
   subtype Field is Integer range 0 .. implementation-defined;
   subtype Number_Base is Integer range 2 .. 16;
end Ada.Numerics.Big_Numbers;
```

Extensions to Ada 2012

3.a/5 {*AI12-0208-1*} The package Numerics.Big_Numbers is new.

A.5.6 Big Integers

Static Semantics

1/5 {*AI12-0208-1*} {*AI12-0366-1*} The library package Numerics.Big_Numbers.Big_Integers has the following declaration:

2/5
```
with Ada.Strings.Text_Buffers;
package Ada.Numerics.Big_Numbers.Big_Integers
   with Preelaborate, Nonblocking, Global => in out synchronized is
```

3/5
```
   {AI12-0208-1} {AI12-0366-1} {AI12-0407-1}    type Big_Integer is private
        with Integer_Literal => From_Universal_Image,
             Put_Image => Put_Image;
```

4/5
```
   function Is_Valid (Arg : Big_Integer) return Boolean
      with Convention => Intrinsic;
```

4.a/5 **Discussion:** {*AI12-0005-1*} The result of Is_Valid on a default-initialized object of type Big_Integer is unspecified, analogous to the value of a Valid attribute_reference applied to a default-initialized object of an integer type (see 13.9.2). The language-provided functions in the Big_Integers package only return values for which Is_Valid is certain to be True.

5/5
```
   subtype Valid_Big_Integer is Big_Integer
      with Dynamic_Predicate => Is_Valid (Valid_Big_Integer),
           Predicate_Failure => (raise Program_Error);
```

6/5
```
   function "=" (L, R : Valid_Big_Integer) return Boolean;
   function "<" (L, R : Valid_Big_Integer) return Boolean;
   function "<=" (L, R : Valid_Big_Integer) return Boolean;
   function ">" (L, R : Valid_Big_Integer) return Boolean;
   function ">=" (L, R : Valid_Big_Integer) return Boolean;
```

7/5
```
   function To_Big_Integer (Arg : Integer) return Valid_Big_Integer;
```

8/5
```
   subtype Big_Positive is Big_Integer
      with Dynamic_Predicate => (if Is_Valid (Big_Positive)
                                 then Big_Positive > 0),
           Predicate_Failure => (raise Constraint_Error);
```

9/5
```
   subtype Big_Natural is Big_Integer
      with Dynamic_Predicate => (if Is_Valid (Big_Natural)
                                 then Big_Natural >= 0),
           Predicate_Failure => (raise Constraint_Error);
```

10/5
```
   function In_Range (Arg, Low, High : Valid_Big_Integer) return Boolean is
     (Low <= Arg and Arg <= High);
```

```
   function To_Integer (Arg : Valid_Big_Integer) return Integer
      with Pre => In_Range (Arg,
                            Low  => To_Big_Integer (Integer'First),
                            High => To_Big_Integer (Integer'Last))
                  or else raise Constraint_Error;
```
11/5

```
   generic
      type Int is range <>;
   package Signed_Conversions is
      function To_Big_Integer (Arg : Int) return Valid_Big_Integer;
      function From_Big_Integer (Arg : Valid_Big_Integer) return Int
         with Pre => In_Range (Arg,
                               Low  => To_Big_Integer (Int'First),
                               High => To_Big_Integer (Int'Last))
                     or else raise Constraint_Error;
   end Signed_Conversions;
```
12/5

```
   generic
      type Int is mod <>;
   package Unsigned_Conversions is
      function To_Big_Integer (Arg : Int) return Valid_Big_Integer;
      function From_Big_Integer (Arg : Valid_Big_Integer) return Int
         with Pre => In_Range (Arg,
                               Low  => To_Big_Integer (Int'First),
                               High => To_Big_Integer (Int'Last))
                     or else raise Constraint_Error;
   end Unsigned_Conversions;
```
13/5

```
   function To_String (Arg : Valid_Big_Integer;
                       Width : Field := 0;
                       Base  : Number_Base := 10) return String
      with Post => To_String'Result'First = 1;
```
14/5

```
   function From_String (Arg : String) return Valid_Big_Integer;
```
15/5

{*AI12-0407-1*}
```
   function From_Universal_Image (Arg : String) return
Valid_Big_Integer
      renames From_String;
```
16/5

```
   procedure Put_Image
     (Buffer : in out Ada.Strings.Text_Buffers.Root_Buffer_Type'Class;
      Arg    : in Valid_Big_Integer);
```
17/5

```
   function "+" (L : Valid_Big_Integer) return Valid_Big_Integer;
   function "-" (L : Valid_Big_Integer) return Valid_Big_Integer;
   function "abs" (L : Valid_Big_Integer) return Valid_Big_Integer;
   function "+" (L, R : Valid_Big_Integer) return Valid_Big_Integer;
   function "-" (L, R : Valid_Big_Integer) return Valid_Big_Integer;
   function "*" (L, R : Valid_Big_Integer) return Valid_Big_Integer;
   function "/" (L, R : Valid_Big_Integer) return Valid_Big_Integer;
   function "mod" (L, R : Valid_Big_Integer) return Valid_Big_Integer;
   function "rem" (L, R : Valid_Big_Integer) return Valid_Big_Integer;
   function "**" (L : Valid_Big_Integer; R : Natural)
      return Valid_Big_Integer;
   function Min (L, R : Valid_Big_Integer) return Valid_Big_Integer;
   function Max (L, R : Valid_Big_Integer) return Valid_Big_Integer;
```
18/5

```
   function Greatest_Common_Divisor
     (L, R : Valid_Big_Integer) return Big_Positive
     with Pre => (L /= 0 and R /= 0) or else raise Constraint_Error;
```
19/5

```
private
   ... -- not specified by the language
end Ada.Numerics.Big_Numbers.Big_Integers;
```
20/5

{*AI12-0208-1*} {*AI12-0366-1*} To_String and From_String behave analogously to the Put and Get procedures defined in Text_IO.Integer_IO (in particular, with respect to the interpretation of the Width and Base parameters) except that Constraint_Error, not Data_Error, is propagated in error cases and the result of a call to To_String with a Width parameter of 0 and a nonnegative Arg parameter does not include a leading blank. Put_Image calls To_String (passing in the default values for the Width and Base 21/5

parameters), prepends a leading blank if the argument is nonnegative, and writes the resulting value to the buffer using Text_Buffers.Put.

22/5 {*AI12-0208-1*} The other functions have their usual mathematical meanings.

23/5 {*AI12-0208-1*} {*AI12-0366-1*} The type Big_Integer needs finalization (see 7.6).

Dynamic Semantics

24/5 {*AI12-0208-1*} {*AI12-0366-1*} For purposes of determining whether predicate checks are performed as part of default initialization, the type Big_Integer is considered to have a subcomponent that has a default_expression.

24.a/5 **Ramification:** {*AI12-0005-1*} {*AI12-0208-1*} This means that the elaboration of

24.b/5
```
Default_Initialized_Object : Valid_Big_Integer;
```

24.c/5 either produces a value for which Is_Valid is True. or it propagates Program_Error.

Implementation Requirements

25/5 {*AI12-0208-1*} {*AI12-0366-1*} No storage associated with a Big_Integer object shall be lost upon assignment or scope exit.

25.a/5 **Implementation Note:** {*AI12-0208-1*} The "No storage ... shall be lost" requirement does not preclude implementation techniques such as caching or unique number tables.

Extensions to Ada 2012

25.b/5 {*AI12-0208-1*} {*AI12-0366-1*} The package Numerics.Big_Numbers.Big_Integers is new.

A.5.7 Big Reals

Static Semantics

1/5 {*AI12-0208-1*} {*AI12-0366-1*} The library package Numerics.Big_Numbers.Big_Reals has the following declaration:

2/5
```
with Ada.Numerics.Big_Numbers.Big_Integers;
   use all type Big_Integers.Big_Integer;
with Ada.Strings.Text_Buffers;
package Ada.Numerics.Big_Numbers.Big_Reals
   with Preelaborate, Nonblocking, Global => in out synchronized is
```

3/5
```
   {AI12-0208-1} {AI12-0366-1} {AI12-0407-1}    type Big_Real is private
         with Real_Literal => From_Universal_Image,
              Put_Image => Put_Image;
```

4/5
```
      function Is_Valid (Arg : Big_Real) return Boolean
         with Convention => Intrinsic;
```

4.a/5 **Discussion:** {*AI12-0005-1*} The result of Is_Valid on a default-initialized object of type Big_Real is unspecified, analogous to the value of a Valid attribute_reference applied to a default-initialized object of a real type (see 13.9.2). The language-provided functions in the Big_Reals package only return values for which Is_Valid is certain to be True.

5/5
```
      subtype Valid_Big_Real is Big_Real
         with Dynamic_Predicate => Is_Valid (Valid_Big_Real),
              Predicate_Failure => raise Program_Error;
```

6/5
```
      function "/" (Num, Den : Big_Integers.Valid_Big_Integer)
         return Valid_Big_Real
         with Pre => Den /= 0
                     or else raise Constraint_Error;
```

7/5
```
      function Numerator
         (Arg : Valid_Big_Real) return Big_Integers.Valid_Big_Integer
        with Post => (if Arg = 0.0 then Numerator'Result = 0);
```

Reason: The postcondition of Numerator cannot be complete as it cannot mention Denominator. Since the postcondition of Denominator uses Numerator, we would get an infinite mutual recursion if both postconditions are enabled. The postcondition of Denominator serves as the postcondition for Numerator as well unless Arg = 0.0. 7.a/5

```
function Denominator (Arg : Valid_Big_Real)                                    8/5
   return Big_Integers.Big_Positive
   with Post =>
     (if Arg = 0.0 then Denominator'Result = 1
      else Big_Integers.Greatest_Common_Divisor
             (Numerator (Arg), Denominator'Result) = 1);

function To_Big_Real (Arg : Big_Integers.Valid_Big_Integer)                    9/5
   return Valid_Big_Real is (Arg / 1);

function To_Real (Arg : Integer) return Valid_Big_Real is                      10/5
   (Big_Integers.To_Big_Integer (Arg) / 1);

function "=" (L, R : Valid_Big_Real) return Boolean;                           11/5
function "<" (L, R : Valid_Big_Real) return Boolean;
function "<=" (L, R : Valid_Big_Real) return Boolean;
function ">" (L, R : Valid_Big_Real) return Boolean;
function ">=" (L, R : Valid_Big_Real) return Boolean;

function In_Range (Arg, Low, High : Valid_Big_Real) return Boolean is          12/5
   (Low <= Arg and Arg <= High);

generic                                                                        13/5
   type Num is digits <>;
package Float_Conversions is
   function To_Big_Real (Arg : Num) return Valid_Big_Real;
   function From_Big_Real (Arg : Valid_Big_Real) return Num
      with Pre => In_Range (Arg,
                            Low  => To_Big_Real (Num'First),
                            High => To_Big_Real (Num'Last))
                  or else (raise Constraint_Error);
end Float_Conversions;

generic                                                                        14/5
   type Num is delta <>;
package Fixed_Conversions is
   function To_Big_Real (Arg : Num) return Valid_Big_Real;
   function From_Big_Real (Arg : Valid_Big_Real) return Num
      with Pre => In_Range (Arg,
                            Low  => To_Big_Real (Num'First),
                            High => To_Big_Real (Num'Last))
                  or else (raise Constraint_Error);
end Fixed_Conversions;

function To_String (Arg  : Valid_Big_Real;                                     15/5
                    Fore : Field := 2;
                    Aft  : Field := 3;
                    Exp  : Field := 0) return String
   with Post => To_String'Result'First = 1;

function From_String (Arg   : String) return Valid_Big_Real;                   16/5

{AI12-0407-1}    function From_Universal_Image (Arg : String) return Valid_Big_Real   17/5
   renames From_String;

{AI12-0407-1}    function From_Universal_Image (Num, Den : String)             18/5
   return Valid_Big_Real is
      (Big_Integers.From_Universal_Image (Num) /
       Big_Integers.From_Universal_Image (Den));

function To_Quotient_String (Arg : Valid_Big_Real) return String is            19/5
   (To_String (Numerator (Arg)) & " / " & To_String (Denominator (Arg)));
function From_Quotient_String (Arg : String) return Valid_Big_Real;

procedure Put_Image                                                            20/5
  (Buffer : in out Ada.Strings.Text_Buffers.Root_Buffer_Type'Class;
   Arg    : in Valid_Big_Real);
```

21/5
```
      function "+" (L : Valid_Big_Real) return Valid_Big_Real;
      function "-" (L : Valid_Big_Real) return Valid_Big_Real;
      function "abs" (L : Valid_Big_Real) return Valid_Big_Real;
      function "+" (L, R : Valid_Big_Real) return Valid_Big_Real;
      function "-" (L, R : Valid_Big_Real) return Valid_Big_Real;
      function "*" (L, R : Valid_Big_Real) return Valid_Big_Real;
      function "/" (L, R : Valid_Big_Real) return Valid_Big_Real;
      function "**" (L : Valid_Big_Real; R : Integer)
         return Valid_Big_Real;
      function Min (L, R : Valid_Big_Real) return Valid_Big_Real;
      function Max (L, R : Valid_Big_Real) return Valid_Big_Real;
```

22/5
```
   private
      ... -- not specified by the language
   end Ada.Numerics.Big_Numbers.Big_Reals;
```

23/5 {*AI12-0208-1*} {*AI12-0366-1*} To_String and From_String behave analogously to the Put and Get procedures defined in Text_IO.Float_IO (in particular, with respect to the interpretation of the Fore, Aft, and Exp parameters), except that Constraint_Error (not Data_Error) is propagated in error cases. From_Quotient_String implements the inverse function of To_Quotient_String; Constraint_Error is propagated in error cases. Put_Image calls To_String, and writes the resulting value to the buffer using Text_Buffers.Put.

24/5 {*AI12-0208-1*} For an instance of Float_Conversions or Fixed_Conversions, To_Big_Real is exact (that is, the result represents exactly the same mathematical value as the argument) and From_Big_Real is subject to the same precision rules as a type conversion of a value of type T to the target type Num, where T is a hypothetical floating point type whose model numbers include all of the model numbers of Num as well as the exact mathematical value of the argument.

25/5 {*AI12-0208-1*} The other functions have their usual mathematical meanings.

26/5 {*AI12-0208-1*} {*AI12-0366-1*} The type Big_Real needs finalization (see 7.6).

Dynamic Semantics

27/5 {*AI12-0208-1*} {*AI12-0366-1*} For purposes of determining whether predicate checks are performed as part of default initialization, the type Big_Real is considered to have a subcomponent that has a default_expression.

27.a/5 **Ramification:** {*AI12-0005-1*} {*AI12-0208-1*} This means that the elaboration of

27.b/5
```
Default_Initialized_Object : Valid_Big_Real;
```

27.c/5 either produces a value for which Is_Valid is True. or it propagates Program_Error.

Implementation Requirements

28/5 {*AI12-0208-1*} {*AI12-0366-1*} No storage associated with a Big_Real object shall be lost upon assignment or scope exit.

28.a/5 **Implementation Note:** {*AI12-0208-1*} The “No storage ... shall be lost” requirement does not preclude implementation techniques such as caching or unique number tables.

Extensions to Ada 2012

28.b/5 {*AI12-0208-1*} {*AI12-0366-1*} The package Numerics.Big_Numbers.Big_Reals is new.

A.6 Input-Output

1/5 {*AI95-00285-01*} {*AI12-0445-1*} [Input-output is provided through language-defined packages, each of which is a child of the root package Ada. The generic packages Sequential_IO and Direct_IO define input-output operations applicable to files containing elements of a given type. The generic package Storage_IO supports reading from and writing to an in-memory buffer. Additional operations for text

input-output are supplied in the packages Text_IO, Wide_Text_IO, and Wide_Wide_Text_IO. Heterogeneous input-output is provided through the child packages Streams.Stream_IO and Text_IO.-Text_Streams (see also 13.13). The package IO_Exceptions defines the exceptions used by the predefined input-output packages.]

Inconsistencies With Ada 83

1.a The introduction of Append_File as a new element of the enumeration type File_Mode in Sequential_IO and Text_IO, and the introduction of several new declarations in Text_IO, may result in name clashes in the presence of **use** clauses.

Extensions to Ada 83

1.b Text_IO enhancements (Get_Immediate, Look_Ahead, Standard_Error, Modular_IO, Decimal_IO), Wide_Text_IO, and the stream input-output facilities are new in Ada 95.

Wording Changes from Ada 83

1.c RM83-14.6, “Low Level Input-Output”, is removed. This has no semantic effect, since the package was entirely implementation defined, nobody actually implemented it, and if they did, they can always provide it as a vendor-supplied package.

Wording Changes from Ada 95

1.d/2 {*AI95-00285-01*} Included package Wide_Wide_Text_IO in this description.

A.7 External Files and File Objects

Static Semantics

1 Values input from the external environment of the program, or output to the external environment, are considered to occupy *external files*. An external file can be anything external to the program that can produce a value to be read or receive a value to be written. An external file is identified by a string (the *name*). A second string (the *form*) gives further system-dependent characteristics that may be associated with the file, such as the physical organization or access rights. The conventions governing the interpretation of such strings shall be documented.

2/3 {*AI05-0299-1*} Input and output operations are expressed as operations on objects of some *file type*, rather than directly in terms of the external files. In the remainder of this clause, the term *file* is always used to refer to a file object; the term *external file* is used otherwise.

3 Input-output for sequential files of values of a single element type is defined by means of the generic package Sequential_IO. In order to define sequential input-output for a given element type, an instantiation of this generic unit, with the given type as actual parameter, has to be declared. The resulting package contains the declaration of a file type (called File_Type) for files of such elements, as well as the operations applicable to these files, such as the Open, Read, and Write procedures.

4/2 {*AI95-00285-01*} Input-output for direct access files is likewise defined by a generic package called Direct_IO. Input-output in human-readable form is defined by the (nongeneric) packages Text_IO for Character and String data, Wide_Text_IO for Wide_Character and Wide_String data, and Wide_Wide_Text_IO for Wide_Wide_Character and Wide_Wide_String data. Input-output for files containing streams of elements representing values of possibly different types is defined by means of the (nongeneric) package Streams.Stream_IO.

5 Before input or output operations can be performed on a file, the file first has to be associated with an external file. While such an association is in effect, the file is said to be *open*, and otherwise the file is said to be *closed*.

6 The language does not define what happens to external files after the completion of the main program and all the library tasks (in particular, if corresponding files have not been closed). The effect of input-output for access types is unspecified.

7 An open file has a *current mode*, which is a value of one of the following enumeration types:

8
```
type File_Mode is (In_File, Inout_File, Out_File);  -- for Direct_IO
```

9 These values correspond respectively to the cases where only reading, both reading and writing, or only writing are to be performed.

10/2
```
{AI95-00285-01} type File_Mode is (In_File, Out_File, Append_File);
-- for Sequential_IO, Text_IO, Wide_Text_IO, Wide_Wide_Text_IO, and Stream_IO
```

11 These values correspond respectively to the cases where only reading, only writing, or only appending are to be performed.

12 The mode of a file can be changed.

13/5 {*AI95-00285-01*} {*AI12-0449-1*} Several file management operations are common to Sequential_IO, Direct_IO, Text_IO, Wide_Text_IO, and Wide_Wide_Text_IO. These operations are described in A.8.2 for sequential and direct files. Any additional effects concerning text input-output are described in A.10.2.

14/5 {*AI05-0299-1*} {*AI12-0449-1*} The exceptions that can be propagated by the execution of an input-output subprogram are defined in the package IO_Exceptions; the situations in which they can be propagated are described following the description of the subprogram (and in A.13). The exceptions Storage_Error and Program_Error may be propagated. (Program_Error can only be propagated due to errors made by the caller of the subprogram.) Finally, exceptions can be propagated in certain implementation-defined situations.

14.a/2 *This paragraph was deleted.*

14.b/2 **Discussion:** The last sentence here is referring to the documentation requirements in A.13, “Exceptions in Input-Output”, and the documentation summary item is provided there.

15/2 NOTE 1 {*AI95-00285-01*} Each instantiation of the generic packages Sequential_IO and Direct_IO declares a different type File_Type. In the case of Text_IO, Wide_Text_IO, Wide_Wide_Text_IO, and Streams.Stream_IO, the corresponding type File_Type is unique.

16/5 NOTE 2 {*AI12-0440-1*} A bidirectional device can often be modeled as two sequential files associated with the device, one of mode In_File, and one of mode Out_File. An implementation can restrict the number of files that can be associated with a given external file.

Wording Changes from Ada 95

16.a/2 {*AI95-00285-01*} Included package Wide_Wide_Text_IO in this description.

A.8 Sequential and Direct Files

Static Semantics

1/2 {*AI95-00283-01*} Two kinds of access to external files are defined in this subclause: *sequential access* and *direct access*. The corresponding file types and the associated operations are provided by the generic packages Sequential_IO and Direct_IO. A file object to be used for sequential access is called a *sequential file*, and one to be used for direct access is called a *direct file*. Access to *stream file*s is described in A.12.1.

2 For sequential access, the file is viewed as a sequence of values that are transferred in the order of their appearance (as produced by the program or by the external environment). When the file is opened with mode In_File or Out_File, transfer starts respectively from or to the beginning of the file. When the file is opened with mode Append_File, transfer to the file starts after the last element of the file.

Discussion: Adding stream I/O necessitates a review of the terminology. In Ada 83, `sequential' implies both the access method (purely sequential — that is, no indexing or positional access) and homogeneity. Direct access includes purely sequential access and indexed access, as well as homogeneity. In Ada 95, streams allow purely sequential access but also positional access to an individual element, and are heterogeneous. We considered generalizing the notion of `sequential file' to include both Sequential_IO and Stream_IO files, but since streams allow positional access it seems misleading to call them sequential files. Or, looked at differently, if the criterion for calling something a sequential file is whether it permits (versus requires) purely sequential access, then one could just as soon regard a Direct_IO file as a sequential file. 2.a

It seems better to regard `sequential file' as meaning `only permitting purely sequential access'; hence we have decided to supplement `sequential access' and `direct access' with a third category, informally called `access to streams'. (We decided against the term `stream access' because of possible confusion with the Stream_Access type declared in one of the stream packages.) 2.b

For direct access, the file is viewed as a set of elements occupying consecutive positions in linear order; a value can be transferred to or from an element of the file at any selected position. The position of an element is specified by its *index*, which is a number, greater than zero, of the implementation-defined integer type Count. The first element, if any, has index one; the index of the last element, if any, is called the *current size*; the current size is zero if there are no elements. The current size is a property of the external file. 3

An open direct file has a *current index*, which is the index that will be used by the next read or write operation. When a direct file is opened, the current index is set to one. The current index of a direct file is a property of a file object, not of an external file. 4

Wording Changes from Ada 95

{*AI95-00283-01*} Italicized “stream file” to clarify that this is another kind of file. 4.a/2

A.8.1 The Generic Package Sequential_IO

Static Semantics

The generic library package Sequential_IO has the following declaration: 1

```
{AI12-0302-1} with Ada.IO_Exceptions;                                                    2/5
generic
   type Element_Type(<>) is private;
package Ada.Sequential_IO
   with Global => in out synchronized is

   type File_Type is limited private;                                                    3

   type File_Mode is (In_File, Out_File, Append_File);                                   4

   -- File management                                                                    5

   procedure Create(File : in out File_Type;                                             6
                    Mode : in File_Mode := Out_File;
                    Name : in String := "";
                    Form : in String := "");

   procedure Open  (File : in out File_Type;                                             7
                    Mode : in File_Mode;
                    Name : in String;
                    Form : in String := "");

   procedure Close (File : in out File_Type);                                            8
   procedure Delete(File : in out File_Type);
   procedure Reset (File : in out File_Type; Mode : in File_Mode);
   procedure Reset (File : in out File_Type);

   function Mode   (File : in File_Type) return File_Mode;                               9
   function Name   (File : in File_Type) return String;
   function Form   (File : in File_Type) return String;

   function Is_Open(File : in File_Type) return Boolean;                                 10
```

```
10.1/5      {AI12-0130-1} {AI12-0302-1}    procedure Flush (File : in File_Type)
                with Global => overriding in out File;
11             -- Input and output operations
12/5        {AI12-0302-1}    procedure Read  (File : in File_Type; Item : out Element_Type)
                with Global => overriding in out File;
            procedure Write (File : in File_Type; Item : in Element_Type)
                with Global => overriding in out File;
13          function End_Of_File(File : in File_Type) return Boolean;
14          -- Exceptions
15          Status_Error : exception renames IO_Exceptions.Status_Error;
            Mode_Error   : exception renames IO_Exceptions.Mode_Error;
            Name_Error   : exception renames IO_Exceptions.Name_Error;
            Use_Error    : exception renames IO_Exceptions.Use_Error;
            Device_Error : exception renames IO_Exceptions.Device_Error;
            End_Error    : exception renames IO_Exceptions.End_Error;
            Data_Error   : exception renames IO_Exceptions.Data_Error;
15.1/5      {AI12-0021-1}    package Wide_File_Names is
15.2/5            -- File management
15.3/5            procedure Create(File : in out File_Type;
                                   Mode : in File_Mode := Out_File;
                                   Name : in Wide_String := "";
                                   Form : in Wide_String := "");
15.4/5            procedure Open  (File : in out File_Type;
                                   Mode : in File_Mode;
                                   Name : in Wide_String;
                                   Form : in Wide_String := "");
15.5/5            function Name   (File : in File_Type) return Wide_String;
15.6/5            function Form   (File : in File_Type) return Wide_String;
15.7/5         end Wide_File_Names;
15.8/5      {AI12-0021-1}    package Wide_Wide_File_Names is
15.9/5            -- File management
15.10/5           procedure Create(File : in out File_Type;
                                   Mode : in File_Mode := Out_File;
                                   Name : in Wide_Wide_String := "";
                                   Form : in Wide_Wide_String := "");
15.11/5           procedure Open  (File : in out File_Type;
                                   Mode : in File_Mode;
                                   Name : in Wide_Wide_String;
                                   Form : in Wide_Wide_String := "");
15.12/5           function Name   (File : in File_Type) return Wide_Wide_String;
15.13/5           function Form   (File : in File_Type) return Wide_Wide_String;
15.14/5        end Wide_Wide_File_Names;
16          private
               ... -- not specified by the language
            end Ada.Sequential_IO;
```

17/2 {*AI95-00360-01*} The type File_Type needs finalization (see 7.6) in every instantiation of Sequential_IO.

Incompatibilities With Ada 83

17.a The new enumeration element Append_File may introduce upward incompatibilities. It is possible that a program based on the assumption that File_Mode'Last = Out_File will be illegal (e.g., case statement choice coverage) or execute with a different effect in Ada 95.

17.a.1/2 *This paragraph was deleted.* {*8652/0097*} {*AI95-00115-01*} {*AI95-00344-01*}

Incompatibilities With Ada 95

{*AI95-00360-01*} **Amendment Correction:** File_Type in an instance of Sequential_IO is defined to need finalization. If the restriction No_Nested_Finalization (see D.7) applies to the partition, and File_Type does not have a controlled part, it will not be allowed in local objects in Ada 2005 whereas it would be allowed in original Ada 95. Such code is not portable, as another Ada compiler may have a controlled part in File_Type, and thus would be illegal. 17.b/2

Incompatibilities With Ada 2012

{*AI12-0130-1*} {*AI05-0005-1*} **Corrigendum:** The Flush procedure is newly added to Ada.Sequential_IO. Therefore, a use clause conflict is possible; see the introduction of Annex A for more on this topic. 17.c/5

{*AI12-0021-1*} The Wide_File_Names and Wide_Wide_File_Names nested packages are newly added to Ada.Sequential_IO. Therefore, a use clause conflict is possible; see the introduction of Annex A for more on this topic. 17.d/5

A.8.2 File Management

Static Semantics

{*AI12-0449-1*} The procedures and functions described in this subclause provide for the control of external files; their declarations are repeated in each of the packages for sequential, direct, text, and stream input-output. For text input-output, the procedures Create, Open, and Reset have additional effects described in A.10.2. 1/5

```
procedure Create(File : in out File_Type;                                    2
                 Mode : in File_Mode := default_mode;
                 Name : in String := "";
                 Form : in String := "");
```

{*AI95-00283-01*} Establishes a new external file, with the given name and form, and associates this external file with the given file. The given file is left open. The current mode of the given file is set to the given access mode. The default access mode is the mode Out_File for sequential, stream, and text input-output; it is the mode Inout_File for direct input-output. For direct access, the size of the created file is implementation defined. 3/2

Ramification: {*AI12-0005-1*} For a direct file, the initial value of current index is 1 (see A.8). 3.a/4

A null string for Name specifies an external file that is not accessible after the completion of the main program (a temporary file). A null string for Form specifies the use of the default options of the implementation for the external file. 4

The exception Status_Error is propagated if the given file is already open. The exception Name_Error is propagated if the string given as Name does not allow the identification of an external file. The exception Use_Error is propagated if, for the specified mode, the external environment does not support creation of an external file with the given name (in the absence of Name_Error) and form. 5

```
procedure Open(File : in out File_Type;                                      6
               Mode : in File_Mode;
               Name : in String;
               Form : in String := "");
```

Associates the given file with an existing external file having the given name and form, and sets the current mode of the given file to the given mode. The given file is left open. 7

Ramification: {*AI12-0005-1*} For a direct file, the initial value of current index is 1 (see A.8). 7.a/4

The exception Status_Error is propagated if the given file is already open. The exception Name_Error is propagated if the string given as Name does not allow the identification of an external file; in particular, this exception is propagated if no external file with the given name exists. The exception Use_Error is propagated if, for the specified mode, the external 8

environment does not support opening for an external file with the given name (in the absence of Name_Error) and form.

9 `procedure Close(File : in out File_Type);`

10 Severs the association between the given file and its associated external file. The given file is left closed. In addition, for sequential files, if the file being closed has mode Out_File or Append_File, then the last element written since the most recent open or reset is the last element that can be read from the file. If no elements have been written and the file mode is Out_File, then the closed file is empty. If no elements have been written and the file mode is Append_File, then the closed file is unchanged.

11 The exception Status_Error is propagated if the given file is not open.

12 `procedure Delete(File : in out File_Type);`

13 Deletes the external file associated with the given file. The given file is closed, and the external file ceases to exist.

14 The exception Status_Error is propagated if the given file is not open. The exception Use_Error is propagated if deletion of the external file is not supported by the external environment.

15
```
procedure Reset(File : in out File_Type; Mode : in File_Mode);
procedure Reset(File : in out File_Type);
```

16/2 {*AI95-00085-01*} Resets the given file so that reading from its elements can be restarted from the beginning of the external file (for modes In_File and Inout_File), and so that writing to its elements can be restarted at the beginning of the external file (for modes Out_File and Inout_File) or after the last element of the external file (for mode Append_File). In particular, for direct access this means that the current index is set to one. If a Mode parameter is supplied, the current mode of the given file is set to the given mode. In addition, for sequential files, if the given file has mode Out_File or Append_File when Reset is called, the last element written since the most recent open or reset is the last element that can be read from the external file. If no elements have been written and the file mode is Out_File, the reset file is empty. If no elements have been written and the file mode is Append_File, then the reset file is unchanged.

17 The exception Status_Error is propagated if the file is not open. The exception Use_Error is propagated if the external environment does not support resetting for the external file and, also, if the external environment does not support resetting to the specified mode for the external file.

18 `function Mode(File : in File_Type) return File_Mode;`

19 Returns the current mode of the given file.

20 The exception Status_Error is propagated if the file is not open.

21 `function Name(File : in File_Type) return String;`

22/2 {*AI95-00248-01*} Returns a string which uniquely identifies the external file currently associated with the given file (and may thus be used in an Open operation).

22.a/2 **Discussion:** {*AI95-00248-01*} Retrieving the full path can be accomplished by passing the result of Name to Directories.Full_Name (see A.16). It is important to drop the requirement on Name, as the only way to accomplish this requirement given that the current directory can be changed with package Directories is to store the full path when the file is opened. That's expensive, and it's better for users that need the full path to explicitly request it.

23 The exception Status_Error is propagated if the given file is not open. The exception Use_Error is propagated if the associated external file is a temporary file that cannot be opened by any name.

```
function Form(File : in File_Type) return String;
```

Returns the form string for the external file currently associated with the given file. If an external environment allows alternative specifications of the form (for example, abbreviations using default options), the string returned by the function should correspond to a full specification (that is, it should indicate explicitly all options selected, including default options).

The exception Status_Error is propagated if the given file is not open.

```
function Is_Open(File : in File_Type) return Boolean;
```

{*AI05-0264-1*} Returns True if the file is open (that is, if it is associated with an external file); otherwise, returns False.

{*AI12-0130-1*}
```
procedure Flush(File : in File_Type);
```

The Flush procedure synchronizes the external file with the internal file (by flushing any internal buffers) without closing the file. For a direct file, the current index is unchanged; for a stream file (see A.12.1), the current position is unchanged.

The exception Status_Error is propagated if the file is not open. The exception Mode_Error is propagated if the mode of the file is In_File.

{*AI12-0021-1*} The nested package Wide_File_Names provides operations equivalent to the operations of the same name of the outer package except that Wide_String is used instead of String for the name and form of the external file.

Implementation Note: {*AI12-0021-1*} The expectation is that if one opens a file with this subpackage and then requests the name with Name from this subpackage, the result will include the same Wide_Characters that were used to open the file (rather than some encoded form). Since file names are completely implementation-defined, we cannot say this normatively. We have no expectations when retrieving the name of a file opened with this package using the String Name. Similar considerations apply to the nested package Wide_Wide_File_Names (see below).

{*AI12-0021-1*} The nested package Wide_Wide_File_Names provides operations equivalent to the operations of the same name of the outer package except that Wide_Wide_String is used instead of String for the name and form of the external file.

Implementation Permissions

An implementation may propagate Name_Error or Use_Error if an attempt is made to use an I/O feature that cannot be supported by the implementation due to limitations in the external environment. Any such restriction should be documented.

Wording Changes from Ada 95

{*AI95-00085-01*} Clarified that Reset affects and depends on the external file.

{*AI95-00248-01*} Removed the requirement for Name to return a full path; this is now accomplished by Directories.Full_Name(Name(File)) (see A.16). This is not documented as an inconsistency, because there is no requirement for implementations to change — the Ada 95 behavior is still allowed, it just is no longer required.

{*AI95-00283-01*} Added text to specify the default mode for a stream file.

Wording Changes from Ada 2012

{*AI12-0130-1*} Procedure Flush is now defined here, so it can be used for all of the I/O packages.

{*AI12-0021-1*} The nested Wide_File_Names and Wide_Wide_File_Names packages are now described here.

A.8.3 Sequential Input-Output Operations

Static Semantics

1 The operations available for sequential input and output are described in this subclause. The exception Status_Error is propagated if any of these operations is attempted for a file that is not open.

2
```
procedure Read(File : in File_Type; Item : out Element_Type);
```

3 Operates on a file of mode In_File. Reads an element from the given file, and returns the value of this element in the Item parameter.

3.a **Discussion:** We considered basing Sequential_IO.Read on Element_Type'Read from an implicit stream associated with the sequential file. However, Element_Type'Read is a type-related attribute, whereas Sequential_IO should take advantage of the particular constraints of the actual subtype corresponding to Element_Type to minimize the size of the external file. Furthermore, forcing the implementation of Sequential_IO to be based on Element_Type'Read would create an upward incompatibility since existing data files written by an Ada 83 program using Sequential_IO might not be readable by the identical program built with an Ada 95 implementation of Sequential_IO.

3.b An Ada 95 implementation might still use an implementation-defined attribute analogous to 'Read to implement the procedure Read, but that attribute will likely have to be subtype-specific rather than type-related, and it need not be user-specifiable. Such an attribute will presumably be needed to implement the generic package Storage_IO (see A.9).

4 The exception Mode_Error is propagated if the mode is not In_File. The exception End_Error is propagated if no more elements can be read from the given file. The exception Data_Error can be propagated if the element read cannot be interpreted as a value of the subtype Element_Type (see A.13, “Exceptions in Input-Output”).

4.a **Discussion:** Data_Error need not be propagated if the check is too complex. See A.13, “Exceptions in Input-Output”.

5
```
procedure Write(File : in File_Type; Item : in Element_Type);
```

6 Operates on a file of mode Out_File or Append_File. Writes the value of Item to the given file.

7 The exception Mode_Error is propagated if the mode is not Out_File or Append_File. The exception Use_Error is propagated if the capacity of the external file is exceeded.

8
```
function End_Of_File(File : in File_Type) return Boolean;
```

9/3 {*AI05-0264-1*} Operates on a file of mode In_File. Returns True if no more elements can be read from the given file; otherwise, returns False.

10 The exception Mode_Error is propagated if the mode is not In_File.

A.8.4 The Generic Package Direct_IO

Static Semantics

1 The generic library package Direct_IO has the following declaration:

2/5
```
{AI12-0302-1} with Ada.IO_Exceptions;
generic
   type Element_Type is private;
package Ada.Direct_IO
   with Global => in out synchronized is

3     type File_Type is limited private;

4     type File_Mode is (In_File, Inout_File, Out_File);
      type Count     is range 0 .. implementation-defined;
      subtype Positive_Count is Count range 1 .. Count'Last;

5     -- File management
```

```
   procedure Create(File : in out File_Type;                                    6
                    Mode : in File_Mode := Inout_File;
                    Name : in String := "";
                    Form : in String := "");

   procedure Open  (File : in out File_Type;                                    7
                    Mode : in File_Mode;
                    Name : in String;
                    Form : in String := "");

   procedure Close (File : in out File_Type);                                   8
   procedure Delete(File : in out File_Type);
   procedure Reset (File : in out File_Type; Mode : in File_Mode);
   procedure Reset (File : in out File_Type);

   function Mode   (File : in File_Type) return File_Mode;                      9
   function Name   (File : in File_Type) return String;
   function Form   (File : in File_Type) return String;

   function Is_Open(File : in File_Type) return Boolean;                        10

{AI12-0130-1} {AI12-0302-1}    procedure Flush (File : in File_Type)          10.1/5
      with Global => overriding in out File;

   -- Input and output operations                                             11

{AI12-0302-1}    procedure Read (File : in File_Type; Item : out Element_Type; 12/5
                                 From : in Positive_Count)
      with Global => overriding in out File;
   procedure Read (File : in File_Type; Item : out Element_Type)
      with Global => overriding in out File;

{AI12-0302-1}    procedure Write(File : in File_Type; Item : in  Element_Type; 13/5
                                 To   : in Positive_Count)
      with Global => overriding in out File;
   procedure Write(File : in File_Type; Item : in Element_Type)
      with Global => overriding in out File;

18.14/5
```
   end Wide_Wide_File_Names;
```
19
```
private
   ... -- not specified by the language
end Ada.Direct_IO;
```

19.a **Reason:** The Element_Type formal of Direct_IO does not have an unknown_discriminant_part (unlike Sequential_IO) so that the implementation can make use of the ability to declare uninitialized variables of the type.

20/2 {*AI95-00360-01*} The type File_Type needs finalization (see 7.6) in every instantiation of Direct_IO.

20.a.1/2 *This paragraph was deleted.*{*8652/0097*} {*AI95-00115-01*} {*AI95-00344-01*}

Incompatibilities With Ada 95

20.a/2 {*AI95-00360-01*} **Amendment Correction:** File_Type in an instance of Direct_IO is defined to need finalization. If the restriction No_Nested_Finalization (see D.7) applies to the partition, and File_Type does not have a controlled part, it will not be allowed in local objects in Ada 2005 whereas it would be allowed in original Ada 95. Such code is not portable, as another Ada compiler may have a controlled part in File_Type, and thus would be illegal.

Incompatibilities With Ada 2012

20.b/5 {*AI12-0130-1*} {*AI05-0005-1*} **Corrigendum:** The Flush procedure is newly added to Ada.Direct_IO. Therefore, a use clause conflict is possible; see the introduction of Annex A for more on this topic.

20.c/5 {*AI12-0021-1*} The Wide_File_Names and Wide_Wide_File_Names nested packages are newly added to Ada.Direct_IO. Therefore, a use clause conflict is possible; see the introduction of Annex A for more on this topic.

A.8.5 Direct Input-Output Operations

Static Semantics

1 The operations available for direct input and output are described in this subclause. The exception Status_Error is propagated if any of these operations is attempted for a file that is not open.

2
```
   procedure Read(File : in File_Type; Item : out Element_Type;
                                       From : in  Positive_Count);
   procedure Read(File : in File_Type; Item : out Element_Type);
```

3 Operates on a file of mode In_File or Inout_File. In the case of the first form, sets the current index of the given file to the index value given by the parameter From. Then (for both forms) returns, in the parameter Item, the value of the element whose position in the given file is specified by the current index of the file; finally, increases the current index by one.

4 The exception Mode_Error is propagated if the mode of the given file is Out_File. The exception End_Error is propagated if the index to be used exceeds the size of the external file. The exception Data_Error can be propagated if the element read cannot be interpreted as a value of the subtype Element_Type (see A.13).

```
procedure Write(File : in File_Type; Item : in Element_Type;                    5
                                     To   : in Positive_Count);
procedure Write(File : in File_Type; Item : in Element_Type);
```

Operates on a file of mode Inout_File or Out_File. In the case of the first form, sets the index of the given file to the index value given by the parameter To. Then (for both forms) gives the value of the parameter Item to the element whose position in the given file is specified by the current index of the file; finally, increases the current index by one. 6

The exception Mode_Error is propagated if the mode of the given file is In_File. The exception Use_Error is propagated if the capacity of the external file is exceeded. 7

```
procedure Set_Index(File : in File_Type; To : in Positive_Count);               8
```

Operates on a file of any mode. Sets the current index of the given file to the given index value (which may exceed the current size of the file). 9

```
function Index(File : in File_Type) return Positive_Count;                      10
```

Operates on a file of any mode. Returns the current index of the given file. 11

```
function Size(File : in File_Type) return Count;                                12
```

Operates on a file of any mode. Returns the current size of the external file that is associated with the given file. 13

```
function End_Of_File(File : in File_Type) return Boolean;                       14
```

{*AI05-0264-1*} Operates on a file of mode In_File or Inout_File. Returns True if the current index exceeds the size of the external file; otherwise, returns False. 15/3

The exception Mode_Error is propagated if the mode of the given file is Out_File. 16

NOTE Append_File mode is not supported for the generic package Direct_IO. 17

A.9 The Generic Package Storage_IO

The generic package Storage_IO provides for reading from and writing to an in-memory buffer. This generic package supports the construction of user-defined input-output packages. 1

Reason: This package exists to allow the portable construction of user-defined direct-access-oriented input-output packages. The Write procedure writes a value of type Element_Type into a Storage_Array of size Buffer_Size, flattening out any implicit levels of indirection used in the representation of the type. The Read procedure reads a value of type Element_Type from the buffer, reconstructing any implicit levels of indirection used in the representation of the type. It also properly initializes any type tags that appear within the value, presuming that the buffer was written by a different program and that tag values for the"same" type might vary from one executable to another. 1.a

Static Semantics

The generic library package Storage_IO has the following declaration: 2

```
{AI12-0302-1} with Ada.IO_Exceptions;                                           3/5
with System.Storage_Elements;
generic
   type Element_Type is private;
package Ada.Storage_IO
   with Preelaborate, Global => in out synchronized is

   Buffer_Size : constant System.Storage_Elements.Storage_Count :=              4
      implementation-defined;
   subtype Buffer_Type is
      System.Storage_Elements.Storage_Array(1..Buffer_Size);

   -- Input and output operations                                              5

   procedure Read (Buffer : in  Buffer_Type; Item : out Element_Type);          6
```

```
7          procedure Write(Buffer : out Buffer_Type; Item : in  Element_Type);
8          -- Exceptions
9          Data_Error   : exception renames IO_Exceptions.Data_Error;
       end Ada.Storage_IO;
```

10 In each instance, the constant Buffer_Size has a value that is the size (in storage elements) of the buffer required to represent the content of an object of subtype Element_Type, including any implicit levels of indirection used by the implementation. The Read and Write procedures of Storage_IO correspond to the Read and Write procedures of Direct_IO (see A.8.4), but with the content of the Item parameter being read from or written into the specified Buffer, rather than an external file.

10.a **Reason:** As with Direct_IO, the Element_Type formal of Storage_IO does not have an unknown_discriminant_part so that there is a well-defined upper bound on the size of the buffer needed to hold the content of an object of the formal subtype (i.e. Buffer_Size). If there are no implicit levels of indirection, Buffer_Size will typically equal:

10.b `(Element_Type'Size + System.Storage_Unit - 1) / System.Storage_Unit`

10.c **Implementation defined:** The value of Buffer_Size in Storage_IO.

11 NOTE A buffer used for Storage_IO holds only one element at a time; an external file used for Direct_IO holds a sequence of elements.

Extensions to Ada 83

11.a/3 {*AI05-0005-1*} Storage_IO is new in Ada 95.

A.10 Text Input-Output

Static Semantics

1/5 {*AI05-0299-1*} {*AI12-0449-1*} This subclause describes the package Text_IO, which provides facilities for input and output in human-readable form. Each file is read or written sequentially, as a sequence of characters grouped into lines, and as a sequence of lines grouped into pages. The specification of the package is given below in A.10.1.

2/5 {*AI05-0299-1*} {*AI12-0449-1*} The facilities for file management given above, in A.8.2 and A.8.3, are available for text input-output. In place of Read and Write, however, there are procedures Get and Put that input values of suitable types from text files, and output values to them. These values are provided to the Put procedures, and returned by the Get procedures, in a parameter Item. Several overloaded procedures of these names exist, for different types of Item. These Get procedures analyze the input sequences of characters based on lexical elements (see Clause 2) and return the corresponding values; the Put procedures output the given values as appropriate lexical elements. Procedures Get and Put are also available that input and output individual characters treated as character values rather than as lexical elements. Related to character input are procedures to look ahead at the next character without reading it, and to read a character "immediately" without waiting for an end-of-line to signal availability.

3 In addition to the procedures Get and Put for numeric and enumeration types of Item that operate on text files, analogous procedures are provided that read from and write to a parameter of type String. These procedures perform the same analysis and composition of character sequences as their counterparts which have a file parameter.

4 For all Get and Put procedures that operate on text files, and for many other subprograms, there are forms with and without a file parameter. Each such Get procedure operates on an input file, and each such Put procedure operates on an output file. If no file is specified, a default input file or a default output file is used.

5 At the beginning of program execution the default input and output files are the so-called standard input file and standard output file. These files are open, have respectively the current modes In_File and

Out_File, and are associated with two implementation-defined external files. Procedures are provided to change the current default input file and the current default output file.

Implementation defined: The external files associated with the standard input, standard output, and standard error files. 5.a/2

Implementation Note: {*8652/0113*} {*AI95-00087-01*} The default input file and default output file are not the names of distinct file objects, but rather the *role* played by one or more (other) file object(s). Thus, they generally will be implemented as accesses to another file object. An implementation that implements them by copying them is incorrect. 5.a.1/1

At the beginning of program execution a default file for program-dependent error-related text output is the so-called standard error file. This file is open, has the current mode Out_File, and is associated with an implementation-defined external file. A procedure is provided to change the current default error file. 6

From a logical point of view, a text file is a sequence of pages, a page is a sequence of lines, and a line is a sequence of characters; the end of a line is marked by a *line terminator*; the end of a page is marked by the combination of a line terminator immediately followed by a *page terminator*; and the end of a file is marked by the combination of a line terminator immediately followed by a page terminator and then a *file terminator*. Terminators are generated during output; either by calls of procedures provided expressly for that purpose; or implicitly as part of other operations, for example, when a bounded line length, a bounded page length, or both, have been specified for a file. 7

{*AI12-0444-1*} The actual nature of terminators is not defined by the language and hence depends on the implementation. Although terminators are recognized or generated by certain of the procedures that follow, they are not necessarily implemented as characters or as sequences of characters. Whether they are characters (and if so which ones) in any particular implementation is not of concern to a user who neither explicitly outputs nor explicitly inputs control characters. The effect of input (Get) or output (Put) of control characters (other than horizontal tabulation) is not specified by the language. 8/5

The characters of a line are numbered, starting from one; the number of a character is called its *column number*. For a line terminator, a column number is also defined: it is one more than the number of characters in the line. The lines of a page, and the pages of a file, are similarly numbered. The current column number is the column number of the next character or line terminator to be transferred. The current line number is the number of the current line. The current page number is the number of the current page. These numbers are values of the subtype Positive_Count of the type Count (by convention, the value zero of the type Count is used to indicate special conditions). 9

```
type Count is range 0 .. implementation-defined;
subtype Positive_Count is Count range 1 .. Count'Last;
```
10

For an output file or an append file, a *maximum line length* can be specified and a *maximum page length* can be specified. If a value to be output cannot fit on the current line, for a specified maximum line length, then a new line is automatically started before the value is output; if, further, this new line cannot fit on the current page, for a specified maximum page length, then a new page is automatically started before the value is output. Functions are provided to determine the maximum line length and the maximum page length. When a file is opened with mode Out_File or Append_File, both values are zero: by convention, this means that the line lengths and page lengths are unbounded. (Consequently, output consists of a single line if the subprograms for explicit control of line and page structure are not used.) The constant Unbounded is provided for this purpose. 11

Extensions to Ada 83

Append_File is new in Ada 95. 11.a

A.10.1 The Package Text_IO

Static Semantics

1 The library package Text_IO has the following declaration:

2/5
```
{AI12-0302-1} with Ada.IO_Exceptions;
package Ada.Text_IO
   with Global => in out synchronized is
```

3
```
   type File_Type is limited private;
```

4
```
   type File_Mode is (In_File, Out_File, Append_File);
```

5
```
   type Count is range 0 .. implementation-defined;
   subtype Positive_Count is Count range 1 .. Count'Last;
   Unbounded : constant Count := 0; -- line and page length
```

6
```
   subtype Field       is Integer range 0 .. implementation-defined;
   subtype Number_Base is Integer range 2 .. 16;
```

7
```
   type Type_Set is (Lower_Case, Upper_Case);
```

8
```
   -- File Management
```

9

                        Form : in Wide_String := "");
      function Name    (File : in File_Type) return Wide_String;
      function Form    (File : in File_Type) return Wide_String;
   end Wide_File_Names;
```

{*AI12-0021-1*}

```
   package Wide_Wide_File_Names is
      -- File management
      procedure Create (File : in out File_Type;
                        Mode : in File_Mode := Out_File;
                        Name : in Wide_Wide_String := "";
                        Form : in Wide_Wide_String := "");
      procedure Open   (File : in out File_Type;
                        Mode : in File_Mode;
                        Name : in Wide_Wide_String;
                        Form : in Wide_Wide_String := "");
      function Name    (File : in File_Type) return Wide_Wide_String;
      function Form    (File : in File_Type) return Wide_Wide_String;
   end Wide_Wide_File_Names;
private
   ... -- not specified by the language
end Ada.Text_IO;
```

{*AI95-00360-01*} The type File_Type needs finalization (see 7.6).

Incompatibilities With Ada 83

Append_File is a new element of enumeration type File_Mode.

Extensions to Ada 83

Get_Immediate, Look_Ahead, the subprograms for dealing with standard error, the type File_Access and its associated subprograms, and the generic packages Modular_IO and Decimal_IO are new in Ada 95.

Incompatibilities With Ada 95

{*AI95-00360-01*} **Amendment Correction:** Text_IO.File_Type is defined to need finalization. If the restriction No_Nested_Finalization (see D.7) applies to the partition, and File_Type does not have a controlled part, it will not be allowed in local objects in Ada 2005 whereas it would be allowed in original Ada 95. Such code is not portable, as another Ada compiler may have a controlled part in File_Type, and thus would be illegal.

Wording Changes from Ada 95

{*8652/0051*} {*AI95-00057-01*} **Corrigendum:** Corrected the parameter mode of Flush; otherwise it could not be used on Standard_Output. 86.d/2

{*AI95-00301-01*} The Text_IO.Get_Line functions are new; they are described in A.10.7, “Input-Output of Characters and Strings”. 86.e/2

Incompatibilities With Ada 2012

{*AI12-0021-1*} The Wide_File_Names and Wide_Wide_File_Names nested packages are newly added to Ada.Text_IO. Therefore, a use clause conflict is possible; see the introduction of Annex A for more on this topic. 86.f/5

A.10.2 Text File Management

Static Semantics

{*AI12-0449-1*} The only allowed file modes for text files are the modes In_File, Out_File, and Append_File. The subprograms given in A.8.2 for the control of external files, and the function End_Of_File given in A.8.3 for sequential input-output, are also available for text files. There is also a version of End_Of_File that refers to the current default input file. For text files, the procedures have the following additional effects: 1/5

- For the procedures Create and Open: After a file with mode Out_File or Append_File is opened, the page length and line length are unbounded (both have the conventional value zero). After a file (of any mode) is opened, the current column, current line, and current page numbers are set to one. If the mode is Append_File, it is implementation defined whether a page terminator will separate preexisting text in the file from the new text to be written. 2

  Reason: For a file with mode Append_File, although it may seem more sensible for Open to set the current column, line, and page number based on the number of pages in the file, the number of lines on the last page, and the number of columns in the last line, we rejected this approach because of implementation costs; it would require the implementation to scan the file before doing the append, or to do processing that would be equivalent in effect. 2.a

  For similar reasons, there is no requirement to erase the last page terminator of the file, nor to insert an explicit page terminator in the case when the final page terminator of a file is represented implicitly by the implementation. 2.b

- For the procedure Close: If the file has the current mode Out_File or Append_File, has the effect of calling New_Page, unless the current page is already terminated; then outputs a file terminator. 3

- For the procedure Reset: If the file has the current mode Out_File or Append_File, has the effect of calling New_Page, unless the current page is already terminated; then outputs a file terminator. The current column, line, and page numbers are set to one, and the line and page lengths to Unbounded. If the new mode is Append_File, it is implementation defined whether a page terminator will separate preexisting text in the file from the new text to be written. 4

  Reason: The behavior of Reset should be similar to closing a file and reopening it with the given mode 4.a

The exception Mode_Error is propagated by the procedure Reset upon an attempt to change the mode of a file that is the current default input file, the current default output file, or the current default error file. 5

NOTE An implementation can define the Form parameter of Create and Open to control effects including the following: 6

- the interpretation of line and column numbers for an interactive file, and 7
- the interpretation of text formats in a file created by a foreign program. 8

A.10.3 Default Input, Output, and Error Files

Static Semantics

The following subprograms provide for the control of the particular default files that are used when a file parameter is omitted from a Get, Put, or other operation of text input-output described below, or when application-dependent error-related text is to be output. 1

2 `procedure Set_Input(File : in File_Type);`

3 Operates on a file of mode In_File. Sets the current default input file to File.

4 The exception Status_Error is propagated if the given file is not open. The exception Mode_Error is propagated if the mode of the given file is not In_File.

5 `procedure Set_Output(File : in File_Type);`
`procedure Set_Error (File : in File_Type);`

6 Each operates on a file of mode Out_File or Append_File. Set_Output sets the current default output file to File. Set_Error sets the current default error file to File. The exception Status_Error is propagated if the given file is not open. The exception Mode_Error is propagated if the mode of the given file is not Out_File or Append_File.

7 `function Standard_Input return File_Type;`
`function Standard_Input return File_Access;`

8 Returns the standard input file (see A.10), or an access value designating the standard input file, respectively.

9 `function Standard_Output return File_Type;`
`function Standard_Output return File_Access;`

10 Returns the standard output file (see A.10) or an access value designating the standard output file, respectively.

11 `function Standard_Error return File_Type;`
`function Standard_Error return File_Access;`

12/1 {*8652/0052*} {*AI95-00194-01*} Returns the standard error file (see A.10), or an access value designating the standard error file, respectively.

13 The Form strings implicitly associated with the opening of Standard_Input, Standard_Output, and Standard_Error at the start of program execution are implementation defined.

14 `function Current_Input return File_Type;`
`function Current_Input return File_Access;`

15 Returns the current default input file, or an access value designating the current default input file, respectively.

16 `function Current_Output return File_Type;`
`function Current_Output return File_Access;`

17 Returns the current default output file, or an access value designating the current default output file, respectively.

18 `function Current_Error return File_Type;`
`function Current_Error return File_Access;`

19 Returns the current default error file, or an access value designating the current default error file, respectively.

20/1 {*8652/0051*} {*AI95-00057-01*} `procedure Flush (File : in File_Type);`
`procedure Flush;`

21/4 {*AI12-0130-1*} [The effect of Flush is the same as the corresponding subprogram in Sequential_IO (see A.8.2).] If File is not explicitly specified, Current_Output is used.

21.a/4 **Discussion:** {*AI12-0052-1*} For the purpose of determining whether concurrent calls on text input-output subprograms are required to perform as specified, subprograms that implicitly operate on one of the default input-output files are considered to have a parameter of Current_Input or Current_Output (as appropriate). The result of Current_Output is considered to be overlapping with the file given to the latest call of Set_Output (or Standard_Output if Set_Output

hasn't been called); a corresponding consideration applies to the result of Current_Input. See the introduction of Annex A for details.

Erroneous Execution

{*8652/0053*} {*AI95-00063-01*} The execution of a program is erroneous if it invokes an operation on a current default input, default output, or default error file, and if the corresponding file object is closed or no longer exists. 22/1

Ramification: {*8652/0053*} {*AI95-00063-01*} Closing a default file, then setting the default file to another open file before accessing it is not erroneous. 22.a.1/1

This paragraph was deleted.{*8652/0053*} {*AI95-00063-01*} 23/1

NOTE 1 The standard input, standard output, and standard error files cannot be opened, closed, reset, or deleted, because the parameter File of the corresponding procedures has the mode **in out**. 24

NOTE 2 The standard input, standard output, and standard error files are different file objects, but not necessarily different external files. 25

Wording Changes from Ada 95

{*8652/0051*} {*AI95-00057-01*} **Corrigendum:** Corrected the parameter mode of Flush; otherwise it could not be used on Standard_Output. 25.a/2

{*8652/0052*} {*AI95-00194-01*} **Corrigendum:** Corrected Standard_Error so it refers to the correct file. 25.b/2

{*8652/0053*} {*AI95-00063-01*} **Corrigendum:** Clarified that execution is erroneous only when a closed default file is accessed. 25.c/2

Wording Changes from Ada 2012

{*AI12-0130-1*} **Corrigendum:** Moved the definition of Flush to A.8.2, as all input-output packages now have it. 25.d/4

A.10.4 Specification of Line and Page Lengths

Static Semantics

{*AI12-0445-1*} The subprograms described in this subclause are concerned with the line and page structure of a file of mode Out_File or Append_File. They operate either on the file given as the first parameter, or, in the absence of such a file parameter, on the current default output file. They provide for output of text with a specified maximum line length or page length. In these cases, line and page terminators are output implicitly and automatically when necessary. When line and page lengths are unbounded (that is, when they have the conventional value zero), as in the case of a newly opened file, new lines and new pages are only started when explicitly called for. 1/5

In all cases, the exception Status_Error is propagated if the file to be used is not open; the exception Mode_Error is propagated if the mode of the file is not Out_File or Append_File. 2

```
procedure Set_Line_Length(File : in File_Type; To : in Count);
procedure Set_Line_Length(To   : in Count);
```
3

Sets the maximum line length of the specified output or append file to the number of characters specified by To. The value zero for To specifies an unbounded line length. 4

Ramification: The setting does not affect the lengths of lines in the existing file, rather it only influences subsequent output operations. 4.a

The exception Use_Error is propagated if the specified line length is inappropriate for the associated external file. 5

6
```
procedure Set_Page_Length(File : in File_Type; To : in Count);
procedure Set_Page_Length(To   : in Count);
```

7 Sets the maximum page length of the specified output or append file to the number of lines specified by To. The value zero for To specifies an unbounded page length.

8 The exception Use_Error is propagated if the specified page length is inappropriate for the associated external file.

9
```
function Line_Length(File : in File_Type) return Count;
function Line_Length return Count;
```

10 Returns the maximum line length currently set for the specified output or append file, or zero if the line length is unbounded.

11
```
function Page_Length(File : in File_Type) return Count;
function Page_Length return Count;
```

12 Returns the maximum page length currently set for the specified output or append file, or zero if the page length is unbounded.

A.10.5 Operations on Columns, Lines, and Pages

Static Semantics

1 The subprograms described in this subclause provide for explicit control of line and page structure; they operate either on the file given as the first parameter, or, in the absence of such a file parameter, on the appropriate (input or output) current default file. The exception Status_Error is propagated by any of these subprograms if the file to be used is not open.

2
```
procedure New_Line(File : in File_Type; Spacing : in Positive_Count := 1);
procedure New_Line(Spacing : in Positive_Count := 1);
```

3 Operates on a file of mode Out_File or Append_File.

4 For a Spacing of one: Outputs a line terminator and sets the current column number to one. Then increments the current line number by one, except in the case that the current line number is already greater than or equal to the maximum page length, for a bounded page length; in that case a page terminator is output, the current page number is incremented by one, and the current line number is set to one.

5 For a Spacing greater than one, the above actions are performed Spacing times.

6 The exception Mode_Error is propagated if the mode is not Out_File or Append_File.

7
```
procedure Skip_Line(File  : in File_Type; Spacing : in Positive_Count := 1);
procedure Skip_Line(Spacing : in Positive_Count := 1);
```

8 Operates on a file of mode In_File.

9 For a Spacing of one: Reads and discards all characters until a line terminator has been read, and then sets the current column number to one. If the line terminator is not immediately followed by a page terminator, the current line number is incremented by one. Otherwise, if the line terminator is immediately followed by a page terminator, then the page terminator is skipped, the current page number is incremented by one, and the current line number is set to one.

10 For a Spacing greater than one, the above actions are performed Spacing times.

11 The exception Mode_Error is propagated if the mode is not In_File. The exception End_Error is propagated if an attempt is made to read a file terminator.

```
function End_Of_Line(File : in File_Type) return Boolean;
function End_Of_Line return Boolean;
```

{*AI05-0264-1*} Operates on a file of mode In_File. Returns True if a line terminator or a file terminator is next; otherwise, returns False. 13/3

The exception Mode_Error is propagated if the mode is not In_File. 14

```
procedure New_Page(File : in File_Type);
procedure New_Page;
```

Operates on a file of mode Out_File or Append_File. Outputs a line terminator if the current line is not terminated, or if the current page is empty (that is, if the current column and line numbers are both equal to one). Then outputs a page terminator, which terminates the current page. Adds one to the current page number and sets the current column and line numbers to one. 16

The exception Mode_Error is propagated if the mode is not Out_File or Append_File. 17

```
procedure Skip_Page(File : in File_Type);
procedure Skip_Page;
```

Operates on a file of mode In_File. Reads and discards all characters and line terminators until a page terminator has been read. Then adds one to the current page number, and sets the current column and line numbers to one. 19

The exception Mode_Error is propagated if the mode is not In_File. The exception End_Error is propagated if an attempt is made to read a file terminator. 20

```
function End_Of_Page(File : in File_Type) return Boolean;
function End_Of_Page return Boolean;
```

{*AI05-0264-1*} Operates on a file of mode In_File. Returns True if the combination of a line terminator and a page terminator is next, or if a file terminator is next; otherwise, returns False. 22/3

The exception Mode_Error is propagated if the mode is not In_File. 23

```
function End_Of_File(File : in File_Type) return Boolean;
function End_Of_File return Boolean;
```

{*AI05-0264-1*} Operates on a file of mode In_File. Returns True if a file terminator is next, or if the combination of a line, a page, and a file terminator is next; otherwise, returns False. 25/3

The exception Mode_Error is propagated if the mode is not In_File. 26

The following subprograms provide for the control of the current position of reading or writing in a file. In all cases, the default file is the current output file. 27

```
procedure Set_Col(File : in File_Type; To : in Positive_Count);
procedure Set_Col(To   : in Positive_Count);
```

If the file mode is Out_File or Append_File: 29

- If the value specified by To is greater than the current column number, outputs spaces, adding one to the current column number after each space, until the current column number equals the specified value. If the value specified by To is equal to the current column number, there is no effect. If the value specified by To is less than the current column number, has the effect of calling New_Line (with a spacing of one), then outputs (To – 1) spaces, and sets the current column number to the specified value. 30
- The exception Layout_Error is propagated if the value specified by To exceeds Line_Length when the line length is bounded (that is, when it does not have the conventional value zero). 31

If the file mode is In_File: 32

- Reads (and discards) individual characters, line terminators, and page terminators, until the next character to be read has a column number that equals the value specified by To; there is no effect if the current column number already equals this value. Each transfer of a character or terminator maintains the current column, line, and page numbers in the same way as a Get procedure (see A.10.6). (Short lines will be skipped until a line is reached that has a character at the specified column position.)

- The exception End_Error is propagated if an attempt is made to read a file terminator.

```
procedure Set_Line(File : in File_Type; To : in Positive_Count);
procedure Set_Line(To   : in Positive_Count);
```

If the file mode is Out_File or Append_File:

- {*AI05-0038-1*} If the value specified by To is greater than the current line number, has the effect of repeatedly calling New_Line (with a spacing of one), until the current line number equals the specified value. If the value specified by To is equal to the current line number, there is no effect. If the value specified by To is less than the current line number, has the effect of calling New_Page followed, if To is greater than 1, by a call of New_Line with a spacing equal to (To – 1).

- The exception Layout_Error is propagated if the value specified by To exceeds Page_Length when the page length is bounded (that is, when it does not have the conventional value zero).

If the mode is In_File:

- Has the effect of repeatedly calling Skip_Line (with a spacing of one), until the current line number equals the value specified by To; there is no effect if the current line number already equals this value. (Short pages will be skipped until a page is reached that has a line at the specified line position.)

- The exception End_Error is propagated if an attempt is made to read a file terminator.

```
function Col(File : in File_Type) return Positive_Count;
function Col return Positive_Count;
```

Returns the current column number.

The exception Layout_Error is propagated if this number exceeds Count'Last.

```
function Line(File : in File_Type) return Positive_Count;
function Line return Positive_Count;
```

Returns the current line number.

The exception Layout_Error is propagated if this number exceeds Count'Last.

```
function Page(File : in File_Type) return Positive_Count;
function Page return Positive_Count;
```

Returns the current page number.

The exception Layout_Error is propagated if this number exceeds Count'Last.

The column number, line number, or page number are allowed to exceed Count'Last (as a consequence of the input or output of sufficiently many characters, lines, or pages). These events do not cause any exception to be propagated. However, a call of Col, Line, or Page propagates the exception Layout_Error if the corresponding number exceeds Count'Last.

NOTE {*AI12-0440-1*} A page terminator is always skipped whenever the preceding line terminator is skipped. An implementation can represent the combination of these terminators by a single character, provided that it is properly recognized on input.

Inconsistencies With Ada 2005

{*AI05-0038-1*} **Correction:** Fixed a glitch in Set_Line such that we could have called New_Line(0), which would have to raise Constraint_Error. It's now defined to work. The bug occurred in Ada 95 and Ada 2005. It's very unlikely that any real programs depend on this exception being raised. 52.a/3

A.10.6 Get and Put Procedures

Static Semantics

The procedures Get and Put for items of the type Character, String, numeric types, and enumeration types are described in subsequent subclauses. Features of these procedures that are common to most of these types are described in this subclause. The Get and Put procedures for items of type Character and String deal with individual character values; the Get and Put procedures for numeric and enumeration types treat the items as lexical elements. 1

All procedures Get and Put have forms with a file parameter, written first. Where this parameter is omitted, the appropriate (input or output) current default file is understood to be specified. Each procedure Get operates on a file of mode In_File. Each procedure Put operates on a file of mode Out_File or Append_File. 2

All procedures Get and Put maintain the current column, line, and page numbers of the specified file: the effect of each of these procedures upon these numbers is the result of the effects of individual transfers of characters and of individual output or skipping of terminators. Each transfer of a character adds one to the current column number. Each output of a line terminator sets the current column number to one and adds one to the current line number. Each output of a page terminator sets the current column and line numbers to one and adds one to the current page number. For input, each skipping of a line terminator sets the current column number to one and adds one to the current line number; each skipping of a page terminator sets the current column and line numbers to one and adds one to the current page number. Similar considerations apply to the procedures Get_Line, Put_Line, and Set_Col. 3

Several Get and Put procedures, for numeric and enumeration types, have *format* parameters which specify field lengths; these parameters are of the nonnegative subtype Field of the type Integer. 4

{*AI95-00223-01*} Input-output of enumeration values uses the syntax of the corresponding lexical elements. Any Get procedure for an enumeration type begins by skipping any leading blanks, or line or page terminators. A *blank* is defined as a space or a horizontal tabulation character. Next, characters are input only so long as the sequence input is an initial sequence of an identifier or of a character literal (in particular, input ceases when a line terminator is encountered). The character or line terminator that causes input to cease remains available for subsequent input. 5/2

For a numeric type, the Get procedures have a format parameter called Width. If the value given for this parameter is zero, the Get procedure proceeds in the same manner as for enumeration types, but using the syntax of numeric literals instead of that of enumeration literals. If a nonzero value is given, then exactly Width characters are input, or the characters up to a line terminator, whichever comes first; any skipped leading blanks are included in the count. The syntax used for numeric literals is an extended syntax that allows a leading sign (but no intervening blanks, or line or page terminators) and that also allows (for real types) an integer literal as well as forms that have digits only before the point or only after the point. 6

{*AI12-0445-1*} Any Put procedure, for an item of a numeric or an enumeration type, outputs the value of the item as a numeric literal, identifier, or character literal, as appropriate. This is preceded by leading spaces if required by the format parameters Width or Fore (as described in later subclauses), and then a minus sign for a negative value; for an enumeration type, the spaces follow instead of leading. The format given for a Put procedure is overridden if it is insufficiently wide, by using the minimum necessary width. 7/5

8 Two further cases arise for Put procedures for numeric and enumeration types, if the line length of the specified output file is bounded (that is, if it does not have the conventional value zero). If the number of characters to be output does not exceed the maximum line length, but is such that they cannot fit on the current line, starting from the current column, then (in effect) New_Line is called (with a spacing of one) before output of the item. Otherwise, if the number of characters exceeds the maximum line length, then the exception Layout_Error is propagated and nothing is output.

9 The exception Status_Error is propagated by any of the procedures Get, Get_Line, Put, and Put_Line if the file to be used is not open. The exception Mode_Error is propagated by the procedures Get and Get_Line if the mode of the file to be used is not In_File; and by the procedures Put and Put_Line, if the mode is not Out_File or Append_File.

10 The exception End_Error is propagated by a Get procedure if an attempt is made to skip a file terminator. The exception Data_Error is propagated by a Get procedure if the sequence finally input is not a lexical element corresponding to the type, in particular if no characters were input; for this test, leading blanks are ignored; for an item of a numeric type, when a sign is input, this rule applies to the succeeding numeric literal. The exception Layout_Error is propagated by a Put procedure that outputs to a parameter of type String, if the length of the actual string is insufficient for the output of the item.

Examples

11/5 {*AI12-0449-1*} In the examples, here and in A.10.8 and A.10.9, the string quotes and the lower case letter b are not transferred: they are shown only to reveal the layout and spaces.

12
```
N : Integer;
   ...
Get(N);
```

13
```
--  Characters at input   Sequence input    Value of N

--  bb–12535b             –12535            –12535
--  bb12_535e1b           12_535e1          125350
--  bb12_535e;            12_535e           (none) Data_Error raised
```

14 Example of overridden width parameter:

15
```
Put(Item => -23, Width => 2);  -- "–23"
```

Wording Changes from Ada 95

15.a/2 {*AI95-00223-01*} Removed conflicting text describing the skipping of blanks for a Get procedure.

A.10.7 Input-Output of Characters and Strings

Static Semantics

1 For an item of type Character the following procedures are provided:

2
```
procedure Get(File : in File_Type; Item : out Character);
procedure Get(Item : out Character);
```

3 After skipping any line terminators and any page terminators, reads the next character from the specified input file and returns the value of this character in the out parameter Item.

4 The exception End_Error is propagated if an attempt is made to skip a file terminator.

5
```
procedure Put(File : in File_Type; Item : in Character);
procedure Put(Item : in Character);
```

6 If the line length of the specified output file is bounded (that is, does not have the conventional value zero), and the current column number exceeds it, has the effect of calling New_Line with a spacing of one. Then, or otherwise, outputs the given character to the file.

```
procedure Look_Ahead (File        : in  File_Type;                    7
                      Item        : out Character;
                      End_Of_Line : out Boolean);
procedure Look_Ahead (Item        : out Character;
                      End_Of_Line : out Boolean);
```

{*AI05-0038-1*} {*AI05-0264-1*} Status_Error is propagated if the file is not open. Mode_Error is propagated if the mode of the file is not In_File. Sets End_Of_Line to True if at end of line, including if at end of page or at end of file; in each of these cases the value of Item is not specified. Otherwise, End_Of_Line is set to False and Item is set to the next character (without consuming it) from the file. 8/3

```
procedure Get_Immediate(File : in  File_Type;                         9
                        Item : out Character);
procedure Get_Immediate(Item : out Character);
```

{*AI05-0038-1*} Reads the next character, either control or graphic, from the specified File or the default input file. Status_Error is propagated if the file is not open. Mode_Error is propagated if the mode of the file is not In_File. End_Error is propagated if at the end of the file. The current column, line and page numbers for the file are not affected. 10/3

```
procedure Get_Immediate(File      : in  File_Type;                    11
                        Item      : out Character;
                        Available : out Boolean);
procedure Get_Immediate(Item      : out Character;
                        Available : out Boolean);
```

{*AI05-0038-1*} If a character, either control or graphic, is available from the specified File or the default input file, then the character is read; Available is True and Item contains the value of this character. If a character is not available, then Available is False and the value of Item is not specified. Status_Error is propagated if the file is not open. Mode_Error is propagated if the mode of the file is not In_File. End_Error is propagated if at the end of the file. The current column, line and page numbers for the file are not affected. 12/3

{*AI95-00301-01*} For an item of type String the following subprograms are provided: 13/2

```
procedure Get(File : in File_Type; Item : out String);                14
procedure Get(Item : out String);
```

Determines the length of the given string and attempts that number of Get operations for successive characters of the string (in particular, no operation is performed if the string is null). 15

```
procedure Put(File : in File_Type; Item : in String);                 16
procedure Put(Item : in String);
```

Determines the length of the given string and attempts that number of Put operations for successive characters of the string (in particular, no operation is performed if the string is null). 17

```
function Get_Line(File : in File_Type) return String;                 17.1/2
function Get_Line return String;
```

{*AI95-00301-01*} Returns a result string constructed by reading successive characters from the specified input file, and assigning them to successive characters of the result string. The result string has a lower bound of 1 and an upper bound of the number of characters read. Reading stops when the end of the line is met; Skip_Line is then (in effect) called with a spacing of 1. 17.2/2

{*AI95-00301-01*} Constraint_Error is raised if the length of the line exceeds Positive'Last; in this case, the line number and page number are unchanged, and the column number is unspecified but no less than it was before the call. The exception End_Error is propagated if an attempt is made to skip a file terminator. 17.3/2

17.a/2 **Ramification:** {*AI95-00301-01*} Precisely what is left in the file is unspecified if Constraint_Error is raised because the line doesn't fit in a String; it should be consistent with column number. This allows implementers to use whatever buffering scheme makes sense. But the line terminator is not skipped in this case.

18
```
procedure Get_Line(File : in File_Type;
                   Item : out String;
                   Last : out Natural);
procedure Get_Line(Item : out String;
                   Last : out Natural);
```

19 Reads successive characters from the specified input file and assigns them to successive characters of the specified string. Reading stops if the end of the string is met. Reading also stops if the end of the line is met before meeting the end of the string; in this case Skip_Line is (in effect) called with a spacing of 1. The values of characters not assigned are not specified.

20 If characters are read, returns in Last the index value such that Item(Last) is the last character assigned (the index of the first character assigned is Item'First). If no characters are read, returns in Last an index value that is one less than Item'First. The exception End_Error is propagated if an attempt is made to skip a file terminator.

21
```
procedure Put_Line(File : in File_Type; Item : in String);
procedure Put_Line(Item : in String);
```

22 Calls the procedure Put for the given string, and then the procedure New_Line with a spacing of one.

Implementation Advice

23 The Get_Immediate procedures should be implemented with unbuffered input. For a device such as a keyboard, input should be “available” if a key has already been typed, whereas for a disk file, input should always be available except at end of file. For a file associated with a keyboard-like device, any line-editing features of the underlying operating system should be disabled during the execution of Get_Immediate.

23.a/2 **Implementation Advice:** Get_Immediate should be implemented with unbuffered input; input should be available immediately; line-editing should be disabled.

24 NOTE 1 Get_Immediate can be used to read a single key from the keyboard “immediately”; that is, without waiting for an end of line. In a call of Get_Immediate without the parameter Available, the caller will wait until a character is available.

25 NOTE 2 In a literal string parameter of Put, the enclosing string bracket characters are not output. Each doubled string bracket character in the enclosed string is output as a single string bracket character, as a consequence of the rule for string literals (see 2.6).

26 NOTE 3 A string read by Get or written by Put can extend over several lines. An implementation is allowed to assume that certain external files do not contain page terminators, in which case Get_Line and Skip_Line can return as soon as a line terminator is read.

Incompatibilities With Ada 95

26.a/3 {*AI95-00301-01*} {*AI05-0005-1*} The Get_Line functions are added to Ada.Text_IO. If Ada.Text_IO is referenced in a use_clause, and a function Get_Line is defined in a package that is also referenced in a use_clause, the user-defined Get_Line may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur.

Extensions to Ada 95

26.b/2 {*AI95-00301-01*} The Text_IO.Get_Line functions are new.

Wording Changes from Ada 2005

26.c/3 {*AI05-0038-1*} **Correction:** Added missing wording about raising Status_Error to Look_Ahead and Get_Immediate.

A.10.8 Input-Output for Integer Types

Static Semantics

The following procedures are defined in the generic packages Integer_IO and Modular_IO, which have to be instantiated for the appropriate signed integer or modular type respectively (indicated by Num in the specifications). 1

Values are output as decimal or based literals, without low line characters or exponent, and, for Integer_IO, preceded by a minus sign if negative. The format (which includes any leading spaces and minus sign) can be specified by an optional field width parameter. Values of widths of fields in output formats are of the nonnegative integer subtype Field. Values of bases are of the integer subtype Number_Base. 2

```
subtype Number_Base is Integer range 2 .. 16;
```
3

The default field width and base to be used by output procedures are defined by the following variables that are declared in the generic packages Integer_IO and Modular_IO: 4

```
Default_Width : Field := Num'Width;
Default_Base  : Number_Base := 10;
```
5

The following procedures are provided: 6

```
procedure Get(File : in File_Type; Item : out Num; Width : in Field := 0);
procedure Get(Item : out Num; Width : in Field := 0);
```
7

If the value of the parameter Width is zero, skips any leading blanks, line terminators, or page terminators, then reads a plus sign if present or (for a signed type only) a minus sign if present, then reads the longest possible sequence of characters matching the syntax of a numeric literal without a point. If a nonzero value of Width is supplied, then exactly Width characters are input, or the characters (possibly none) up to a line terminator, whichever comes first; any skipped leading blanks are included in the count. 8

Returns, in the parameter Item, the value of type Num that corresponds to the sequence input. 9

{*AI05-0038-1*} The exception Data_Error is propagated if the sequence of characters read does not form a legal integer literal or if the value obtained is not of the subtype Num. 10/3

```
procedure Put(File  : in File_Type;
              Item  : in Num;
              Width : in Field := Default_Width;
              Base  : in Number_Base := Default_Base);

procedure Put(Item  : in Num;
              Width : in Field := Default_Width;
              Base  : in Number_Base := Default_Base);
```
11

Outputs the value of the parameter Item as an integer literal, with no low lines, no exponent, and no leading zeros (but a single zero for the value zero), and a preceding minus sign for a negative value. 12

If the resulting sequence of characters to be output has fewer than Width characters, then leading spaces are first output to make up the difference. 13

Uses the syntax for decimal literal if the parameter Base has the value ten (either explicitly or through Default_Base); otherwise, uses the syntax for based literal, with any letters in upper case. 14

15 `procedure Get(From : in String; Item : out Num; Last : out Positive);`

16 Reads an integer value from the beginning of the given string, following the same rules as the Get procedure that reads an integer value from a file, but treating the end of the string as a file terminator. Returns, in the parameter Item, the value of type Num that corresponds to the sequence input. Returns in Last the index value such that From(Last) is the last character read.

17 The exception Data_Error is propagated if the sequence input does not have the required syntax or if the value obtained is not of the subtype Num.

18
```
procedure Put(To   : out String;
              Item : in Num;
              Base : in Number_Base := Default_Base);
```

19 Outputs the value of the parameter Item to the given string, following the same rule as for output to a file, using the length of the given string as the value for Width.

20 Integer_Text_IO is a library package that is a nongeneric equivalent to Text_IO.Integer_IO for the predefined type Integer:

21
```
with Ada.Text_IO;
package Ada.Integer_Text_IO is new Ada.Text_IO.Integer_IO(Integer);
```

22 For each predefined signed integer type, a nongeneric equivalent to Text_IO.Integer_IO is provided, with names such as Ada.Long_Integer_Text_IO.

Implementation Permissions

23/5 {*AI12-0444-1*} The nongeneric equivalent packages can be actual instantiations of the generic package for the appropriate predefined type, though that is not required.

24/3 *This paragraph was deleted.*{*AI05-0038-1*}

Examples

{*AI12-0429-1*} *Examples of use of an instantiation of Text_IO.Integer_IO:*

25/3
```
{AI05-0298-1} subtype Byte_Int is Integer range -127 .. 127;
package Int_IO is new Integer_IO(Byte_Int); use Int_IO;
-- default format used at instantiation,
-- Default_Width = 4, Default_Base = 10
```

26
```
Put(126);                              -- "b126"
Put(-126, 7);                          -- "bbb–126"
Put(126, Width => 13, Base => 2);      -- "bbb2#1111110#"
```

Inconsistencies With Ada 2005

26.a/3 {*AI05-0038-1*} **Correction:** Changed wording to make Integer_IO and Modular_IO raise Data_Error in the same way when the bounds of the subtype are exceeded. There is no value to different behavior, and all surveyed compilers already treat integer and modular values the same way. This could only cause a problem if a program was compiled with some unsurveyed compiler, and the Ada 95-defined behavior is expected for Modular_IO. But note that such code is not portable anyway, as most widely used compilers behave consistently with the new wording, so it is unlikely that such code exists.

A.10.9 Input-Output for Real Types

Static Semantics

1 The following procedures are defined in the generic packages Float_IO, Fixed_IO, and Decimal_IO, which have to be instantiated for the appropriate floating point, ordinary fixed point, or decimal fixed point type respectively (indicated by Num in the specifications).

Values are output as decimal literals without low line characters. The format of each value output consists of a Fore field, a decimal point, an Aft field, and (if a nonzero Exp parameter is supplied) the letter E and an Exp field. The two possible formats thus correspond to: 2

```
Fore  .  Aft
```
3

and to: 4

```
Fore  .  Aft  E  Exp
```
5

without any spaces between these fields. The Fore field may include leading spaces, and a minus sign for negative values. The Aft field includes only decimal digits (possibly with trailing zeros). The Exp field includes the sign (plus or minus) and the exponent (possibly with leading zeros). 6

For floating point types, the default lengths of these fields are defined by the following variables that are declared in the generic package Float_IO: 7

```
Default_Fore : Field := 2;
Default_Aft  : Field := Num'Digits-1;
Default_Exp  : Field := 3;
```
8

For ordinary or decimal fixed point types, the default lengths of these fields are defined by the following variables that are declared in the generic packages Fixed_IO and Decimal_IO, respectively: 9

```
Default_Fore : Field := Num'Fore;
Default_Aft  : Field := Num'Aft;
Default_Exp  : Field := 0;
```
10

The following procedures are provided: 11

```
procedure Get(File : in File_Type; Item : out Num; Width : in Field := 0);
procedure Get(Item : out Num; Width : in Field := 0);
```
12

If the value of the parameter Width is zero, skips any leading blanks, line terminators, or page terminators, then reads the longest possible sequence of characters matching the syntax of any of the following (see 2.4): 13

- [+|–]numeric_literal 14
- [+|–]numeral.[exponent] 15
- [+|–].numeral[exponent] 16
- [+|–]base#based_numeral.#[exponent] 17
- [+|–]base#.based_numeral#[exponent] 18

If a nonzero value of Width is supplied, then exactly Width characters are input, or the characters (possibly none) up to a line terminator, whichever comes first; any skipped leading blanks are included in the count. 19

Returns in the parameter Item the value of type Num that corresponds to the sequence input, preserving the sign (positive if none has been specified) of a zero value if Num is a floating point type and Num'Signed_Zeros is True. 20

The exception Data_Error is propagated if the sequence input does not have the required syntax or if the value obtained is not of the subtype Num. 21

22
```
procedure Put(File : in File_Type;
              Item : in Num;
              Fore : in Field := Default_Fore;
              Aft  : in Field := Default_Aft;
              Exp  : in Field := Default_Exp);

procedure Put(Item : in Num;
              Fore : in Field := Default_Fore;
              Aft  : in Field := Default_Aft;
              Exp  : in Field := Default_Exp);
```

23 Outputs the value of the parameter Item as a decimal literal with the format defined by Fore, Aft and Exp. If the value is negative, or if Num is a floating point type where Num'Signed_Zeros is True and the value is a negatively signed zero, then a minus sign is included in the integer part. If Exp has the value zero, then the integer part to be output has as many digits as are needed to represent the integer part of the value of Item, overriding Fore if necessary, or consists of the digit zero if the value of Item has no integer part.

24 If Exp has a value greater than zero, then the integer part to be output has a single digit, which is nonzero except for the value 0.0 of Item.

25 In both cases, however, if the integer part to be output has fewer than Fore characters, including any minus sign, then leading spaces are first output to make up the difference. The number of digits of the fractional part is given by Aft, or is one if Aft equals zero. The value is rounded; a value of exactly one half in the last place is rounded away from zero.

26 If Exp has the value zero, there is no exponent part. If Exp has a value greater than zero, then the exponent part to be output has as many digits as are needed to represent the exponent part of the value of Item (for which a single digit integer part is used), and includes an initial sign (plus or minus). If the exponent part to be output has fewer than Exp characters, including the sign, then leading zeros precede the digits, to make up the difference. For the value 0.0 of Item, the exponent has the value zero.

27
```
procedure Get(From : in String; Item : out Num; Last : out Positive);
```

28 Reads a real value from the beginning of the given string, following the same rule as the Get procedure that reads a real value from a file, but treating the end of the string as a file terminator. Returns, in the parameter Item, the value of type Num that corresponds to the sequence input. Returns in Last the index value such that From(Last) is the last character read.

29 The exception Data_Error is propagated if the sequence input does not have the required syntax, or if the value obtained is not of the subtype Num.

30
```
procedure Put(To   : out String;
              Item : in Num;
              Aft  : in Field := Default_Aft;
              Exp  : in Field := Default_Exp);
```

31 Outputs the value of the parameter Item to the given string, following the same rule as for output to a file, using a value for Fore such that the sequence of characters output exactly fills the string, including any leading spaces.

32 Float_Text_IO is a library package that is a nongeneric equivalent to Text_IO.Float_IO for the predefined type Float:

33
```
with Ada.Text_IO;
package Ada.Float_Text_IO is new Ada.Text_IO.Float_IO(Float);
```

34 For each predefined floating point type, a nongeneric equivalent to Text_IO.Float_IO is provided, with names such as Ada.Long_Float_Text_IO.

Implementation Permissions

An implementation may extend Get [and Put] for floating point types to support special values such as infinities and NaNs. 35

Discussion: {*AI05-0005-1*} See also the similar permission for the Wide_Wide_Value, Wide_Value, and Value attributes in 3.5. 35.a/3

{*AI12-0444-1*} The implementation of Put may produce an output value with no greater accuracy than that which is supported for the base subtype. The additional accuracy, if any, of the value produced by Put when the number of requested digits in the integer and fractional parts exceeds the required accuracy is implementation defined. 36/5

Discussion: The required accuracy is thus Num'Base'Digits digits if Num is a floating point subtype. For a fixed point subtype the required accuracy is a function of the subtype's Fore, Aft, and Delta attributes. 36.a

Implementation defined: The accuracy of the value produced by Put. 36.b

{*AI12-0444-1*} The nongeneric equivalent packages can be actual instantiations of the generic package for the appropriate predefined type, though that is not required. 37/5

NOTE 1 For an item with a positive value, if output to a string exactly fills the string without leading spaces, then output of the corresponding negative value will propagate Layout_Error. 38

NOTE 2 The rules for the Value attribute (see 3.5) and the rules for Get are based on the same set of formats. 39

Examples

{*AI12-0429-1*} *Examples of use of an instantiation of Text_IO.Float_IO:* 40/5

```
package Real_IO is new Float_IO(Real); use Real_IO;                    41
-- default format used at instantiation, Default_Exp = 3

X : Real := -123.4567;  -- digits 8    (see 3.5.7)                     42

Put(X);   -- default format                          "–1.2345670E+02"  43
Put(X, Fore => 5, Aft => 3, Exp => 2);    -- "bbb–1.235E+2"
Put(X, 5, 3, 0);                                     -- "b–123.457"
```

A.10.10 Input-Output for Enumeration Types

Static Semantics

The following procedures are defined in the generic package Enumeration_IO, which has to be instantiated for the appropriate enumeration type (indicated by Enum in the specification). 1

Values are output using either upper or lower case letters for identifiers. This is specified by the parameter Set, which is of the enumeration type Type_Set. 2

```
type Type_Set is (Lower_Case, Upper_Case);                             3
```

The format (which includes any trailing spaces) can be specified by an optional field width parameter. The default field width and letter case are defined by the following variables that are declared in the generic package Enumeration_IO: 4

```
Default_Width   : Field := 0;                                          5
Default_Setting : Type_Set := Upper_Case;
```

The following procedures are provided: 6

```
procedure Get(File : in File_Type; Item : out Enum);                   7
procedure Get(Item : out Enum);
```

After skipping any leading blanks, line terminators, or page terminators, reads an identifier according to the syntax of this lexical element (lower and upper case being considered equivalent), or a character literal according to the syntax of this lexical element (including the 8

apostrophes). Returns, in the parameter Item, the value of type Enum that corresponds to the sequence input.

9 The exception Data_Error is propagated if the sequence input does not have the required syntax, or if the identifier or character literal does not correspond to a value of the subtype Enum.

10
```
procedure Put(File  : in File_Type;
              Item  : in Enum;
              Width : in Field := Default_Width;
              Set   : in Type_Set := Default_Setting);

procedure Put(Item  : in Enum;
              Width : in Field := Default_Width;
              Set   : in Type_Set := Default_Setting);
```

11 Outputs the value of the parameter Item as an enumeration literal (either an identifier or a character literal). The optional parameter Set indicates whether lower case or upper case is used for identifiers; it has no effect for character literals. If the sequence of characters produced has fewer than Width characters, then trailing spaces are finally output to make up the difference. If Enum is a character type, the sequence of characters produced is as for Enum'Image(Item), as modified by the Width and Set parameters.

11.a/3 **Discussion:** {*AI05-0005-1*} For a character type, the literal might be a Wide_Wide_Character, Wide_Character, or a control character. Whatever Image does for these things is appropriate here, too.

11.b/3 {*AI05-0036-1*} The "characters produced" defines the "characters to be output" in the sense of A.10.6, so a result that cannot fit on any bounded line will raise Layout_Error.

12
```
procedure Get(From : in String; Item : out Enum; Last : out Positive);
```

13 Reads an enumeration value from the beginning of the given string, following the same rule as the Get procedure that reads an enumeration value from a file, but treating the end of the string as a file terminator. Returns, in the parameter Item, the value of type Enum that corresponds to the sequence input. Returns in Last the index value such that From(Last) is the last character read.

14 The exception Data_Error is propagated if the sequence input does not have the required syntax, or if the identifier or character literal does not correspond to a value of the subtype Enum.

14.a/3 **To be honest:** {*AI05-0005-1*} For a character type, it is permissible for the implementation to make Get do the inverse of what Put does, in the case of wide and wide_wide character_literals and control characters.

15
```
procedure Put(To   : out String;
              Item : in Enum;
              Set  : in Type_Set := Default_Setting);
```

16 Outputs the value of the parameter Item to the given string, following the same rule as for output to a file, using the length of the given string as the value for Width.

17/1 {*8652/0054*} {*AI95-00007-01*} Although the specification of the generic package Enumeration_IO would allow instantiation for an integer type, this is not the intended purpose of this generic package, and the effect of such instantiations is not defined by the language.

18 NOTE 1 There is a difference between Put defined for characters, and for enumeration values. Thus

19
```
Ada.Text_IO.Put('A');  -- outputs the character A
```

20
```
package Char_IO is new Ada.Text_IO.Enumeration_IO(Character);
Char_IO.Put('A');  -- outputs the character 'A', between apostrophes
```

21 NOTE 2 The type Boolean is an enumeration type, hence Enumeration_IO can be instantiated for this type.

Wording Changes from Ada 95

21.a/2 {*8652/0054*} {*AI95-00007-01*} **Corrigendum:** Corrected the wording to say Enumeration_IO can be instantiated with an integer type, not a float type.

A.10.11 Input-Output for Bounded Strings

{*AI95-00428-01*} The package Text_IO.Bounded_IO provides input-output in human-readable form for Bounded_Strings. 1/2

Static Semantics

{*AI95-00428-01*} The generic library package Text_IO.Bounded_IO has the following declaration: 2/2

```
{AI12-0302-1} with Ada.Strings.Bounded;                                    3/5
generic
   with package Bounded is
                     new Ada.Strings.Bounded.Generic_Bounded_Length (<>);
package Ada.Text_IO.Bounded_IO
   with Global => in out synchronized is

   procedure Put                                                           4/2
      (File : in File_Type;
       Item : in Bounded.Bounded_String);

   procedure Put                                                           5/2
      (Item : in Bounded.Bounded_String);

   procedure Put_Line                                                      6/2
      (File : in File_Type;
       Item : in Bounded.Bounded_String);

   procedure Put_Line                                                      7/2
      (Item : in Bounded.Bounded_String);

   function Get_Line                                                       8/2
      (File : in File_Type)
      return Bounded.Bounded_String;

   function Get_Line                                                       9/2
      return Bounded.Bounded_String;

   procedure Get_Line                                                      10/2

Extensions to Ada 95

29.a/2 {*AI95-00428-01*} Package Text_IO.Bounded_IO is new.

A.10.12 Input-Output for Unbounded Strings

1/2 {*AI95-00301-01*} The package Text_IO.Unbounded_IO provides input-output in human-readable form for Unbounded_Strings.

Static Semantics

2/2 {*AI95-00301-01*} The library package Text_IO.Unbounded_IO has the following declaration:

3/5
```
{AI12-0302-1} with Ada.Strings.Unbounded;
package Ada.Text_IO.Unbounded_IO
   with Global => in out synchronized is
```

4/2
```
   procedure Put
      (File : in File_Type;
       Item : in Strings.Unbounded.Unbounded_String);
```

5/2
```
   procedure Put
      (Item : in Strings.Unbounded.Unbounded_String);
```

6/2
```
   procedure Put_Line
      (File : in File_Type;
       Item : in Strings.Unbounded.Unbounded_String);
```

7/2
```
   procedure Put_Line
      (Item : in Strings.Unbounded.Unbounded_String);
```

8/2
```
   function Get_Line
      (File : in File_Type)
      return Strings.Unbounded.Unbounded_String;
```

9/2
```
   function Get_Line
      return Strings.Unbounded.Unbounded_String;
```

10/2
```
   procedure Get_Line
      (File : in File_Type; Item : out Strings.Unbounded.Unbounded_String);
```

11/2
```
   procedure Get_Line
      (Item : out Strings.Unbounded.Unbounded_String);
```

12/2
```
end Ada.Text_IO.Unbounded_IO;
```

13/2 {*AI95-00301-01*} For an item of type Unbounded_String, the following subprograms are provided:

```
procedure Put                                                                    14/2
   (File : in File_Type;
    Item : in Strings.Unbounded.Unbounded_String);
```

{*AI95-00301-01*} Equivalent to Text_IO.Put (File, Strings.Unbounded.To_String(Item)); 15/2

```
procedure Put                                                                    16/2
   (Item : in Strings.Unbounded.Unbounded_String);
```

{*AI95-00301-01*} Equivalent to Text_IO.Put (Strings.Unbounded.To_String(Item)); 17/2

```
procedure Put_Line                                                               18/2
   (File : in File_Type;

   return Strings.Unbounded.Unbounded_String;
```

{*AI95-00301-01*} Returns Strings.Unbounded.To_Unbounded_String(Text_IO.Get_Line); 25/2

```
procedure Get_Line                                                               26/2
   (File : in File_Type; Item : out Strings.Unbounded.Unbounded_String);
```

{*AI95-00301-01*} Equivalent to Item := Get_Line (File); 27/2

```
procedure Get_Line                                                               28/2
   (Item : out Strings.Unbounded.Unbounded_String);
```

{*AI95-00301-01*} Equivalent to Item := Get_Line; 29/2

Extensions to Ada 95

{*AI95-00301-01*} Package Text_IO.Unbounded_IO is new. 29.a/2

A.11 Wide Text Input-Output and Wide Wide Text Input-Output

{*AI95-00285-01*} The packages Wide_Text_IO and Wide_Wide_Text_IO provide facilities for input and output in human-readable form. Each file is read or written sequentially, as a sequence of wide characters (or wide wide characters) grouped into lines, and as a sequence of lines grouped into pages. 1/2

Static Semantics

{*AI95-00285-01*} {*AI95-00301-01*} The specification of package Wide_Text_IO is the same as that for Text_IO, except that in each Get, Look_Ahead, Get_Immediate, Get_Line, Put, and Put_Line subprogram, any occurrence of Character is replaced by Wide_Character, and any occurrence of String is replaced by Wide_String. Nongeneric equivalents of Wide_Text_IO.Integer_IO and Wide_Text_IO.-Float_IO are provided (as for Text_IO) for each predefined numeric type, with names such as Ada.Integer_Wide_Text_IO, Ada.Long_Integer_Wide_Text_IO, Ada.Float_Wide_Text_IO, Ada.Long_-Float_Wide_Text_IO. 2/2

{*AI95-00285-01*} {*AI95-00301-01*} The specification of package Wide_Wide_Text_IO is the same as that for Text_IO, except that in each Get, Look_Ahead, Get_Immediate, Get_Line, Put, and Put_Line subprogram, any occurrence of Character is replaced by Wide_Wide_Character, and any occurrence of 3/2

String is replaced by Wide_Wide_String. Nongeneric equivalents of Wide_Wide_Text_IO.Integer_IO and Wide_Wide_Text_IO.Float_IO are provided (as for Text_IO) for each predefined numeric type, with names such as Ada.Integer_Wide_Wide_Text_IO, Ada.Long_Integer_Wide_Wide_Text_IO, Ada.Float_-Wide_Wide_Text_IO, Ada.Long_Float_Wide_Wide_Text_IO.

4/3 {*AI95-00285-01*} {*AI95-00428-01*} {*AI05-0004-1*} {*AI05-0092-1*} The specification of package Wide_Text_IO.Wide_Bounded_IO is the same as that for Text_IO.Bounded_IO, except that any occurrence of Bounded_String is replaced by Bounded_Wide_String, and any occurrence of package Bounded is replaced by Wide_Bounded. The specification of package Wide_Wide_-Text_IO.Wide_Wide_Bounded_IO is the same as that for Text_IO.Bounded_IO, except that any occurrence of Bounded_String is replaced by Bounded_Wide_Wide_String, and any occurrence of package Bounded is replaced by Wide_Wide_Bounded.

4.a/3 **To be honest:** {*AI05-0005-1*} “package Bounded” refers to both the package Ada.Strings.Bounded and the formal package parameter named Bounded.

5/3 {*AI95-00285-01*} {*AI95-00301-01*} {*AI05-0092-1*} The specification of package Wide_Text_IO.-Wide_Unbounded_IO is the same as that for Text_IO.Unbounded_IO, except that any occurrence of Unbounded_String is replaced by Unbounded_Wide_String, and any occurrence of package Unbounded is replaced by Wide_Unbounded. The specification of package Wide_Wide_Text_IO.Wide_Wide_-Unbounded_IO is the same as that for Text_IO.Unbounded_IO, except that any occurrence of Unbounded_String is replaced by Unbounded_Wide_Wide_String, and any occurrence of package Unbounded is replaced by Wide_Wide_Unbounded.

Extensions to Ada 83

5.a Support for Wide_Character and Wide_String I/O is new in Ada 95.

Extensions to Ada 95

5.b/2 {*AI95-00285-01*} Package Wide_Wide_Text_IO is new. Be glad it wasn't called Double_Wide_Text_IO (for use in trailer parks) or Really_Wide_Text_IO.

5.c/2 {*AI95-00301-01*} Packages Wide_Text_IO.Wide_Unbounded_IO and Wide_Wide_Text_IO.Wide_Wide_Unbounded_IO are also new.

5.d/2 {*AI95-00428-01*} Packages Wide_Text_IO.Wide_Bounded_IO and Wide_Wide_Text_IO.Wide_Wide_Bounded_IO are new as well.

Wording Changes from Ada 2005

5.e/3 {*AI05-0092-1*} **Correction**: Corrected the names of various entities in the above description. Since the previously named entities don't exist and the intent is obvious, this is just considered a presentation change.

A.12 Stream Input-Output

1/2 {*AI95-00285-01*} The packages Streams.Stream_IO, Text_IO.Text_Streams, Wide_Text_IO.Text_Streams, and Wide_Wide_Text_IO.Text_Streams provide stream-oriented operations on files.

Wording Changes from Ada 95

1.a/2 {*AI95-00285-01*} Included package Wide_Wide_Text_IO.Text_Streams in this description.

A.12.1 The Package Streams.Stream_IO

1 [The subprograms in the child package Streams.Stream_IO provide control over stream files. Access to a stream file is either sequential, via a call on Read or Write to transfer an array of stream elements, or positional (if supported by the implementation for the given file), by specifying a relative index for an

element. Since a stream file can be converted to a Stream_Access value, calling stream-oriented attribute subprograms of different element types with the same Stream_Access value provides heterogeneous input-output.] See 13.13 for a general discussion of streams.

Static Semantics

{*8652/0055*} {*AI95-00026-01*} The elements of a stream file are stream elements. If positioning is supported for the specified external file, a current index and current size are maintained for the file as described in A.8. If positioning is not supported, a current index is not maintained, and the current size is implementation defined. 1.1/1

Implementation defined: Current size for a stream file for which positioning is not supported. 1.a.1/1

The library package Streams.Stream_IO has the following declaration: 2

```
{AI05-0283-1} {AI12-0302-1} with Ada.IO_Exceptions;                                    3/5

{*AI95-00283-01*} The End_Of_File function: 28.1/2

- Propagates Mode_Error if the mode of the file is not In_File; 28.2/2
- {*AI05-0264-1*} If positioning is supported for the given external file, the function returns True if the current index exceeds the size of the external file; otherwise, it returns False; 28.3/3
- {*AI05-0264-1*} If positioning is not supported for the given external file, the function returns True if no more elements can be read from the given file; otherwise, it returns False. 28.4/3

{*8652/0055*} {*AI95-00026-01*} {*AI95-00085-01*} The Set_Mode procedure sets the mode of the file. If the new mode is Append_File, the file is positioned to its end; otherwise, the position in the file is unchanged. 28.5/2

This paragraph was deleted.{*8652/0055*} {*AI95-00026-01*} {*AI12-0130-1*} 28.6/4

{*8652/0056*} {*AI95-00001-01*} The Stream function returns a Stream_Access result from a File_Type object, thus allowing the stream-oriented attributes Read, Write, Input, and Output to be used on the same file for multiple types. Stream propagates Status_Error if File is not open. 29/1

{*AI95-00256-01*} The procedures Read and Write are equivalent to the corresponding operations in the package Streams. Read propagates Mode_Error if the mode of File is not In_File. Write propagates Mode_Error if the mode of File is not Out_File or Append_File. The Read procedure with a Positive_Count parameter starts reading at the specified index. The Write procedure with a Positive_Count parameter starts writing at the specified index. For a file that supports positioning, Read without a Positive_Count parameter starts reading at the current index, and Write without a Positive_Count parameter starts writing at the current index. 30/2

{*8652/0055*} {*AI95-00026-01*} The Size function returns the current size of the file. 30.1/1

{*8652/0055*} {*AI95-00026-01*} The Index function returns the current index. 31/1

This paragraph was deleted. 31.a/1

The Set_Index procedure sets the current index to the specified value. 32

{*8652/0055*} {*AI95-00026-01*} If positioning is supported for the external file, the current index is maintained as follows: 32.1/1

- {*8652/0055*} {*AI95-00026-01*} For Open and Create, if the Mode parameter is Append_File, the current index is set to the current size of the file plus one; otherwise, the current index is set to one. 32.2/1
- {*8652/0055*} {*AI95-00026-01*} For Reset, if the Mode parameter is Append_File, or no Mode parameter is given and the current mode is Append_File, the current index is set to the current size of the file plus one; otherwise, the current index is set to one. 32.3/1
- {*8652/0055*} {*AI95-00026-01*} For Set_Mode, if the new mode is Append_File, the current index is set to current size plus one; otherwise, the current index is unchanged. 32.4/1
- {*8652/0055*} {*AI95-00026-01*} For Read and Write without a Positive_Count parameter, the current index is incremented by the number of stream elements read or written. 32.5/1
- {*8652/0055*} {*AI95-00026-01*} For Read and Write with a Positive_Count parameter, the value of the current index is set to the value of the Positive_Count parameter plus the number of stream elements read or written. 32.6/1

33 If positioning is not supported for the given file, then a call of Index or Set_Index propagates Use_Error. Similarly, a call of Read or Write with a Positive_Count parameter propagates Use_Error.

33.a/2 **Implementation Note:** {*AI95-00085-01*} It is permissible for an implementation to implement mode Append_File using the Unix append mode (the O_APPEND bit). Such an implementation does not support positioning when the mode is Append_File, and therefore the operations listed above must raise Use_Error. This is acceptable as there is no requirement that any particular file support positioning; therefore it is acceptable that a file support positioning when opened with mode Out_File, and the same file not support positioning when opened with mode Append_File. But it is not acceptable for a file to support positioning (by allowing the above operations), but to do something other than the defined semantics (that is, always write at the end, even when explicitly commanded to write somewhere else).

Paragraphs 34 through 36 were deleted.

Erroneous Execution

36.1/1 {*8652/0056*} {*AI95-00001-01*} If the File_Type object passed to the Stream function is later closed or finalized, and the stream-oriented attributes are subsequently called (explicitly or implicitly) on the Stream_Access value returned by Stream, execution is erroneous. This rule applies even if the File_Type object was opened again after it had been closed.

36.a.1/1 **Reason:** These rules are analogous to the rule for the result of the Current_Input, Current_Output, and Current_Error functions. These rules make it possible to represent a value of (some descendant of) Root_Stream_Type which represents a file as an access value, with a null value corresponding to a closed file.

Inconsistencies With Ada 95

36.a/3 {*AI95-00283-01*} {*AI05-0005-1*} **Amendment Correction:** The description of the subprograms for managing files was corrected so that they do not require truncation of the external file — a stream file is not a sequential file. An Ada 95 program that expects truncation of the stream file might not work under Ada 2005. Note that the Ada 95 standard was ambiguous on this point (the normative wording seemed to require truncation, but didn't explain where; the AARM notes seemed to expect behavior like Direct_IO), and implementations varied widely. Therefore, as a practical matter, code that depends on stream truncation might not work even in Ada 95; deleting the file before opening it provides truncation that works in both Ada 95 and Ada 2005.

Incompatibilities With Ada 95

36.b/2 {*AI95-00360-01*} **Amendment Correction:** Stream_IO.File_Type is defined to need finalization. If the restriction No_Nested_Finalization (see D.7) applies to the partition, and File_Type does not have a controlled part, it will not be allowed in local objects in Ada 2005 whereas it would be allowed in original Ada 95. Such code is not portable, as another Ada compiler may have a controlled part in File_Type, and thus would be illegal.

Wording Changes from Ada 95

36.c/2 {*8652/0051*} {*AI95-00057-01*} **Corrigendum:** Corrected the parameter mode of Flush; otherwise it could not be used on Standard_Output.

36.d/2 {*8652/0055*} {*AI95-00026-01*} {*AI95-00256-01*} **Corrigendum:** Added wording to describe the effects of the various operations on the current index. The Amendment adds an explanation of the use of current index for Read and Write.

36.e/2 {*8652/0056*} {*AI95-00001-01*} **Corrigendum:** Clarified that Stream can raise Status_Error, and clarified that using a Stream_Access whose file has been closed is erroneous.

36.f/2 {*AI95-00085-01*} Clarified that Set_Mode can be called with the current mode.

Extensions to Ada 2005

36.g/3 {*AI05-0283-1*} Package Ada.Streams.Stream_IO is now preelaborated, allowing it to be used in more contexts (including in distributed systems). Note that it is *not* a remote types package; File_Type objects cannot be passed between partitions.

Incompatibilities With Ada 2012

36.h/5 {*AI12-0021-1*} The Wide_File_Names and Wide_Wide_File_Names nested packages are newly added to Ada.Stream_IO. Therefore, a use clause conflict is possible; see the introduction of Annex A for more on this topic.

Extensions to Ada 2012

{*AI12-0102-1*} **Corrigendum:** Type Ada.Streams.Stream_IO.File_Type now has preelaborable initialization. This allows declaring library-level file objects in preelaborable packages (an oversight from the change above). 36.i/4

Wording Changes from Ada 2012

{*AI12-0130-1*} **Corrigendum:** The definition of the Flush procedure was moved to A.8.2, so that it could be shared by all of the I/O packages. 36.j/4

A.12.2 The Package Text_IO.Text_Streams

The package Text_IO.Text_Streams provides a function for treating a text file as a stream. 1

Static Semantics

The library package Text_IO.Text_Streams has the following declaration: 2

```
{AI12-0302-1} with Ada.Streams;                                                    3/5
package Ada.Text_IO.Text_Streams
   with Global => in out synchronized is
   type Stream_Access is access all Streams.Root_Stream_Type'Class;

   function Stream (File : in File_Type) return Stream_Access;                     4
end Ada.Text_IO.Text_Streams;
```

The Stream function has the same effect as the corresponding function in Streams.Stream_IO. 5

NOTE 1 The ability to obtain a stream for a text file allows Current_Input, Current_Output, and Current_Error to be processed with the functionality of streams, including the mixing of text and binary input-output, and the mixing of binary input-output for different types. 6

NOTE 2 Performing operations on the stream associated with a text file does not affect the column, line, or page counts. 7

A.12.3 The Package Wide_Text_IO.Text_Streams

The package Wide_Text_IO.Text_Streams provides a function for treating a wide text file as a stream. 1

Static Semantics

The library package Wide_Text_IO.Text_Streams has the following declaration: 2

```
{AI12-0302-1} with Ada.Streams;                                                    3/5
package Ada.Wide_Text_IO.Text_Streams
   with Global => in out synchronized is
   type Stream_Access is access all Streams.Root_Stream_Type'Class;

   function Stream (File : in File_Type) return Stream_Access;                     4
end Ada.Wide_Text_IO.Text_Streams;
```

The Stream function has the same effect as the corresponding function in Streams.Stream_IO. 5

A.12.4 The Package Wide_Wide_Text_IO.Text_Streams

{*AI95-00285-01*} The package Wide_Wide_Text_IO.Text_Streams provides a function for treating a wide wide text file as a stream. 1/2

Static Semantics

{*AI95-00285-01*} The library package Wide_Wide_Text_IO.Text_Streams has the following declaration: 2/2

```
{AI12-0302-1} with Ada.Streams;                                                    3/5
package Ada.Wide_Wide_Text_IO.Text_Streams
   with Global => in out synchronized is
   type Stream_Access is access all Streams.Root_Stream_Type'Class;
```

4/2
```
      function Stream (File : in File_Type) return Stream_Access;
   end Ada.Wide_Wide_Text_IO.Text_Streams;
```

5/2 {*AI95-00285-01*} The Stream function has the same effect as the corresponding function in Streams.Stream_IO.

Extensions to Ada 95

5.a/2 {*AI95-00285-01*} Package Wide_Wide_Text_IO.Text_Streams is new.

A.13 Exceptions in Input-Output

1/5 {*AI12-0445-1*} The package IO_Exceptions defines the exceptions used by the predefined input-output packages.

Static Semantics

2 The library package IO_Exceptions has the following declaration:

3/5
```
   {AI12-0414-1} package Ada.IO_Exceptions
      with Pure is
```

4
```
      Status_Error : exception;
      Mode_Error   : exception;
      Name_Error   : exception;
      Use_Error    : exception;
      Device_Error : exception;
      End_Error    : exception;
      Data_Error   : exception;
      Layout_Error : exception;
```

5
```
   end Ada.IO_Exceptions;
```

6 If more than one error condition exists, the corresponding exception that appears earliest in the following list is the one that is propagated.

7 The exception Status_Error is propagated by an attempt to operate upon a file that is not open, and by an attempt to open a file that is already open.

8 The exception Mode_Error is propagated by an attempt to read from, or test for the end of, a file whose current mode is Out_File or Append_File, and also by an attempt to write to a file whose current mode is In_File. In the case of Text_IO, the exception Mode_Error is also propagated by specifying a file whose current mode is Out_File or Append_File in a call of Set_Input, Skip_Line, End_Of_Line, Skip_Page, or End_Of_Page; and by specifying a file whose current mode is In_File in a call of Set_Output, Set_Line_Length, Set_Page_Length, Line_Length, Page_Length, New_Line, or New_Page.

9 The exception Name_Error is propagated by a call of Create or Open if the string given for the parameter Name does not allow the identification of an external file. For example, this exception is propagated if the string is improper, or, alternatively, if either none or more than one external file corresponds to the string.

10 The exception Use_Error is propagated if an operation is attempted that is not possible for reasons that depend on characteristics of the external file. For example, this exception is propagated by the procedure Create, among other circumstances, if the given mode is Out_File but the form specifies an input only device, if the parameter Form specifies invalid access rights, or if an external file with the given name already exists and overwriting is not allowed.

11 The exception Device_Error is propagated if an input-output operation cannot be completed because of a malfunction of the underlying system.

12 The exception End_Error is propagated by an attempt to skip (read past) the end of a file.

The exception Data_Error can be propagated by the procedure Read (or by the Read attribute) if the element read cannot be interpreted as a value of the required subtype. This exception is also propagated by a procedure Get (defined in the package Text_IO) if the input character sequence fails to satisfy the required syntax, or if the value input does not belong to the range of the required subtype. 13

The exception Layout_Error is propagated (in text input-output) by Col, Line, or Page if the value returned exceeds Count'Last. The exception Layout_Error is also propagated on output by an attempt to set column or line numbers in excess of specified maximum line or page lengths, respectively (excluding the unbounded cases). It is also propagated by an attempt to Put too many characters to a string. 14

{*AI05-0262-1*} These exceptions are also propagated by various other language-defined packages and operations, see the definition of those entities for other reasons that these exceptions are propagated. 14.1/3

Reason: {*AI05-0299-1*} This subclause is based in Ada 95. Later versions of Ada (starting with Technical Corrigendum 1) have added a number of additional places and reasons that cause these exceptions. In particular, TC1 says that stream attributes need to raise End_Error in some circumstances; Amendment 1 adds Ada.Directories and a number of new places and reasons that Name_Error and Use_Error are raised. There are more. We don't want to try to update this text (or even this note!) for every possible reason and place that might raise one of these exceptions, so we add this blanket statement. 14.a/3

Documentation Requirements

The implementation shall document the conditions under which Name_Error, Use_Error and Device_Error are propagated. 15

Documentation Requirement: The conditions under which Io_Exceptions.Name_Error, Io_Exceptions.Use_Error, and Io_Exceptions.Device_Error are propagated. 15.a/2

Implementation Permissions

{*AI12-0444-1*} When the associated check is complex, it is optional to propagate Data_Error as part of a procedure Read (or the Read attribute) when the value read cannot be interpreted as a value of the required subtype. 16/5

Ramification: An example where the implementation may choose not to perform the check is an enumeration type with a representation clause with “holes” in the range of internal codes. 16.a

Erroneous Execution

[If the element read by the procedure Read (or by the Read attribute) cannot be interpreted as a value of the required subtype, but this is not detected and Data_Error is not propagated, then the resulting value can be abnormal, and subsequent references to the value can lead to erroneous execution, as explained in 13.9.1.] 17

A.14 File Sharing

Dynamic Semantics

It is not specified by the language whether the same external file can be associated with more than one file object. If such sharing is supported by the implementation, the following effects are defined: 1

- Operations on one text file object do not affect the column, line, and page numbers of any other file object. 2
- *This paragraph was deleted.*{*8652/0057*} {*AI95-00050-01*} 3/1
- For direct and stream files, the current index is a property of each file object; an operation on one file object does not affect the current index of any other file object. 4
- For direct and stream files, the current size of the file is a property of the external file. 5

6 All other effects are identical.

Wording Changes from Ada 95

6.a/2 {*8652/0057*} {*AI95-00050-01*} **Corrigendum:** Removed the incorrect statement that the external files associated with the standard input, standard output, and standard error files are distinct.

A.15 The Package Command_Line

1 The package Command_Line allows a program to obtain the values of its arguments and to set the exit status code to be returned on normal termination.

1.a/2 **Implementation defined:** The meaning of Argument_Count, Argument, and Command_Name for package Command_Line. The bounds of type Command_Line.Exit_Status.

Static Semantics

2 The library package Ada.Command_Line has the following declaration:

3/5
```
{AI12-0241-1} package Ada.Command_Line
  with Preelaborate, Nonblocking, Global => in out synchronized is
```

4
```
   function Argument_Count return Natural;
```

5
```
   function Argument (Number : in Positive) return String;
```

6
```
   function Command_Name return String;
```

7
```
   type Exit_Status is implementation-defined integer type;
```

8
```
   Success : constant Exit_Status;
   Failure : constant Exit_Status;
```

9
```
   procedure Set_Exit_Status (Code : in Exit_Status);
```

10
```
private
   ... -- not specified by the language
end Ada.Command_Line;
```

11
```
function Argument_Count return Natural;
```

12/3 {*AI05-0264-1*} If the external execution environment supports passing arguments to a program, then Argument_Count returns the number of arguments passed to the program invoking the function. Otherwise, it returns 0. The meaning of "number of arguments" is implementation defined.

13
```
function Argument (Number : in Positive) return String;
```

14/5 {*AI12-0259-1*} If the external execution environment supports passing arguments to a program, then Argument returns an implementation-defined value with lower bound 1 corresponding to the argument at relative position Number. If Number is outside the range 1..Argument_Count, then Constraint_Error is propagated.

14.a **Ramification:** If the external execution environment does not support passing arguments to a program, then Argument(N) for any N will raise Constraint_Error, since Argument_Count is 0.

15
```
function Command_Name return String;
```

16/5 {*AI05-0264-1*} {*AI12-0259-1*} If the external execution environment supports passing arguments to a program, then Command_Name returns an implementation-defined value with lower bound 1 corresponding to the name of the command invoking the program; otherwise, Command_Name returns the null string.

```
type Exit_Status is implementation-defined integer type;
```
16.1/1

The type Exit_Status represents the range of exit status values supported by the external execution environment. The constants Success and Failure correspond to success and failure, respectively. 17

```
procedure Set_Exit_Status (Code : in Exit_Status);
```
18

If the external execution environment supports returning an exit status from a program, then Set_Exit_Status sets Code as the status. Normal termination of a program returns as the exit status the value most recently set by Set_Exit_Status, or, if no such value has been set, then the value Success. If a program terminates abnormally, the status set by Set_Exit_Status is ignored, and an implementation-defined exit status value is set. 19

If the external execution environment does not support returning an exit value from a program, then Set_Exit_Status does nothing. 20

Implementation Permissions

An alternative declaration is allowed for package Command_Line if different functionality is appropriate for the external execution environment. 21

NOTE Argument_Count, Argument, and Command_Name correspond to the C language's argc, argv[n] (for n>0) and argv[0], respectively. 22

To be honest: The correspondence of Argument_Count to argc is not direct — argc would be one more than Argument_Count, since the argc count includes the command name, whereas Argument_Count does not. 22.a

Extensions to Ada 83

{*AI05-0299-1*} This subclause is new in Ada 95. 22.b/3

Wording Changes from Ada 2012

{*AI12-0259-1*} **Correction:** Defined the lower bound of functions Argument and Command_Name. This could be inconsistent if someone depended on the lower bound of these routines (and it wasn't 1), but such code was never portable (even to later versions of the same implementation). Thus we don't document it as an inconsistency. 22.c/5

A.15.1 The Packages Wide_Command_Line and Wide_Wide_Command_Line

{*AI12-0021-1*} The packages Wide_Command_Line and Wide_Wide_Command_Line allow a program to obtain the values of its arguments and to set the exit status code to be returned on normal termination. 1/5

Static Semantics

{*AI12-0021-1*} The specification of package Wide_Command_Line is the same as for Command_Line, except that each occurrence of String is replaced by Wide_String. 2/5

{*AI12-0021-1*} The specification of package Wide_Wide_Command_Line is the same as for Command_Line, except that each occurrence of String is replaced by Wide_Wide_String. 3/5

Extensions to Ada 2012

{*AI12-0021-1*} These packages are new. 3.a/5

A.16 The Package Directories

{*AI95-00248-01*} The package Directories provides operations for manipulating files and directories, and their names. 1/2

1.a/3 **Discussion:** {*AI05-0299-1*} The notes for this subclause contain the expected interpretations of some of the operations on various target systems. “Unix” refers to the UNIX® operating system, and in most cases also covers Unix-like systems such as Linux and POSIX. “Windows®” refers to the Microsoft® Windows® 2000 operating system and usually also covers most other versions that use the Win32 API.

Static Semantics

2/2 {*AI95-00248-01*} The library package Directories has the following declaration:

3/5
```
{AI12-0302-1} with Ada.IO_Exceptions;
with Ada.Calendar;
package Ada.Directories
   with Global => in out synchronized is
```

4/2
```
   -- Directory and file operations:
```

5/2
```
   function Current_Directory return String;
```

6/2
```
   procedure Set_Directory (Directory : in String);
```

7/2
```
   procedure Create_Directory (New_Directory : in String;
                               Form          : in String := "");
```

8/2
```
   procedure Delete_Directory (Directory : in String);
```

9/2
```
   procedure Create_Path (New_Directory : in String;
                          Form          : in String := "");
```

10/2
```
   procedure Delete_Tree (Directory : in String);
```

11/2
```
   procedure Delete_File (Name : in String);
```

12/2
```
   procedure Rename (Old_Name, New_Name : in String);
```

13/2
```
   procedure Copy_File (Source_Name,
                        Target_Name : in String;
                        Form        : in String := "");
```

14/2
```
   -- File and directory name operations:
```

15/5
```
   {AI12-0241-1}    function Full_Name (Name : in String) return String
         with Nonblocking;
```

16/5
```
   {AI12-0241-1}    function Simple_Name (Name : in String) return String
         with Nonblocking;
```

17/5
```
   {AI12-0241-1}    function Containing_Directory (Name : in String) return String
         with Nonblocking;
```

18/5
```
   {AI12-0241-1}    function Extension (Name : in String) return String
         with Nonblocking;
```

19/5
```
   {AI12-0241-1}    function Base_Name (Name : in String) return String
         with Nonblocking;
```

20/5
```
   {AI12-0241-1}    function Compose (Containing_Directory : in String := "";
                        Name                : in String;
                        Extension           : in String := "") return String
         with Nonblocking;
```

20.1/3
```
   {AI05-0049-1}    type Name_Case_Kind is
         (Unknown, Case_Sensitive, Case_Insensitive, Case_Preserving);
```

20.2/3
```
   {AI05-0049-1}    function Name_Case_Equivalence (Name : in String) return
   Name_Case_Kind;
```

21/2
```
   -- File and directory queries:
```

22/2
```
   type File_Kind is (Directory, Ordinary_File, Special_File);
```

23/2
```
   type File_Size is range 0 .. implementation-defined;
```

24/2
```
   function Exists (Name : in String) return Boolean;
```

25/2
```
   function Kind (Name : in String) return File_Kind;
```

26/2
```
   function Size (Name : in String) return File_Size;
```

27/2
```
   function Modification_Time (Name : in String) return Ada.Calendar.Time;
```

28/2
```
   -- Directory searching:
```

```
   type Directory_Entry_Type is limited private;                                    29/2
   type Filter_Type is array (File_Kind) of Boolean;                                30/2
   type Search_Type is limited private;                                             31/2
   procedure Start_Search (Search    : in out Search_Type;                          32/2
                           Directory : in String;
                           Pattern   : in String;
                           Filter    : in Filter_Type := (others => True));
   procedure End_Search (Search : in out Search_Type);                               33/2
   function More_Entries (Search : in Search_Type) return Boolean;                  34/2
   procedure Get_Next_Entry (Search : in out Search_Type;                           35/2
                             Directory_Entry : out Directory_Entry_Type);
{AI12-0286-1}    procedure Search (                                                  36/5
      Directory : in String;
      Pattern   : in String;
      Filter    : in Filter_Type := (others => True);
      Process   : not null access procedure (
          Directory_Entry : in Directory_Entry_Type))
      with Allows_Exit;
   -- Operations on Directory Entries:                                              37/2
   function Simple_Name (Directory_Entry : in Directory_Entry_Type)                 38/2
       return String;
   function Full_Name (Directory_Entry : in Directory_Entry_Type)                   39/2
       return String;
   function Kind (Directory_Entry : in Directory_Entry_Type)                        40/2
       return File_Kind;
   function Size (Directory_Entry : in Directory_Entry_Type)                        41/2
       return File_Size;

   Device_Error : exception renames Ada.IO_Exceptions.Device_Error;
{AI05-0092-1} private                                                               44/3
   ... -- not specified by the language
end Ada.Directories;
```

{*AI95-00248-01*} External files may be classified as directories, special files, or ordinary files. A *directory* is an external file that is a container for files on the target system. A *special file* is an external file that cannot be created or read by a predefined Ada input-output package. External files that are not special files or directories are called *ordinary files*. 45/2

Ramification: A directory is an external file, although it may not have a name on some targets. A directory is not a special file, as it can be created and read by Directories. 45.a/2

Discussion: Devices and soft links are examples of special files on Windows® and Unix. 45.b/2

Even if an implementation provides a package to create and read soft links, such links are still special files. 45.c/2

{*AI95-00248-01*} A *file name* is a string identifying an external file. Similarly, a *directory name* is a string identifying a directory. The interpretation of file names and directory names is implementation defined. 46/2

Implementation defined: The interpretation of file names and directory names. 46.a/2

{*AI95-00248-01*} The *full name* of an external file is a full specification of the name of the file. If the external environment allows alternative specifications of the name (for example, abbreviations), the full name should not use such alternatives. A full name typically will include the names of all of the directories that contain the item. The *simple name* of an external file is the name of the item, not including 47/2

any containing directory names. Unless otherwise specified, a file name or directory name parameter in a call to a predefined Ada input-output subprogram can be a full name, a simple name, or any other form of name supported by the implementation.

47.a/2 **Discussion:** The full name on Unix is a complete path to the root. For Windows®, the full name includes a complete path, as well as a disk name ("C:") or network share name. For both systems, the simple name is the part of the name following the last '/' (or '\' for Windows®). For example, in the name "/usr/randy/ada-directories.ads", "ada-directories.ads" is the simple name.

47.b/2 **Ramification:** It is possible for a file or directory name to be neither a full name nor a simple name. For instance, the Unix name "../parent/myfile" is neither a full name nor a simple name.

47.1/5 {*AI12-0337-1*} A *root directory* is a directory that has no containing directory.

47.c/5 **Implementation Note:** For Unix and Unix-like systems, "/" is the root. For Windows®, "C:\" and "\\Computer\Share" are roots.

48/2 {*AI95-00248-01*} The *default directory* is the directory that is used if a directory or file name is not a full name (that is, when the name does not fully identify all of the containing directories).

48.a/2 **Discussion:** The default directory is the one maintained by the familiar “cd” command on Unix and Windows®. Note that Windows® maintains separate default directories for each disk drive; implementations should use the natural implementation.

49/2 {*AI95-00248-01*} A *directory entry* is a single item in a directory, identifying a single external file (including directories and special files).

50/2 {*AI95-00248-01*} For each function that returns a string, the lower bound of the returned value is 1.

51/2 {*AI95-00248-01*} The following file and directory operations are provided:

52/2
```
function Current_Directory return String;
```

53/2 Returns the full directory name for the current default directory. The name returned shall be suitable for a future call to Set_Directory. The exception Use_Error is propagated if a default directory is not supported by the external environment.

54/2
```
procedure Set_Directory (Directory : in String);
```

55/2 Sets the current default directory. The exception Name_Error is propagated if the string given as Directory does not identify an existing directory. The exception Use_Error is propagated if the external environment does not support making Directory (in the absence of Name_Error) a default directory.

56/2
```
procedure Create_Directory (New_Directory : in String;
                           Form          : in String := "");
```

57/2 Creates a directory with name New_Directory. The Form parameter can be used to give system-dependent characteristics of the directory; the interpretation of the Form parameter is implementation defined. A null string for Form specifies the use of the default options of the implementation of the new directory. The exception Name_Error is propagated if the string given as New_Directory does not allow the identification of a directory. The exception Use_Error is propagated if the external environment does not support the creation of a directory with the given name (in the absence of Name_Error) and form.

58/2
```
procedure Delete_Directory (Directory : in String);
```

59/3 {*AI05-0231-1*} Deletes an existing empty directory with name Directory. The exception Name_Error is propagated if the string given as Directory does not identify an existing directory. The exception Use_Error is propagated if the directory is not empty or the external environment does not support the deletion of the directory with the given name (in the absence of Name_Error).

```
procedure Create_Path (New_Directory : in String;                    60/2
                       Form          : in String := "");
```

{*AI05-0271-1*} Creates zero or more directories with name New_Directory. Each nonexistent directory named by New_Directory is created.[For example, on a typical Unix system, Create_Path ("/usr/me/my"); would create directory "me" in directory "usr", then create directory "my" in directory "me".] The Form parameter can be used to give system-dependent characteristics of the directory; the interpretation of the Form parameter is implementation defined. A null string for Form specifies the use of the default options of the implementation of the new directory. The exception Name_Error is propagated if the string given as New_Directory does not allow the identification of any directory. The exception Use_Error is propagated if the external environment does not support the creation of any directories with the given name (in the absence of Name_Error) and form. If Use_Error is propagated, it is unspecified whether a portion of the directory path is created. 61/3

```
procedure Delete_Tree (Directory : in String);                       62/2
```

Deletes an existing directory with name Directory. The directory and all of its contents (possibly including other directories) are deleted. The exception Name_Error is propagated if the string given as Directory does not identify an existing directory. The exception Use_Error is propagated if the external environment does not support the deletion of the directory or some portion of its contents with the given name (in the absence of Name_Error). If Use_Error is propagated, it is unspecified whether a portion of the contents of the directory is deleted. 63/2

```
procedure Delete_File (Name : in String);                            64/2
```

Deletes an existing ordinary or special file with name Name. The exception Name_Error is propagated if the string given as Name does not identify an existing ordinary or special external file. The exception Use_Error is propagated if the external environment does not support the deletion of the file with the given name (in the absence of Name_Error). 65/2

```
procedure Rename (Old_Name, New_Name : in String);                   66/2
```

{*AI05-0231-1*} Renames an existing external file (including directories) with name Old_Name to New_Name. The exception Name_Error is propagated if the string given as Old_Name does not identify an existing external file or if the string given as New_Name does not allow the identification of an external file. The exception Use_Error is propagated if the external environment does not support the renaming of the file with the given name (in the absence of Name_Error). In particular, Use_Error is propagated if a file or directory already exists with name New_Name. 67/3

Implementation Note: This operation is expected to work within a single directory, and implementers are encouraged to support it across directories on a single device. Copying files from one device to another is discouraged (that's what Copy_File is for). However, there is no requirement to detect file copying by the target system. If the target system has an API that gives that for “free”, it can be used. For Windows®, for instance, MoveFile can be used to implement Rename. 67.a/2

```
{AI05-0092-1} procedure Copy_File (Source_Name,                      68/3
                      Target_Name : in String;
                      Form        : in String := "");
```

{*AI05-0271-1*} Copies the contents of the existing external file with name Source_Name to an external file with name Target_Name. The resulting external file is a duplicate of the source external file. The Form parameter can be used to give system-dependent characteristics of the resulting external file; the interpretation of the Form parameter is implementation defined. Exception Name_Error is propagated if the string given as Source_Name does not identify an existing external ordinary or special file, or if the string given as Target_Name does not allow the identification of an external file. The exception Use_Error is propagated if the external 69/3

environment does not support creating the file with the name given by Target_Name and form given by Form, or copying of the file with the name given by Source_Name (in the absence of Name_Error). If Use_Error is propagated, it is unspecified whether a portion of the file is copied.

69.a/2 **Ramification:** Name_Error is always raised if Source_Name identifies a directory. It is up to the implementation whether special files can be copied, or if Use_Error will be raised.

70/2 {*AI95-00248-01*} The following file and directory name operations are provided:

71/2
```
function Full_Name (Name : in String) return String;
```

72/2 Returns the full name corresponding to the file name specified by Name. The exception Name_Error is propagated if the string given as Name does not allow the identification of an external file (including directories and special files).

72.a/2 **Discussion:** Full name means that no abbreviations are used in the returned name, and that it is a full specification of the name. Thus, for Unix and Windows®, the result should be a full path that does not contain any "." or ".." directories. Typically, the default directory is used to fill in any missing information.

73/2
```
function Simple_Name (Name : in String) return String;
```

74/5 {*AI12-0337-1*} {*AI12-0433-1*} Returns the simple name portion of the file name specified by Name. The simple name of a root directory is a name of the root itself. The exception Name_Error is propagated if the string given as Name does not allow the identification of an external file (including directories and special files).

74.a/5 **Discussion:** {*AI12-0337-1*} The result of Simple_Name corresponds to the result of the “basename” command on Linux and Unix. If the filename ends with a '/', and is not a root, then “basename” returns the part in front of all of the trailing '/'s. It returns a root intact. The null string is never returned. Similar rules should be used for Windows filenames.

75/2
```
function Containing_Directory (Name : in String) return String;
```

76/2 Returns the name of the containing directory of the external file (including directories) identified by Name. (If more than one directory can contain Name, the directory name returned is implementation defined.) The exception Name_Error is propagated if the string given as Name does not allow the identification of an external file. The exception Use_Error is propagated if the external file does not have a containing directory.

76.a/2 **Discussion:** This is purely a string manipulation function. If Name is not given as a full name, the containing directory probably won't be one, either. For example, if Containing_Directory ("..\AARM\RM-A-8") is called on Windows®, the result should be "..\AARM". If there is no path at all on the name, the result should be "." (which represents the current directory). Use Full_Name on the result of Containing_Directory if the full name is needed.

76.b/5 **Ramification:** {*AI12-0337-1*} Containing_Directory raises Use_Error when passed a string representing a root directory.

77/2
```
function Extension (Name : in String) return String;
```

78/2 Returns the extension name corresponding to Name. The extension name is a portion of a simple name (not including any separator characters), typically used to identify the file class. If the external environment does not have extension names, then the null string is returned. The exception Name_Error is propagated if the string given as Name does not allow the identification of an external file.

78.a/2 **Discussion:** For Unix and Windows®, the extension is the portion of the simple name following the rightmost period. For example, in the simple name "RM-A-8.html", the extension is "html".

79/2
```
function Base_Name (Name : in String) return String;
```

80/2 Returns the base name corresponding to Name. The base name is the remainder of a simple name after removing any extension and extension separators. The exception Name_Error is propagated if the string given as Name does not allow the identification of an external file (including directories and special files).

Discussion: For Unix and Windows®, the base name is the portion of the simple name preceding the rightmost period (except for the special directory names "." and "..", whose Base_Name is "." and ".."). For example, in the simple name "RM-A-8.html", the base name is "RM-A-8". 80.a/2

```
function Compose (Containing_Directory : in String := "";
                  Name                 : in String;
                  Extension            : in String := "") return String;
```
81/2

{*AI05-0264-1*} {*AI12-0337-1*} Returns the name of the external file with the specified Containing_Directory, Name, and Extension. If Extension is the null string, then Name is interpreted as a simple name; otherwise, Name is interpreted as a base name. The exception Name_Error is propagated if: 82/5

- the string given as Containing_Directory is not null and does not allow the identification of a directory; 82.1/5
- the string given as Extension is not null and is not a possible extension; 82.2/5
- the string given as Name is not a possible simple name (if Extension is null) or base name (if Extension is nonnull); or 82.3/5
- {*AI12-0337-1*} the string given as Name is a root directory, and Containing_Directory or Extension is nonnull. 82.4/5

Ramification: The above definition implies that if the Extension is null, for Unix and Windows® no '.' is added to Name. 82.a/2

Discussion: If Name is null, Name_Error should be raised, as nothing is not a possible simple name or base name. 82.b/2

Generally, Compose(Containing_Directory(F), Base_Name(F),Extension(F)) = F. However, this is not true on Unix or Windows® for file names that end with a '.'; Compose(Base_Name("Fooey."),Extension("Fooey.")) = "Fooey". This is not a problem for Windows®, as the names have the same meaning with or without the '.', but these are different names for Unix. Thus, care needs to be taken on Unix; if Extension is null, Base_Name should be avoided. (That's not usually a problem with file names generated by a program.) 82.c/2

```
{AI05-0049-1} function Name_Case_Equivalence (Name : in String) return
Name_Case_Kind;
```
82.5/3

{*AI05-0049-1*} {*AI05-0248-1*} Returns the file name equivalence rule for the directory containing Name. Raises Name_Error if Name is not a full name. Returns Case_Sensitive if file names that differ only in the case of letters are considered different names. If file names that differ only in the case of letters are considered the same name, then Case_Preserving is returned if names have the case of the file name used when a file is created; and Case_Insensitive is returned otherwise. Returns Unknown if the file name equivalence is not known. 82.6/3

Implementation Note: Unix, Linux, and their relatives are Case_Sensitive systems. Microsoft® Windows® is a Case_Preserving system (unless the rarely used POSIX mode is used). Ancient systems like CP/M and early MS-DOS were Case_Insensitive systems (file names were always in UPPER CASE). Unknown is provided in case it is impossible to tell (such as could be the case for network files). 82.c.1/3

{*AI95-00248-01*} The following file and directory queries and types are provided: 83/2

```
type File_Kind is (Directory, Ordinary_File, Special_File);
```
84/2

The type File_Kind represents the kind of file represented by an external file or directory. 85/2

```
type File_Size is range 0 .. implementation-defined;
```
86/2

The type File_Size represents the size of an external file. 87/2

Implementation defined: The maximum value for a file size in Directories. 87.a/2

```
function Exists (Name : in String) return Boolean;
```
88/2

Returns True if an external file represented by Name exists, and False otherwise. The exception Name_Error is propagated if the string given as Name does not allow the identification of an external file (including directories and special files). 89/2

90/2 `function Kind (Name : in String) return File_Kind;`

91/2 Returns the kind of external file represented by Name. The exception Name_Error is propagated if the string given as Name does not allow the identification of an existing external file.

92/2 `function Size (Name : in String) return File_Size;`

93/2 Returns the size of the external file represented by Name. The size of an external file is the number of stream elements contained in the file. If the external file is not an ordinary file, the result is implementation defined. The exception Name_Error is propagated if the string given as Name does not allow the identification of an existing external file. The exception Constraint_Error is propagated if the file size is not a value of type File_Size.

93.a/2 **Implementation defined:** The result for Directories.Size for a directory or special file.

93.b/2 **Discussion:** We allow raising Constraint_Error, so that an implementation for a system with 64-bit file sizes does not need to support full numerics on 64-bit integers just to implement this package. Of course, if 64-bit integers are available on such a system, they should be used when defining type File_Size.

94/2 `function Modification_Time (Name : in String) return Ada.Calendar.Time;`

95/2 Returns the time that the external file represented by Name was most recently modified. If the external file is not an ordinary file, the result is implementation defined. The exception Name_Error is propagated if the string given as Name does not allow the identification of an existing external file. The exception Use_Error is propagated if the external environment does not support reading the modification time of the file with the name given by Name (in the absence of Name_Error).

95.a/2 **Implementation defined:** The result for Directories.Modification_Time for a directory or special file.

96/2 {*AI95-00248-01*} The following directory searching operations and types are provided:

97/2 `type Directory_Entry_Type is limited private;`

98/2 The type Directory_Entry_Type represents a single item in a directory. These items can only be created by the Get_Next_Entry procedure in this package. Information about the item can be obtained from the functions declared in this package. A default-initialized object of this type is invalid; objects returned from Get_Next_Entry are valid.

99/2 `type Filter_Type is array (File_Kind) of Boolean;`

100/2 The type Filter_Type specifies which directory entries are provided from a search operation. If the Directory component is True, directory entries representing directories are provided. If the Ordinary_File component is True, directory entries representing ordinary files are provided. If the Special_File component is True, directory entries representing special files are provided.

101/2 `type Search_Type is limited private;`

102/2 The type Search_Type contains the state of a directory search. A default-initialized Search_Type object has no entries available (function More_Entries returns False). Type Search_Type needs finalization (see 7.6).

103/2
```
procedure Start_Search (Search    : in out Search_Type;
                        Directory : in String;
                        Pattern   : in String;
                        Filter    : in Filter_Type := (others => True));
```

104/3 {*AI05-0092-1*} {*AI05-0262-1*} Starts a search in the directory named by Directory for entries matching Pattern and Filter. Pattern represents a pattern for matching file names. If Pattern is the null string, all items in the directory are matched; otherwise, the interpretation of Pattern is implementation defined. Only items that match Filter will be returned. After a successful call on Start_Search, the object Search may have entries available, but it may have no entries available if

no files or directories match Pattern and Filter. The exception Name_Error is propagated if the string given by Directory does not identify an existing directory, or if Pattern does not allow the identification of any possible external file or directory. The exception Use_Error is propagated if the external environment does not support the searching of the directory with the given name (in the absence of Name_Error). When Start_Search propagates Name_Error or Use_Error, the object Search will have no entries available.

Implementation defined: The interpretation of a nonnull search pattern in Directories. 104.a/2

```
procedure End_Search (Search : in out Search_Type);
```
105/2

Ends the search represented by Search. After a successful call on End_Search, the object Search will have no entries available. 106/2

Ramification: The only way that a call to End_Search could be unsuccessful if Device_Error (see A.13) is raised because of an underlying failure (or bug). 106.a/2

```
function More_Entries (Search : in Search_Type) return Boolean;
```
107/2

Returns True if more entries are available to be returned by a call to Get_Next_Entry for the specified search object, and False otherwise. 108/2

```
procedure Get_Next_Entry (Search : in out Search_Type;
                          Directory_Entry : out Directory_Entry_Type);
```
109/2

{*AI05-0262-1*} Returns the next Directory_Entry for the search described by Search that matches the pattern and filter. If no further matches are available, Status_Error is raised. It is implementation defined as to whether the results returned by this subprogram are altered if the contents of the directory are altered while the Search object is valid (for example, by another program). The exception Use_Error is propagated if the external environment does not support continued searching of the directory represented by Search. 110/3

Implementation defined: The results of a Directories search if the contents of the directory are altered while a search is in progress. 110.a/2

```
{AI12-0286-1} procedure Search (
   Directory : in String;
   Pattern   : in String;
   Filter    : in Filter_Type := (others => True);
   Process   : not null access procedure (
       Directory_Entry : in Directory_Entry_Type))
   with Allows_Exit;
```
111/5

{*AI05-0092-1*} {*AI05-0262-1*} Searches in the directory named by Directory for entries matching Pattern and Filter. The subprogram designated by Process is called with each matching entry in turn. Pattern represents a pattern for matching file names. If Pattern is the null string, all items in the directory are matched; otherwise, the interpretation of Pattern is implementation defined. Only items that match Filter will be returned. The exception Name_Error is propagated if the string given by Directory does not identify an existing directory, or if Pattern does not allow the identification of any possible external file or directory. The exception Use_Error is propagated if the external environment does not support the searching of the directory with the given name (in the absence of Name_Error). 112/3

Discussion: "In turn" means that the calls to the subprogram designated by Process are not made in parallel; they can be made in any order but must be in sequence. 112.a/2

```
function Simple_Name (Directory_Entry : in Directory_Entry_Type)
   return String;
```
113/2

Returns the simple external name of the external file (including directories) represented by Directory_Entry. The format of the name returned is implementation defined. The exception Status_Error is propagated if Directory_Entry is invalid. 114/2

115/2
```
function Full_Name (Directory_Entry : in Directory_Entry_Type)
     return String;
```

116/2 Returns the full external name of the external file (including directories) represented by Directory_Entry. The format of the name returned is implementation defined. The exception Status_Error is propagated if Directory_Entry is invalid.

117/2
```
function Kind (Directory_Entry : in Directory_Entry_Type)
     return File_Kind;
```

118/2 Returns the kind of external file represented by Directory_Entry. The exception Status_Error is propagated if Directory_Entry is invalid.

119/2
```
function Size (Directory_Entry : in Directory_Entry_Type)
     return File_Size;
```

120/2 Returns the size of the external file represented by Directory_Entry. The size of an external file is the number of stream elements contained in the file. If the external file represented by Directory_Entry is not an ordinary file, the result is implementation defined. The exception Status_Error is propagated if Directory_Entry is invalid. The exception Constraint_Error is propagated if the file size is not a value of type File_Size.

121/2
```
function Modification_Time (Directory_Entry : in Directory_Entry_Type)
     return Ada.Calendar.Time;
```

122/2 Returns the time that the external file represented by Directory_Entry was most recently modified. If the external file represented by Directory_Entry is not an ordinary file, the result is implementation defined. The exception Status_Error is propagated if Directory_Entry is invalid. The exception Use_Error is propagated if the external environment does not support reading the modification time of the file represented by Directory_Entry.

Implementation Requirements

123/2 For Copy_File, if Source_Name identifies an existing external ordinary file created by a predefined Ada input-output package, and Target_Name and Form can be used in the Create operation of that input-output package with mode Out_File without raising an exception, then Copy_File shall not propagate Use_Error.

123.a/2 **Discussion:** This means that Copy_File will copy any file that the Ada programmer could copy (by writing some possibly complicated Ada code).

Implementation Advice

124/2 If other information about a file (such as the owner or creation date) is available in a directory entry, the implementation should provide functions in a child package Directories.Information to retrieve it.

124.a/2 **Implementation Advice:** Package Directories.Information should be provided to retrieve other information about a file.

124.b/2 **Implementation Note:** For Windows®, Directories.Information should contain at least the following routines:

124.c/5
```
{AI12-0302-1} package Ada.Directories.Information
   with Global => in out synchronized is
     -- System-specific directory information.
     -- Version for the Microsoft® Windows® operating system.
```

124.d/2
```
     function Creation_Time (Name : in String) return Ada.Calendar.Time;
```

124.e/2
```
     function Last_Access_Time (Name : in String) return Ada.Calendar.Time;
```

124.f/2
```
     function Is_Read_Only (Name : in String) return Boolean;
```

124.g/2
```
     function Needs_Archiving (Name : in String) return Boolean;
          -- This generally means that the file needs to be backed up.
          -- The flag is only cleared by backup programs.
```

124.h/2
```
     function Is_Compressed (Name : in String) return Boolean;
```

```
      function Is_Encrypted (Name : in String) return Boolean;                                    124.i/2
      function Is_Hidden (Name : in String) return Boolean;                                       124.j/2
      function Is_System (Name : in String) return Boolean;                                       124.k/2
      function Is_Offline (Name : in String) return Boolean;                                      124.l/2
      function Is_Temporary (Name : in String) return Boolean;                                    124.m/2
      function Is_Sparse (Name : in String) return Boolean;                                       124.n/2
      function Is_Not_Indexed (Name : in String) return Boolean;                                  124.o/2
      function Creation_Time (Directory_Entry : in Directory_Entry_Type)                          124.p/2
           return Ada.Calendar.Time;
      function Last_Access_Time (Directory_Entry : in Directory_Entry_Type)                       124.q/2
           return Ada.Calendar.Time;
      function Is_Read_Only (Directory_Entry : in Directory_Entry_Type) return Boolean;           124.r/2
      function Needs_Archiving (Directory_Entry : in Directory_Entry_Type) return                 124.s/2
Boolean;
          -- This generally means that the file needs to be backed up.
          -- The flag is only cleared by backup programs.
      function Is_Compressed (Directory_Entry : in Directory_Entry_Type) return Boolean;           124.t/2
      function Is_Encrypted (Directory_Entry : in Directory_Entry_Type) return Boolean;           124.u/2
      function Is_Hidden (Directory_Entry : in Directory_Entry_Type) return Boolean;              124.v/2
      function Is_System (Directory_Entry : in Directory_Entry_Type) return Boolean;              124.w/2
      function Is_Offline (Directory_Entry : in Directory_Entry_Type) return Boolean;             124.x/2
      function Is_Temporary (Directory_Entry : in Directory_Entry_Type) return Boolean;           124.y/2
      function Is_Sparse (Directory_Entry : in Directory_Entry_Type) return Boolean;              124.z/2
      function Is_Not_Indexed (Directory_Entry : in Directory_Entry_Type) return                  124.aa/2
Boolean;
      -- Additional implementation-defined subprograms allowed here.                             124.bb/2
end Ada.Directories.Information;
```

For Unix-like systems (Unix, POSIX, Linux, etc.), Directories.Information should contain at least the following routines: 124.cc/2

```
{AI12-0302-1} package Ada.Directories.Information                                                 124.dd/5
   with Global => in out synchronized is
   -- System-specific directory information.
   -- Unix and similar systems version.
      function Last_Access_Time (Name : in String) return Ada.Calendar.Time;                      124.ee/2
      function Last_Status_Change_Time (Name : in String) return Ada.Calendar.Time;               124.ff/2
      type Permission is                                                                          124.gg/2
        (Others_Execute, Others_Write, Others_Read,
         Group_Execute,  Group_Write,  Group_Read,
         Owner_Execute,  Owner_Write,  Owner_Read,
         Set_Group_ID,   Set_User_ID);
      type Permission_Set_Type is array (Permission) of Boolean;                                  124.hh/2
      function Permission_Set (Name : in String) return Permission_Set_Type;                      124.ii/2
      function Owner (Name : in String) return String;                                            124.jj/2
          -- Returns the image of the User_Id. If a definition of User_Id
          -- is available, an implementation-defined version of Owner
          -- returning User_Id should also be defined.
{AI05-0005-1}     function Group (Name : in String) return String;                              124.kk/3
          -- Returns the image of the Group_Id. If a definition of Group_Id
          -- is available, an implementation-defined version of Group
          -- returning Group_Id should also be defined.
      function Is_Block_Special_File (Name : in String) return Boolean;                           124.ll/2
      function Is_Character_Special_File (Name : in String) return Boolean;                       124.mm/2
      function Is_FIFO (Name : in String) return Boolean;                                         124.nn/2
      function Is_Symbolic_Link (Name : in String) return Boolean;                                124.oo/2
      function Is_Socket (Name : in String) return Boolean;                                       124.pp/2
      function Last_Access_Time (Directory_Entry : in Directory_Entry_Type)                       124.qq/2
         return Ada.Calendar.Time;
      function Last_Status_Change_Time (Directory_Entry : in Directory_Entry_Type)                124.rr/2
         return Ada.Calendar.Time;
```

124.ss/2
```
      function Permission_Set (Directory_Entry : in Directory_Entry_Type)
         return Permission_Set_Type;
```
124.tt/2
```
      function Owner (Directory_Entry : in Directory_Entry_Type) return String;
         -- See Owner above.
```
124.uu/2
```
      function Group (Directory_Entry : in Directory_Entry_Type) return String;
         -- See Group above.
```
124.vv/2
```
      function Is_Block_Special_File (Directory_Entry : in Directory_Entry_Type)
         return Boolean;
```
124.ww/2
```
      function Is_Character_Special_File (Directory_Entry : in Directory_Entry_Type)
         return Boolean;
```
124.xx/2
```
      function Is_FIFO (Directory_Entry : in Directory_Entry_Type) return Boolean;
```
124.yy/2
```
      function Is_Symbolic_Link (Directory_Entry : in Directory_Entry_Type)
         return Boolean;
```
124.zz/2
```
      function Is_Socket (Directory_Entry : in Directory_Entry_Type) return Boolean;
```
124.aaa/2
```
      -- Additional implementation-defined subprograms allowed here.
   end Ada.Directories.Information;
```

124.bbb/2 We give these definitions to give guidance so that every implementation for a given target is not unnecessarily different. Implementers are encouraged to make packages for other targets as similar to these as possible.

125/5 {*AI05-0231-1*} {*AI12-0439-1*} Start_Search and Search should raise Name_Error if Pattern is malformed, but not if it can represent a file in the directory but does not actually do so.

125.a/3 **Implementation Advice:** Directories.Start_Search and Directories.Search should raise Name_Error for malformed patterns.

126/2 Rename should be supported at least when both New_Name and Old_Name are simple names and New_Name does not identify an existing external file.

126.a/2 **Implementation Advice:** Directories.Rename should be supported at least when both New_Name and Old_Name are simple names and New_Name does not identify an existing external file.

126.b/2 **Discussion:** "Supported" includes raising an exception if either name is malformed, the file to rename doesn't exist, insufficient permission for the operation exists, or similar problems. But this advice requires implementations to document what they do, and tells implementers that simply raising Use_Error isn't acceptable.

127/5 NOTE 1 {*AI12-0442-1*} The operations Containing_Directory, Full_Name, Simple_Name, Base_Name, Extension, and Compose operate on file names, not external files. The files identified by these operations do not necessarily exist. Name_Error is raised only if the file name is malformed and cannot possibly identify a file. Of these operations, only the result of Full_Name depends on the current default directory; the result of the others depends only on their parameters.

128/2 NOTE 2 Using access types, values of Search_Type and Directory_Entry_Type can be saved and queried later. However, another task or application can modify or delete the file represented by a Directory_Entry_Type value or the directory represented by a Search_Type value; such a value can only give the information valid at the time it is created. Therefore, long-term storage of these values is not recommended.

129/2 NOTE 3 If the target system does not support directories inside of directories, then Kind will never return Directory and Containing_Directory will always raise Use_Error.

130/2 NOTE 4 If the target system does not support creation or deletion of directories, then Create_Directory, Create_Path, Delete_Directory, and Delete_Tree will always propagate Use_Error.

131/5 NOTE 5 {*AI12-0442-1*} {*AI12-0447-1*} To move a file or directory to a different location, use Rename. Most target systems will allow renaming of files from one directory to another. If the target file or directory can already exist, it should be deleted first.

131.a/2 **Discussion:** While Rename is only guaranteed to work for name changes within a single directory, its unlikely that implementers would purposely prevent functionality present in the underlying system from working. To move a file totally portably, it's necessary to handle failure of the Rename and fall back to Copy_File and Delete:

131.b
```
begin
   Rename (Source, Target);
exception
   when Use_Error =>
      Copy_File (Source, Target);
      Delete (Source);
end;
```

Extensions to Ada 95

131.c/2 {*AI95-00248-01*} Package Ada.Directories is new.

Inconsistencies With Ada 2005

{*AI05-0231-1*} **Correction**: Clarified when and which exceptions are raised for Start_Search, Search, Delete_Directory, and Rename. If an implementation followed the original incorrect wording, it might raise Use_Error instead of Name_Error for Start_Search and Search, Name_Error instead of Use_Error for Rename, and might have deleted a nonempty directory instead of raising Use_Error for Delete_Directory. The first two cases are very unlikely to matter in practice, and it unlikely that an implementation would have followed the latter implementation strategy, as it would be more work and would make Delete_Directory identical to Delete_Tree (which is obvious nonsense). 131.d/3

Incompatibilities With Ada 2005

{*AI05-0049-1*} A new enumeration type Name_Case_Kind and a new function Name_Case_Equivalence is added to Directories. If Directories is referenced in a use_clause, and an entity *E* with a defining_identifier of one of the new entities is defined in a package that is also referenced in a use_clause, the entity *E* may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur. 131.e/3

Wording Changes from Ada 2005

{*AI05-0271-1*} **Correction:** We now explicitly say that the behavior of Create_Path and Copy_File is unspecified when Use_Error is raised. Nothing has changed here, as the behavior was (implicitly) unspecified in the 2007 Amendment. 131.f/3

Wording Changes from Ada 2012

{*AI12-0337-1*} {*AI12-0433-1*} **Correction:** Clarified the meaning of Simple_Name in the case that the parameter is a root directory. This was not previously described. 131.g/5

A.16.1 The Package Directories.Hierarchical_File_Names

{*AI05-0049-1*} The library package Directories.Hierarchical_File_Names is an optional package providing operations for file name construction and decomposition for targets with hierarchical file naming. 1/3

Static Semantics

{*AI05-0049-1*} If provided, the library package Directories.Hierarchical_File_Names has the following declaration: 2/3

```
{AI12-0241-1} {AI12-0302-1} package Ada.Directories.Hierarchical_File_Names                    3/5
   with Nonblocking, Global => in out synchronized is

   function Is_Simple_Name (Name : in String) return Boolean;                                  4/3

   function Is_Root_Directory_Name (Name : in String) return Boolean;                          5/3

   function Is_Parent_Directory_Name (Name : in String) return Boolean;                        6/3

   function Is_Current_Directory_Name (Name : in String) return Boolean;                       7/3

   function Is_Full_Name (Name : in String) return Boolean;                                    8/3

   function Is_Relative_Name (Name : in String) return Boolean;                                9/3

   function Simple_Name (Name : in String) return String                                       10/3
      renames Ada.Directories.Simple_Name;

   function Containing_Directory (Name : in String) return String                              11/3
      renames Ada.Directories.Containing_Directory;

   function Initial_Directory (Name : in String) return String;                                12/3

   function Relative_Name (Name : in String) return String;                                    13/3

   function Compose (Directory      : in String := "";                                         14/3
                     Relative_Name  : in String;
                     Extension      : in String := "") return String;

end Ada.Directories.Hierarchical_File_Names;                                                   15/3
```

{*AI05-0049-1*} {*AI05-0269-1*} In addition to the operations provided in package Directories.Hierarchical_File_Names, the operations in package Directories can be used with hierarchical 16/3

file names. In particular, functions Full_Name, Base_Name, and Extension provide additional capabilities for hierarchical file names.

17/3 `function Is_Simple_Name (Name : in String) return Boolean;`

18/3 Returns True if Name is a simple name, and returns False otherwise.

18.a/5 **Ramification:** {*AI12-0337-1*} Root directories are considered simple names, so this function will return True if Name represents a root. Use Is_Root_Directory if it is necessary to distinguish roots and other simple names.

19/3 `function Is_Root_Directory_Name (Name : in String) return Boolean;`

20/3 Returns True if Name is syntactically a root (a directory that cannot be decomposed further), and returns False otherwise.

21/3 `function Is_Parent_Directory_Name (Name : in String) return Boolean;`

22/3 Returns True if Name can be used to indicate symbolically the parent directory of any directory, and returns False otherwise.

22.a/3 **Implementation Note:** Is_Parent_Directory_Name returns True if and only if Name is ".." for both Unix and Windows®.

23/3 `function Is_Current_Directory_Name (Name : in String) return Boolean;`

24/3 Returns True if Name can be used to indicate symbolically the directory itself for any directory, and returns False otherwise.

24.a/3 **Implementation Note:** Is_Current_Directory_Name returns True if and only if Name is "." for both Unix and Windows®.

25/3 `function Is_Full_Name (Name : in String) return Boolean;`

26/3 Returns True if the leftmost directory part of Name is a root, and returns False otherwise.

27/3 `function Is_Relative_Name (Name : in String) return Boolean;`

28/3 {*AI05-0049-1*} {*AI05-0269-1*} Returns True if Name allows the identification of an external file (including directories and special files) but is not a full name, and returns False otherwise.

28.a/5 **Ramification:** {*AI12-0337-1*} Relative names include simple names other than root directories as a special case. This function returns False if the syntax of the name is incorrect.

29/3 `function Initial_Directory (Name : in String) return String;`

30/3 {*AI05-0049-1*} {*AI05-0248-1*} Returns the leftmost directory part in Name. [That is, it returns a root directory name (for a full name), or one of a parent directory name, a current directory name, or a simple name (for a relative name).] The exception Name_Error is propagated if the string given as Name does not allow the identification of an external file (including directories and special files).

31/3 `function Relative_Name (Name : in String) return String;`

32/3 Returns the entire file name except the Initial_Directory portion. The exception Name_Error is propagated if the string given as Name does not allow the identification of an external file (including directories and special files), or if Name has a single part (this includes if any of Is_Simple_Name, Is_Root_Directory_Name, Is_Parent_Directory_Name, or Is_Current_Directory_Name are True).

32.a/3 **Ramification:** The result might be a simple name.

33/3
```
function Compose (Directory      : in String := "";
                  Relative_Name  : in String;
                  Extension      : in String := "") return String;
```

34/3 Returns the name of the external file with the specified Directory, Relative_Name, and Extension. The exception Name_Error is propagated if the string given as Directory is not the null string and does not allow the identification of a directory, or if Is_Relative_Name (Relative_Name) is False,

or if the string given as Extension is not the null string and is not a possible extension, or if Extension is not the null string and Simple_Name (Relative_Name) is not a base name.

The result of Compose is a full name if Is_Full_Name (Directory) is True; result is a relative name otherwise. 35/3

Ramification: Name_Error is raised by Compose if Directory is not the null string, and both Is_Full_Name and Is_Relative_Name return False. 35.a/3

Discussion: A common security problem is to include a parent directory name in the middle of a file name; this is often used to navigate outside of an intended root directory. We considered attempting to prevent that case by having Compose detect it and raise an exception. But the extra rules necessary were more confusing than helpful. 35.b/3

{*AI12-0337-1*} We can say more about the details of these operations by adopting the notation of a subscript to specify how many path fragments a particular result has. Then, we can abbreviate "Full Name" as "Full" and "Relative Name" as "Rel". In this notation, Unix file name "a/b" is a Rel(2), "../c/d" is a Rel(3), and "/a/b" is a Full(2). Rel(1) is equivalent to a simple name that is not a root; thus we don't have to describe that separately. 35.c/5

In this notation, 35.d/3

35.e/3

```
For N>1,
Containing_Directory(Rel(N)) = Leftmost Rel(N-1),
Containing_Directory(Full(N)) = Leftmost Full(N-1),
Else if N = 1, raise Use_Error.
```

{*AI12-0337-1*} Similarly, 35.f/3

```
For N>1,                                                          35.g/3
Relative_Name(Rel(N)) = Rightmost Rel(N-1),
Relative_Name(Full(N)) = Rightmost Full(N-1),
Else if N = 1, raise Name_Error.
```

Finally, for Compose (ignoring the extension here): 35.h/3

```
Compose (Directory => Full(N), Relative_Name => Rel(M)) => Full(N+M)   35.i/3
Compose (Directory => Rel(N), Relative_Name => Rel(M)) => Rel(N+M)
Name_Error if Relative_Name is a Full(M).
```

We didn't try to write wording to reflect these details of these functions. 35.j/3

Implementation Advice

{*AI05-0049-1*} Directories.Hierarchical_File_Names should be provided for systems with hierarchical file naming, and should not be provided on other systems. 36/3

Implementation Advice: Directories.Hierarchical_File_Names should be provided for systems with hierarchical file naming, and should not be provided on other systems. 36.a/3

Implementation Note: This package should be provided when targeting Microsoft® Windows®, Unix, Linux, and most Unix-like systems. 36.b/3

NOTE 1 {*AI05-0049-1*} {*AI12-0442-1*} These operations operate on file names, not external files. The files identified by these operations do not necessarily exist. Name_Error is raised only as specified or if the file name is malformed and cannot possibly identify a file. The result of these operations depends only on their parameters. 37/5

NOTE 2 {*AI05-0049-1*} Containing_Directory raises Use_Error if Name does not have a containing directory, including when any of Is_Simple_Name, Is_Root_Directory_Name, Is_Parent_Directory_Name, or Is_Current_Directory_Name are True. 38/3

Ramification: In particular, the default directory is not used to find the containing directory either when Is_Parent_Directory_Name or Is_Current_Directory_Name is True. As noted above, these functions operate purely on the syntax of the file names and do not attempt to interpret them. If interpretation is needed, Directories.Full_Name can be to expand any shorthands used before calling Containing_Directory. 38.a/3

Extensions to Ada 2005

{*AI05-0049-1*} Package Ada.Directories.Hierarchical_File_Names is new. 38.b/3

A.16.2 The Packages Wide_Directories and Wide_Wide_Directories

1/5 {*AI12-0021-1*} The packages Wide_Directories and Wide_Wide_Directories provide operations for manipulating files and directories, and their names.

Static Semantics

2/5 {*AI12-0021-1*} The specification of package Wide_Directories is the same as for Directories (including its optional child packages Information and Hierarchical_File_Names), except that each occurrence of String is replaced by Wide_String.

3/5 {*AI12-0021-1*} The specification of package Wide_Wide_Directories is the same as for Directories (including its optional child packages Information and Hierarchical_File_Names), except that each occurrence of String is replaced by Wide_Wide_String.

Extensions to Ada 2012

3.a/5 {*AI12-0021-1*} These six packages are new.

A.17 The Package Environment_Variables

1/2 {*AI95-00370-01*} The package Environment_Variables allows a program to read or modify environment variables. Environment variables are name-value pairs, where both the name and value are strings. The definition of what constitutes an *environment variable*, and the meaning of the name and value, are implementation defined.

1.a/2 **Implementation defined:** The definition and meaning of an environment variable.

Static Semantics

2/2 {*AI95-00370-01*} The library package Environment_Variables has the following declaration:

3/5
```
{AI12-0241-1} {AI12-0302-1} package Ada.Environment_Variables
   with Preelaborate, Nonblocking, Global => in out synchronized is
```

4/2
```
   function Value (Name : in String) return String;
```

4.1/3
```
{AI05-0285-1}    function Value (Name : in String; Default : in String) return
String;
```

5/2
```
   function Exists (Name : in String) return Boolean;
```

6/2
```
   procedure Set (Name : in String; Value : in String);
```

7/2
```
   procedure Clear (Name : in String);
   procedure Clear;
```

8/5
```
{AI05-0248-1} {AI12-0286-1}    procedure Iterate
      (Process : not null access procedure (Name, Value : in String))
      with Allows_Exit;
```

9/2
```
end Ada.Environment_Variables;
```

10/2
```
function Value (Name : in String) return String;
```

11/2 {*AI95-00370-01*} If the external execution environment supports environment variables, then Value returns the value of the environment variable with the given name. If no environment variable with the given name exists, then Constraint_Error is propagated. If the execution environment does not support environment variables, then Program_Error is propagated.

```
function Value (Name : in String; Default : in String) return String;
```
11.1/3

{*AI05-0285-1*} If the external execution environment supports environment variables and an environment variable with the given name currently exists, then Value returns its value; otherwise, it returns Default. 11.2/3

```
function Exists (Name : in String) return Boolean;
```
12/2

{*AI95-00370-01*} {*AI05-0264-1*} If the external execution environment supports environment variables and an environment variable with the given name currently exists, then Exists returns True; otherwise, it returns False. 13/3

```
procedure Set (Name : in String; Value : in String);
```
14/2

{*AI95-00370-01*} {*AI05-0264-1*} If the external execution environment supports environment variables, then Set first clears any existing environment variable with the given name, and then defines a single new environment variable with the given name and value. Otherwise, Program_Error is propagated. 15/3

If implementation-defined circumstances prohibit the definition of an environment variable with the given name and value, then Constraint_Error is propagated. 16/2

Implementation defined: The circumstances where an environment variable cannot be defined. 16.a/2

It is implementation defined whether there exist values for which the call Set(Name, Value) has the same effect as Clear (Name). 17/2

Implementation defined: Environment names for which Set has the effect of Clear. 17.a/2

```
procedure Clear (Name : in String);
```
18/2

{*AI95-00370-01*} {*AI05-0264-1*} {*AI05-0269-1*} If the external execution environment supports environment variables, then Clear deletes all existing environment variables with the given name. Otherwise, Program_Error is propagated. 19/3

```
procedure Clear;
```
20/2

{*AI95-00370-01*} {*AI05-0264-1*} If the external execution environment supports environment variables, then Clear deletes all existing environment variables. Otherwise, Program_Error is propagated. 21/3

```
{AI05-0248-1} {AI12-0286-1} procedure Iterate
   (Process : not null access procedure (Name, Value : in String))
      with Allows_Exit;
```
22/5

{*AI95-00370-01*} {*AI05-0264-1*} If the external execution environment supports environment variables, then Iterate calls the subprogram designated by Process for each existing environment variable, passing the name and value of that environment variable. Otherwise, Program_Error is propagated. 23/3

If several environment variables exist that have the same name, Process is called once for each such variable. 24/2

Bounded (Run-Time) Errors

{*AI95-00370-01*} It is a bounded error to call Value if more than one environment variable exists with the given name; the possible outcomes are that: 25/2

- one of the values is returned, and that same value is returned in subsequent calls in the absence of changes to the environment; or 26/2
- Program_Error is propagated. 27/2

Erroneous Execution

28/2 {*AI95-00370-01*} Making calls to the procedures Set or Clear concurrently with calls to any subprogram of package Environment_Variables, or to any instantiation of Iterate, results in erroneous execution.

29/2 Making calls to the procedures Set or Clear in the actual subprogram corresponding to the Process parameter of Iterate results in erroneous execution.

Documentation Requirements

30/2 {*AI95-00370-01*} An implementation shall document how the operations of this package behave if environment variables are changed by external mechanisms (for instance, calling operating system services).

30.a/2 **Documentation Requirement:** The behavior of package Environment_Variables when environment variables are changed by external mechanisms.

Implementation Permissions

31/2 {*AI95-00370-01*} An implementation running on a system that does not support environment variables is permitted to define the operations of package Environment_Variables with the semantics corresponding to the case where the external execution environment does support environment variables. In this case, it shall provide a mechanism to initialize a nonempty set of environment variables prior to the execution of a partition.

Implementation Advice

32/2 {*AI95-00370-01*} If the execution environment supports subprocesses, the currently defined environment variables should be used to initialize the environment variables of a subprocess.

32.a/2 **Implementation Advice:** If the execution environment supports subprocesses, the current environment variables should be used to initialize the environment variables of a subprocess.

33/2 Changes to the environment variables made outside the control of this package should be reflected immediately in the effect of the operations of this package. Changes to the environment variables made using this package should be reflected immediately in the external execution environment. This package should not perform any buffering of the environment variables.

33.a/2 **Implementation Advice:** Changes to the environment variables made outside the control of Environment_Variables should be reflected immediately.

Extensions to Ada 95

33.b/2 {*AI95-00370-01*} Package Environment_Variables is new.

Incompatibilities With Ada 2005

33.c/3 {*AI05-0285-1*} A new overloaded function Value is added to Environment_Variables. If Environment_Variables is referenced in a use_clause, and an entity *E* with the name Value is defined in a package that is also referenced in a use_clause, the entity *E* may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur.

A.17.1 The Packages Wide_Environment_Variables and Wide_Wide_Environment_Variables

1/5 {*AI12-0021-1*} The packages Wide_Environment_Variables and Wide_Wide_Environment_Variables allow a program to read or modify environment variables.

Static Semantics

{*AI12-0021-1*} The specification of package Wide_Environment_Variables is the same as for Environment_Variables, except that each occurrence of String is replaced by Wide_String. 2/5

{*AI12-0021-1*} The specification of package Wide_Wide_Environment_Variables is the same as for Environment_Variables, except that each occurrence of String is replaced by Wide_Wide_String. 3/5

Extensions to Ada 2012

{*AI12-0021-1*} These packages are new. 3.a/5

A.18 Containers

{*AI95-00302-03*} This clause presents the specifications of the package Containers and several child packages, which provide facilities for storing collections of elements. 1/2

Term entry: container — structured object that represents a collection of elements all of the same (potentially class-wide) type, such as a vector or a tree 1.a/5
Note: Several predefined container types are provided by the children of package Ada.Containers (see A.18.1).

{*AI95-00302-03*} {*AI12-0196-1*} {*AI12-0416-1*} A variety of sequence and associative containers are provided. Each container package defines a *cursor* type as well as a container type. A cursor is a reference to an element within a container. Many operations on cursors are common to all of the containers. A cursor referencing an element in a container is considered to be overlapping only with the element itself. 2/5

Reason: {*AI12-0005-1*} {*AI12-0196-1*} The last sentence is intended to clarify that operations that just use a cursor do not interfere if the cursor objects designated different elements of the container in terms of the concurrent call rules of Annex A. 2.a/5

Ramification: {*AI12-0196-1*} A cursor is not considered to overlap with other elements of the associated container, thus parallel operations involving a set of cursors each operating on mutually exclusive sets of elements from the same container are expected to work. 2.b/5

Discussion: {*AI12-0416-1*} We use the term “container” alone when it is clear from context what kind of entity (package, type, or object) that we are talking about. Otherwise, we use “container package”, “container type”, or “container object”. Note that "container type" is defined in 4.3.5 for a different usage; in all of A.18 we mean “container type” to be one of the primary types declared in the child packages of package Containers, such as Vector, List, or Map. 2.c/5

{*AI12-0111-1*} {*AI12-0439-1*} Some operations of the language-defined child units of Ada.Containers have access-to-subprogram parameters. To ensure such operations are well-defined, they guard against certain actions by the designated subprogram. An action on a container that can add or remove an element is considered to *tamper with cursors*, and these are prohibited during all such operations. An action on a container that can replace an element with one of a different size is considered to *tamper with elements*, and these are prohibited during certain of such operations. The details of the specific actions that are considered to tamper with cursors or elements are defined for each child unit of Ada.Containers. 2.1/5

{*AI12-0111-1*} Several of the language-defined child units of Ada.Containers include a nested package named Stable, which provides a view of a container that prohibits any operations that would tamper with elements. By using a Stable view for manipulating a container, the number of tampering checks performed while performing the operations can be reduced. The details of the Stable subpackage are defined separately for each child unit of Ada.Containers that includes such a nested package. 2.2/5

{*AI95-00302-03*} Within this clause we provide Implementation Advice for the desired average or worst case time complexity of certain operations on a container. This advice is expressed using the Landau symbol *O*(X). Presuming f is some function of a length parameter N and t(N) is the time the operation takes (on average or worst case, as specified) for the length N, a complexity of *O*(f(N)) means that there exists a finite A such that for any N, t(N)/f(N) < A. 3/2

3.a/2 **Discussion:** Of course, an implementation can do better than a specified *O*(f(N)): for example, *O*(1) meets the requirements for *O*(log N).

3.b/2 This concept seems to have as many names as there are authors. We used “Landau symbol” because that's what our reference does. But we'd also seen this referred as big-O notation (sometimes written as *big-oh*), and as Bachmann notation. Whatever the name, it always has the above definition.

4/2 If the advice suggests that the complexity should be less than *O*(f(N)), then for any arbitrarily small positive real D, there should exist a positive integer M such that for all N > M, t(N)/f(N) < D.

5/5 {*AI05-0001-1*} {*AI05-0044-1*} {*AI12-0416-1*} When a formal function is used to provide an ordering for a container, it is generally required to define a strict weak ordering. A function "<" defines a *strict weak ordering* if it is irreflexive, asymmetric, transitive, and in addition, if $x < y$ for any values x and y, then for all other values z, ($x < z$) or ($z < y$). Elements are in a *smallest first* order using such an operator if, for every element y with a predecessor x in the order, ($y < x$) is false.

5.a.1/5 **Reason:** {*AI12-0416-1*} Given a "<" operator that provides a strict weak ordering, knowing that ($y < x$) is false is enough to know that ($x <= y$) is true. For a strict weak ordering, ($x = y$) when both ($x < y$) and ($y < x$) are false. Therefore, it is not necessary to use the "=" operator or test ($x < y$). We only need to discuss adjacent elements since a strict weak ordering is transitive.

Language Design Principles

5.a/3 {*AI95-00302-03*} {*AI05-0299-1*} This subclause provides a number of useful containers for Ada. Only the most useful containers are provided. Ones that are relatively easy to code, redundant, or rarely used are omitted from this set, even if they are generally included in containers libraries.

5.b/2 The containers packages are modeled on the Standard Template Library (STL), an algorithms and data structure library popularized by Alexander Stepanov, and included in the C++ standard library. The structure and terminology differ from the STL where that better maps to common Ada usage. For instance, what the STL calls “iterators” are called “cursors” here.

5.c/2 The following major nonlimited containers are provided:

5.d/2 - (Expandable) Vectors of any nonlimited type;

5.e/2 - Doubly-linked Lists of any nonlimited type;

5.f/2 - Hashed Maps keyed by any nonlimited hashable type, and containing any nonlimited type;

5.g/2 - Ordered Maps keyed by any nonlimited ordered type, and containing any nonlimited type;

5.h/3 - {*AI05-0136-1*} Hashed Sets of any nonlimited hashable type;

5.i/3 - {*AI05-0136-1*} Ordered Sets of any nonlimited ordered type;

5.i.1/3 - {*AI05-0136-1*} Multiway Trees of any nonlimited type;

5.i.2/3 - {*AI05-0069-1*} Holders of any (indefinite) nonlimited type;

5.i.3/3 - {*AI05-0159-1*} Synchronized queues of any definite nonlimited type; and

5.i.4/3 - {*AI05-0159-1*} Priority queues of any definite nonlimited type.

5.j/3 {*AI05-0001-1*} Separate versions for definite and indefinite element types are provided, as those for definite types can be implemented more efficiently. Similarly, a separate bounded version is provided in order to give more predictable memory usage.

5.k/2 Each container includes a cursor, which is a reference to an element within a container. Cursors generally remain valid as long as the container exists and the element referenced is not deleted. Many operations on cursors are common to all of the containers. This makes it possible to write generic algorithms that work on any kind of container.

5.l/2 The containers packages are structured so that additional packages can be added in the future. Indeed, we hope that these packages provide the basis for a more extensive secondary standard for containers.

5.m/2 If containers with similar functionality (but different performance characteristics) are provided (by the implementation or by a secondary standard), we suggest that a prefix be used to identify the class of the functionality: "Ada.Containers.Bounded_Sets" (for a set with a maximum number of elements); "Ada.Containers.Protected_Maps" (for a map which can be accessed by multiple tasks at one time); "Ada.Containers.Persistent_Vectors" (for a persistent vector which continues to exist between executions of a program) and so on.

5.n/2 Note that the language already includes several requirements that are important to the use of containers. These include:

5.o/5 - {*AI12-0196-1*} Library packages must allow concurrent calls – multiple tasks can use the packages as long as they operate on separate containers. Thus, it is only necessary for a user to protect a container if a single

container needs to be used by multiple tasks and concurrent calls to operations of the container have overlapping parameters.

- Language-defined types must stream "properly". That means that the stream attributes can be used to implement persistence of containers when necessary, and containers can be passed between partitions of a program. 5.p/2
- Equality of language-defined types must compose “properly”. This means that the version of "=" directly used by users is the same one that will be used in generics and in predefined equality operators of types with components of the containers and/or cursors. This prevents the abstraction from breaking unexpectedly. 5.q/2
- {*AI05-0048-1*} Redispatching is not allowed (unless it is required). That means that overriding a container operation will not change the behavior of any other predefined container operation. This provides a stable base for extensions. 5.q.1/3

{*AI12-0258-1*} If a container's element type is controlled, the point at which the element is finalized will depend on the implementation of the container. For certain kinds of containers, we require finalization behavior based on the canonical implementation of the container (see the Implementation Requirements below). For the "normal" containers, we do not specify precisely where this will happen (it will happen no later than the finalization of the container, of course) in order to give implementations flexibility to cache, block, split , or reusethe nodes of the container. 5.r/5

This paragraph was deleted.{*AI12-0258-1*} 5.s/5

The use of controlled types also brings up the possibility of failure of finalization (and thus deallocation) of an element. This is a “serious bug”, as AI95-179 puts it, so we don't try to specify what happens in that case. The implementation should propagate the exception. 5.t/2

Implementation Note: It is expected that exceptions propagated from these operations do not damage containers. That is, if Storage_Error is propagated because of an allocation failure, or Constraint_Error is propagated by the assignment of elements, the container can continue to be used without further exceptions. The intent is that it should be possible to recover from errors without losing data. We don't try to state this formally in most cases, because it is hard to define precisely what is and is not allowed behavior. 5.u/2

Implementation Note: {*AI12-0005-1*} When this clause says that the behavior of something is unspecified, we really mean that any result of executing Ada code short of erroneous execution is allowed. We do not mean that memory not belonging to the parameters of the operation can be trashed. When we mean to allow erroneous behavior, we specifically say that execution is erroneous. All this means that, if the containers are written in Ada, checks should not be suppressed or removed assuming some behavior of other code, and that the implementation should take care to avoid creating internal dangling accesses by assuming behavior from generic formals that can't be guaranteed. We don't try to say this normatively because it would be fairly complex, and implementers are unlikely to increase their support costs by fielding implementations that are unstable if given buggy hash functions, et al. 5.v/5

Static Semantics

{*AI12-0035-1*} {*AI12-0449-1*} Certain subprograms declared within instances of some of the generic packages presented in this clause are said to *perform indefinite insertion*. These subprograms are those corresponding (in the sense of the copying described in 12.3) to subprograms that have formal parameters of a generic formal indefinite type and that are identified as performing indefinite insertion in the subclause defining the generic package. 6/5

{*AI12-0035-1*} {*AI12-0449-1*} If a subprogram performs indefinite insertion, then certain run-time checks are performed as part of a call to the subprogram; if any of these checks fail, then the resulting exception is propagated to the caller and the container is not modified by the call. These checks are performed for each parameter corresponding (in the sense of the copying described in 12.3) to a parameter in the corresponding generic whose type is a generic formal indefinite type. The checks performed for a given parameter are those checks explicitly specified in 4.8 that would be performed as part of the evaluation of an initialized allocator whose access type is declared immediately within the instance, where: 7/5

- the value of the qualified_expression is that of the parameter; and 8/4
- the designated subtype of the access type is the subtype of the parameter; and 9/4
- finalization of the collection of the access type has started if and only if the finalization of the instance has started. 10/4

10.a/5 **Discussion:** {*AI12-0449-1*} The phrase "explicitly specified" means those checks for which 4.8 includes the phrase "<some exception> is raised if ...". It does not refer, for example, to any checks performed as part of any subtype conversion. In particular, this wording includes the checks described in 4.8 to be performed in the case of a class-wide designated type, and of a designated subtype that has access discriminant parts. These checks are needed to prevent containers from outliving their contained (Element_Type or Key_Type) values.

10.b/4 **Implementation Note:** These rules have a dual purpose. Mainly, we are *requiring* checks needed to prevent dangling references. As a side effect, we are also *allowing* checks needed to permit an implementation of a container generic to make use of access types in a straightforward way. As an example of the second purpose, suppose that an implementation does declare such an access type and suppose further that the finalization of the collection of the access type has started. These rules allow Program_Error to be propagated in this case (as specified in 4.8); this is necessary to allow an all-Ada implementation of these packages.

Implementation Requirements

11/5 {*AI12-0258-1*} For an indefinite container (one whose type is defined in an instance of a child package of Containers whose defining_identifier contains "Indefinite"), each element of the container shall be created when it is inserted into the container and finalized when it is deleted from the container (or when the container object is finalized if the element has not been deleted). For a bounded container (one whose type is defined in an instance of a child package of Containers whose defining_identifier starts with "Bounded") that is not an indefinite container, all of the elements of the capacity of the container shall be created and default initialized when the container object is created; the elements shall be finalized when the container object is finalized. [For other kinds of containers, when elements are created and finalized is unspecified.]

11.a/5 **Ramification:** This allows a user to be able to reason about the behavior of elements that have controlled parts. In most cases, such elements need to be stored in an indefinite container.

11.b/5 **Implementation Note:** If the containers are implemented in Ada, this implies that elements for an indefinite container are allocated individually, and that a bounded container contains an array of elements or other data structure that is initialized for the entire capacity of the container when it is created. There is no such restriction on the implementation of the "normal" containers; these can be handled in any way convenient to the implementation — in particular, node reuse is allowed.

12/5 {*AI12-0112-1*} For an instance *I* of a container package with a container type, the specific type *T* of the object returned from a function that returns an object of an iterator interface, as well as the primitive operations of *T*, shall be nonblocking. The Global aspect specified for *T* and the primitive operations of *T* shall be (**in all, out synchronized**) or a specification that allows access to fewer global objects.

12.a/5 **Implementation Note:** This requires that the traversal and iteration operations of a container do not create, destroy, or assign any objects of a formal type of *I*, nor call any formal subprograms of *I*. Those objects and subprograms might be blocking (depending on the actual parameters). We put similar requirements on the individual traversal operations in the container package definitions.

12.b/5 **Reason:** These requirements allows users to use container iterators inside of parallel constructs, regardless of the actual parameters to the instantiation. If such an iterator allowed blocking, it would be illegal inside of a parallel construct (see 9.5). If such an iterator allowed writing of unsynchronized global objects, it would be illegal when the default conflict checking policy is in effect (see 9.10.1). These requirements include sequential iterators; the iterator does not need to appear in a parallel loop to trigger these requirements.

12.c/5 **Discussion:** We have to give these requirements as a text rule, as there is no place to declare suitable aspects. The specific type of a container iterator is declared by the implementation and is not part of the visible specification (iterator functions just return a value of a class-wide type). The iterator interface itself cannot impose such a requirement since it needs to be able to work with user-defined types that do need to allow blocking. We give this as a global requirement to avoid duplication.

Extensions to Ada 95

12.d/3 {*AI95-00302-03*} {*AI05-0299-1*} This subclause is new. It just provides an introduction to the following subclauses.

Wording Changes from Ada 2005

12.e/3 {*AI05-0044-1*} **Correction:** Added a definition of strict weak ordering.

Extensions to Ada 2012

{*AI12-0196-1*} **Correction:** We now say that a cursor only overlaps with the element it designates, rather than with the whole container. This allows some reading operations to operate on the container in parallel without separate synchronization. 12.f/5

Wording Changes from Ada 2012

{*AI05-0035-1*} **Corrigendum:** Added a definition of "performs indefinite insertion". This is used in other subclauses and any resulting inconsistencies are documented there. 12.g/4

{*AI12-0111-1*} Moved the basic description of tampering checks here, to cut duplication in description of the individual containers. Added a description of stable views of containers. 12.h/5

{*AI12-0112-1*} Added a global requirement that iterators returned from containers are nonblocking if the instance is nonblocking. 12.i/5

{*AI12-0258-1*} **Correction:** Defined when objects are created and finalized for Bounded and Indefinite containers, so that these can be used reliably with controlled element types. This is not incompatible as this behavior was previously unspecified; code depending on specific behavior was wrong. 12.j/5

{*AI12-0005-1*} {*AI12-0416-1*} Added a definition of "smallest first" ordering, so that the behavior of the Sort procedures when elements are equal is well-defined. 12.k/5

A.18.1 The Package Containers

{*AI95-00302-03*} The package Containers is the root of the containers subsystem. 1/2

Static Semantics

{*AI95-00302-03*} The library package Containers has the following declaration: 2/2

```
{AI12-0414-1} package Ada.Containers                                    3/5
   with Pure is

   type Hash_Type is mod implementation-defined;                        4/2

   type Count_Type is range 0 .. implementation-defined;                5/2

{AI05-0001-1}    Capacity_Error : exception;                            5.1/3

end Ada.Containers;                                                     6/2
```

{*AI95-00302-03*} Hash_Type represents the range of the result of a hash function. Count_Type represents the (potential or actual) number of elements of a container. 7/2

Implementation defined: The value of Containers.Hash_Type'Modulus. The value of Containers.Count_Type'Last. 7.a/2

{*AI05-0262-1*} Capacity_Error is raised when the capacity of a container is exceeded. 7.1/3

Implementation Advice

{*AI95-00302-03*} Hash_Type'Modulus should be at least 2**32. Count_Type'Last should be at least 2**31–1. 8/2

Implementation Advice: Containers.Hash_Type'Modulus should be at least 2**32. Containers.Count_Type'Last should be at least 2**31–1. 8.a/2

Discussion: This is not a requirement so that these types can be declared properly on machines with native sizes that are not 32 bits. For instance, a 24-bit target could use 2**24 for Hash_Type'Modulus. 8.b/2

Extensions to Ada 95

{*AI95-00302-03*} The package Containers is new. 8.c/2

Incompatibilities With Ada 2005

{*AI05-0001-1*} Exception Capacity_Error is added to Containers. If Containers is referenced in a use_clause, and an entity with the name Capacity_Error is defined in a package that is also referenced in a use_clause, the entity Capacity_Error may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur. 8.d/3

A.18.2 The Generic Package Containers.Vectors

1/2 The language-defined generic package Containers.Vectors provides private types Vector and Cursor, and a set of operations for each type. A vector container allows insertion and deletion at any position, but it is specifically optimized for insertion and deletion at the high end (the end with the higher index) of the container. A vector container also provides random access to its elements.

2/2 A vector container behaves conceptually as an array that expands as necessary as items are inserted. The *length* of a vector is the number of elements that the vector contains. The *capacity* of a vector is the maximum number of elements that can be inserted into the vector prior to it being automatically expanded.

3/2 Elements in a vector container can be referred to by an index value of a generic formal type. The first element of a vector always has its index value equal to the lower bound of the formal type.

4/2 A vector container may contain *empty elements*. Empty elements do not have a specified value.

4.a/2 **Implementation Note:** Vectors are not intended to be sparse (that is, there are elements at all defined positions). Users are expected to use other containers (like a Map) when they need sparse structures (there is a Note to this effect at the end of this subclause).

4.b/2 The internal array is a conceptual model of a vector. There is no requirement for an implementation to be a single contiguous array.

Static Semantics

5/2 {*AI95-00302-03*} The generic library package Containers.Vectors has the following declaration:

6/5
```
{AI05-0084-1} {AI05-0212-1} {AI12-0112-1} with Ada.Iterator_Interfaces;
generic
   type Index_Type is range <>;
   type Element_Type is private;
   with function "=" (Left, Right : Element_Type)
      return Boolean is <>;
package Ada.Containers.Vectors
   with Preelaborate, Remote_Types,
        Nonblocking, Global => in out synchronized is
```

6.a/5 **Discussion:** {*AI12-0112-1*} For the Global aspect, any side-effects of the actual parameters of an instance are ignored. So Global => **in out synchronized** means that the only global side-effects allowed are associated with the actual generic parameters of the instance or with any synchronized state. Unsynchronized package state is not allowed for any container package, and pure packages do not allow any package state at all (they typically have Global => **null**).

6.b/5 {*AI12-0112-1*} Similarly, when Nonblocking is set to True for a generic unit, it still includes the blocking effects of the actual parameters to the instance. Thus, the only blocking allowed is that associated with the actual generic parameters. If none of the actual paramerters allow blocking, then no operation of the generic instance may block.

7/2
```
   subtype Extended_Index is
      Index_Type'Base range
         Index_Type'First-1 ..
         Index_Type'Min (Index_Type'Base'Last - 1, Index_Type'Last) + 1;
   No_Index : constant Extended_Index := Extended_Index'First;
```

7.a/5 **Ramification:** {*AI12-0112-1*} The base type of a scalar type is always nonblocking and has Global => **null**. Therefore, so long as this type is used in the implementation, whether or not the actual type for Index_Type allows blocking or side-effects does not matter. Therefore, we require that operations that only operate on the container implementation be nonblocking and have Global => **null** regardless of the actual parameters.

```
{AI05-0212-1} {AI12-0111-1} {AI12-0112-1} {AI12-0212-1} {AI12-0339-1} {AI12-0399-1}    8/5

           Preelaborable_Initialization;

{AI12-0399-1}    type Cursor is private                                                  9/5
      with Preelaborable_Initialization;

   Empty_Vector : constant Vector;                                                      10/2

   No_Element : constant Cursor;                                                        11/2

{AI05-0212-1} {AI12-0112-1}    function Has_Element (Position : Cursor) return       11.1/5
Boolean
      with Nonblocking, Global => in all, Use_Formal => null;
```

Discussion: {*AI12-0112-1*} Any operation that takes a cursor but no vector can read the vector associated with the cursor. We only know that there is some object of type Vector. Since we don't have a global specification that describes all objects of a specific type, we have to allow reading any object by specifying **in all**. For such functions, we don't allow writing any object, even those associated with generic formal parameters, thus we also specify Use_Formal => **null**. 11.a/5

```
{AI12-0112-1}    function Has_Element (Container : Vector; Position : Cursor)        11.2/5
      return Boolean
      with Nonblocking, Global => null, Use_Formal => null;
```

Discussion: {*AI12-0112-1*} For operations that do not depend on any of the operations of the generic formal parameters (including those of formal types), we specify that the operation has no side-effects of any kind. This requires specifying that there is no dependence on the generic formal parameters with Use_Formal => **null** in addition to no usual side-effects with **null**. We also specify Nonblocking on such operations in order that the operation never blocks even if some of the actual parameters allow blocking. 11.b/5

```

{*AI95-00302-03*} The actual function for the generic formal function "=" on Element_Type values is expected to define a reflexive and symmetric relationship and return the same result value each time it is called with a particular pair of values. If it behaves in some other manner, the functions defined to use it return an unspecified value. The exact arguments and number of calls of this generic formal function by the functions defined to use it are unspecified. 83/2

Ramification: The “functions defined to use it” are Find, Find_Index, Reverse_Find, Reverse_Find_Index, and "=" for Vectors. This list is a bit too long to give explicitly. 83.a/2

If the actual function for "=" is not symmetric and consistent, the result returned by any of the functions defined to use "=" cannot be predicted. The implementation is not required to protect against "=" raising an exception, or returning random results, or any other “bad” behavior. And it can call "=" in whatever manner makes sense. But note that only the results of the functions defined to use "=" are unspecified; other subprograms are not allowed to break if "=" is bad. 83.b/2

{*AI95-00302-03*} The type Vector is used to represent vectors. The type Vector needs finalization (see 7.6). 84/2

{*AI95-00302-03*} Empty_Vector represents the empty vector object. It has a length of 0. If an object of type Vector is not otherwise initialized, it is initialized to the same value as Empty_Vector. 85/2

{*AI95-00302-03*} No_Element represents a cursor that designates no element. If an object of type Cursor is not otherwise initialized, it is initialized to the same value as No_Element. 86/2

{*AI95-00302-03*} {*AI12-0434-1*} The primitive "=" operator for type Cursor returns True if both cursors are No_Element, or designate the same element in the same container. 87/5

To be honest: {*AI12-0434-1*} “The primitive "=" operator” is the one with two parameters of type Cursor which returns Boolean. We're not talking about some other (hidden) primitive function named "=". 87.a/5

88/2 {*AI95-00302-03*} Execution of the default implementation of the Input, Output, Read, or Write attribute of type Cursor raises Program_Error.

88.a/2 **Reason:** A cursor will probably be implemented in terms of one or more access values, and the effects of streaming access values is unspecified. Rather than letting the user stream junk by accident, we mandate that streaming of cursors raise Program_Error by default. The attributes can always be specified if there is a need to support streaming.

88.1/5 {*AI05-0001-1*} {*AI05-0262-1*} {*AI12-0437-1*} Vector'Write for a Vector object *V* writes Length(*V*) elements of the vector to the stream. It may also write additional information about the vector.

88.2/3 {*AI05-0001-1*} {*AI05-0262-1*} Vector'Read reads the representation of a vector from the stream, and assigns to *Item* a vector with the same length and elements as was written by Vector'Write.

88.b/3 **Implementation Note:** The Reference Manual requires streaming of all language-defined nonlimited types (including containers) to "work" (see 13.13.2). In addition, we do not want all of the elements that make up the capacity of the vector streamed, as those beyond the length of the container have undefined contents (and might cause bad things when read back in). This will require a custom stream attribute implementation; the language-defined default implementation will not work (even for a bounded form, as that would most likely stream the entire capacity of the vector). There is a separate requirement that the unbounded and Bounded form use the same streaming representation for the same element type, see A.18.19.

89/2 {*AI95-00302-03*} No_Index represents a position that does not correspond to any element. The subtype Extended_Index includes the indices covered by Index_Type plus the value No_Index and, if it exists, the successor to the Index_Type'Last.

89.a/2 **Discussion:** We require the existence of Index_Type'First – 1, so that No_Index and Last_Index of an empty vector is well-defined. We don't require the existence of Index_Type'Last + 1, as it is only used as the position of insertions (and needs to be allowed only when inserting an empty vector).

90/5 {*AI95-00302-03*} {*AI12-0111-1*} {*AI12-0112-1*} [Some operations check for “tampering with cursors” of a container because they depend on the set of elements of the container remaining constant, and others check for “tampering with elements” of a container because they depend on elements of the container not being replaced.] When tampering with cursors is *prohibited* for a particular vector object *V*, Program_Error is propagated by the finalization of *V*[, as well as by a call that passes *V* to certain of the operations of this package, as indicated by the precondition of such an operation]. Similarly, when tampering with elements is *prohibited* for *V*, Program_Error is propagated by a call that passes *V* to certain of the other operations of this package, as indicated by the precondition of such an operation.

Paragraphs 91 through 97 are removed as preconditions now describe these rules.

93.a.1/3 **Ramification:** We don't need to explicitly mention assignment_statement, because that finalizes the target object as part of the operation, and finalization of an object is already defined as tampering with cursors.

97.2/5
```
function Has_Element (Position : Cursor) return Boolean
   with Nonblocking, Global => in all, Use_Formal => null;
```

97.3/3 {*AI05-0212-1*} Returns True if Position designates an element, and returns False otherwise.

97.c/3 **To be honest:** {*AI05-0005-1*} {*AI05-0212-1*} This function might not detect cursors that designate deleted elements; such cursors are invalid (see below) and the result of calling Has_Element with an invalid cursor is unspecified (but not erroneous).

97.4/5
```
function Has_Element (Container : Vector; Position : Cursor)
   return Boolean
   with Nonblocking, Global => null, Use_Formal => null;
```

97.5/5 {*AI12-0112-1*} Returns True if Position designates an element in Container, and returns False otherwise.

97.d/5 **Ramification:** If Position is No_Element, Has_Element returns False.

98/2
```
function "=" (Left, Right : Vector) return Boolean;
```

99/3 {*AI95-00302-03*} {*AI05-0264-1*} If Left and Right denote the same vector object, then the function returns True. If Left and Right have different lengths, then the function returns False.

Otherwise, it compares each element in Left to the corresponding element in Right using the generic formal equality operator. If any such comparison returns False, the function returns False; otherwise, it returns True. Any exception raised during evaluation of element equality is propagated.

Implementation Note: This wording describes the canonical semantics. However, the order and number of calls on the formal equality function is unspecified for all of the operations that use it in this package, so an implementation can call it as many or as few times as it needs to get the correct answer. Specifically, there is no requirement to call the formal equality additional times once the answer has been determined. 99.a/2

```
function Tampering_With_Cursors_Prohibited
   (Container : Vector) return Boolean
   with Nonblocking, Global => null, Use_Formal => null;
```
99.1/5

{*AI12-0112-1*} Returns True if tampering with cursors or tampering with elements is currently prohibited for Container, and returns False otherwise. 99.2/5

Reason: {*AI12-0112-1*} Prohibiting tampering with elements also needs to prohibit tampering with cursors, as deleting an element is similar to replacing it. 99.b/5

Implementation Note: {*AI12-0112-1*} Various contracts elsewhere in this specification require that this function be implemented with synchronized data. Moreover, it is possible for tampering to be prohibited by multiple operations (sequentially or in parallel). Therefore, tampering needs to be implemented with an atomic or protected counter. The counter is initialized to zero, and is incremented when tampering is prohibited, and decremented when leaving an area that prohibited tampering. Function Tampering_With_Cursors_Prohibited returns True if the counter is nonzero. (Note that any case where the result is not well-defined for one task is incorrect use of shared variables and would be erroneous by the rules of 9.10, so no special protection is needed to read the counter.) 99.c/5

```
function Tampering_With_Elements_Prohibited
   (Container : Vector) return Boolean
   with Nonblocking, Global => null, Use_Formal => null;
```
99.3/5

{*AI12-0112-1*} Always returns False[, regardless of whether tampering with elements is prohibited]. 99.4/5

Reason: {*AI12-0111-1*} A definite element cannot change size, so we allow operations that tamper with elements even when tampering with elements is prohibited. That's not true for the indefinite containers, which is why this kind of tampering exists. 99.d/5

```
function Maximum_Length return Count_Type
   with Nonblocking, Global => null, Use_Formal => null;
```
99.5/5

{*AI12-0112-1*} Returns the maximum Length of a Vector, based on the index type. 99.6/5

Implementation Note: This is just: 99.e/5

```
Count_Type (Index_Type'Last - Index_Type'First + 1)
```
99.f

but since the inner calculation can overflow or the type conversion can fail, this can't be evaluated in general with an expression function. Note that if this expression raises Constraint_Error, then the result is Count_Type'Last, since the Capacity of a Vector cannot exceed Count_Type'Last. 99.g/5

```
function Empty (Capacity : Count_Type := implementation-defined)
   return Vector
   with Pre  => Capacity <= Maximum_Length
                   or else raise Constraint_Error,
        Post =>
           Capacity (Empty'Result) >= Capacity and then
           not Tampering_With_Elements_Prohibited (Empty'Result) and then
           not Tampering_With_Cursors_Prohibited (Empty'Result) and then
           Length (Empty'Result) = 0;
```
99.7/5

{*AI12-0339-1*} Returns an empty vector. 99.8/5

100/5
```
function To_Vector (Length : Count_Type) return Vector
   with Pre  => Length <= Maximum_Length or else raise Constraint_Error,
        Post =>
           To_Vector'Result.Length = Length and then
           not Tampering_With_Elements_Prohibited (To_Vector'Result)
             and then
           not Tampering_With_Cursors_Prohibited (To_Vector'Result)
             and then
           To_Vector'Result.Capacity >= Length;
```

101/2 {*AI95-00302-03*} Returns a vector with a length of Length, filled with empty elements.

102/5
```
function To_Vector
  (New_Item : Element_Type;
   Length   : Count_Type) return Vector
   with Pre  => Length <= Maximum_Length or else raise Constraint_Error,
        Post =>
           To_Vector'Result.Length = Length and then
           not Tampering_With_Elements_Prohibited (To_Vector'Result)
             and then
           not Tampering_With_Cursors_Prohibited (To_Vector'Result)
             and then
        To_Vector'Result.Capacity >= Length;
```

103/2 {*AI95-00302-03*} Returns a vector with a length of Length, filled with elements initialized to the value New_Item.

104/5
```
function "&" (Left, Right : Vector) return Vector
   with Pre  => Length (Left) <= Maximum_Length - Length (Right)
                  or else raise Constraint_Error,
        Post => Length (Vectors."&"'Result) =
                   Length (Left) + Length (Right) and then
                not Tampering_With_Elements_Prohibited (Vectors."&"'Result)
                   and then
                not Tampering_With_Cursors_Prohibited (Vectors."&"'Result)
                   and then
                Vectors."&"'Result.Capacity >=
                   Length (Left) + Length (Right);
```

105/2 {*AI95-00302-03*} Returns a vector comprising the elements of Left followed by the elements of Right.

106/5
```
function "&" (Left  : Vector;
              Right : Element_Type) return Vector
   with Pre  => Length (Left) <= Maximum_Length - 1
                   or else raise Constraint_Error,
        Post => Vectors."&"'Result.Length = Length (Left) + 1 and then
                not Tampering_With_Elements_Prohibited (Vectors."&"'Result)
                   and then
                not Tampering_With_Cursors_Prohibited (Vectors."&"'Result)
                   and then
                Vectors."&"'Result.Capacity >= Length (Left) + 1;
```

107/2 {*AI95-00302-03*} Returns a vector comprising the elements of Left followed by the element Right.

```
function "&" (Left  : Element_Type;                                                    108/5
              Right : Vector) return Vector
   with Pre  => Length (Right) <= Maximum_Length - 1
                   or else raise Constraint_Error,
        Post => Length (Vectors."&"'Result) = Length (Right) + 1 and then
                not Tampering_With_Elements_Prohibited (Vectors."&"'Result)
                   and then
                not Tampering_With_Cursors_Prohibited (Vectors."&"'Result)
                   and then
                Vectors."&"'Result.Capacity >= Length (Right) + 1;
```

{*AI95-00302-03*} Returns a vector comprising the element Left followed by the elements of Right. 109/2

```
function "&" (Left, Right  : Element_Type) return Vector                               110/5
   with Pre  => Maximum_Length >= 2 or else raise Constraint_Error,
        Post => Length ("&"'Result) = 2 and then
                not Tampering_With_Elements_Prohibited (Vectors."&"'Result)
                   and then
                not Tampering_With_Cursors_Prohibited (Vectors."&"'Result)
                   and then
                Vectors."&"'Result.Capacity >= 2;
```

{*AI95-00302-03*} Returns a vector comprising the element Left followed by the element Right. 111/2

```
{AI12-0112-1} function Capacity (Container : Vector) return Count_Type                 112/5
   with Nonblocking, Global => null, Use_Formal => null;
```

{*AI95-00302-03*} Returns the capacity of Container. 113/2

```
{AI12-0112-1} procedure Reserve_Capacity (Container : in out Vector;                   114/5
                          Capacity  : in     Count_Type)
   with Pre  => not Tampering_With_Cursors_Prohibited (Container)
                   or else raise Program_Error,
        Post => Container.Capacity >= Capacity;
```

{*AI95-00302-03*} {*AI05-0001-1*} {*AI05-0264-1*} If the capacity of Container is already greater than or equal to Capacity, then Reserve_Capacity has no effect. Otherwise, Reserve_Capacity allocates additional storage as necessary to ensure that the length of the resulting vector can become at least the value Capacity without requiring an additional call to Reserve_Capacity, and is large enough to hold the current length of Container. Reserve_Capacity then, as necessary, moves elements into the new storage and deallocates any storage no longer needed. Any exception raised during allocation is propagated and Container is not modified. 115/3

Discussion: Expanding the internal array can be done by allocating a new, longer array, copying the elements, and deallocating the original array. This may raise Storage_Error, or cause an exception from a controlled subprogram. We require that a failed Reserve_Capacity does not lose any elements if an exception occurs, but we do not require a specific order of evaluations or copying. 115.a/2

This routine is used to preallocate the internal array to the specified capacity such that future Inserts do not require memory allocation overhead. Therefore, the implementation should allocate the needed memory to make that true at this point, even though the visible semantics could be preserved by waiting until the memory is needed. This doesn't apply to the indefinite element container, because elements will have to be allocated individually. 115.b/2

The implementation does not have to contract the internal array if the capacity is reduced, as any capacity greater than or equal to the specified capacity is allowed. 115.c/2

```
function Length (Container : Vector) return Count_Type                                 116/5
   with Nonblocking, Global => null, Use_Formal => null;
```

{*AI95-00302-03*} Returns the number of elements in Container. 117/2

118/5
```
procedure Set_Length (Container : in out Vector;
                      Length    : in     Count_Type)
   with Pre  => (not Tampering_With_Cursors_Prohibited (Container)
                    or else raise Program_Error) and then
                (Length <= Maximum_Length or else raise Constraint_Error),
        Post => Container.Length = Length and then
                Capacity (Container) >= Length;
```

119/3 {*AI95-00302-03*} {*AI05-0264-1*} If Length is larger than the capacity of Container, Set_Length calls Reserve_Capacity (Container, Length), then sets the length of the Container to Length. If Length is greater than the original length of Container, empty elements are added to Container; otherwise, elements are removed from Container.

119.a/2 **Ramification:** No elements are moved by this operation; any new empty elements are added at the end. This follows from the rules that a cursor continues to designate the same element unless the routine is defined to make the cursor ambiguous or invalid; this operation does not do that.

120/5
```
function Is_Empty (Container : Vector) return Boolean
   with Nonblocking, Global => null, Use_Formal => null,
        Post => Is_Empty'Result = (Length (Container) = 0);
```

121/5 {*AI95-00302-03*} {*AI12-0112-1*} Returns True if Container is empty.

122/5
```
procedure Clear (Container : in out Vector)
   with Pre  => not Tampering_With_Cursors_Prohibited (Container)
                    or else raise Program_Error,
        Post => Length (Container) = 0;
```

123/2 {*AI95-00302-03*} Removes all the elements from Container. The capacity of Container does not change.

124/5
```
function To_Cursor (Container : Vector;
                    Index     : Extended_Index) return Cursor
   with Post => (if Index in
                    First_Index (Container) .. Last_Index (Container)
                 then Has_Element (Container, To_Cursor'Result)
                 else To_Cursor'Result = No_Element),
        Nonblocking, Global => null, Use_Formal => null;
```

125/5 {*AI95-00302-03*} {*AI12-0112-1*} {*AI12-0196-1*} Returns a cursor designating the element at position Index in Container; returns No_Element if Index does not designate an element. For the purposes of determining whether the parameters overlap in a call to To_Cursor, the Container parameter is not considered to overlap with any object [(including itself)].

125.a/5 **Reason:** {*AI12-0196-1*} Without the preceding rule, concurrent calls to To_Cursor on the same container would interfere by the concurrent call rules in Annex A, since the container object of the concurrent calls would overlap with itself. We want these to not interfere, for example to allow the Vector elements to be split into separate “chunks” for parallel processing.

126/5
```
function To_Index (Position  : Cursor) return Extended_Index
   with Nonblocking, Global => in all, Use_Formal => null;
```

127/2 {*AI95-00302-03*} If Position is No_Element, No_Index is returned. Otherwise, the index (within its containing vector) of the element designated by Position is returned.

127.a/2 **Ramification:** This implies that the index is determinable from a bare cursor alone. The basic model is that a vector cursor is implemented as a record containing an access to the vector container and an index value. This does constrain implementations, but it also allows all of the cursor operations to be defined in terms of the corresponding index operation (which should be primary for a vector).

```
function To_Index (Container : Vector;                                          127.1/5
                   Position  : Cursor) return Extended_Index
   with Pre  => Position = No_Element or else
                Has_Element (Container, Position)  or else
                   raise Program_Error,
        Post => (if Position = No_Element then To_Index'Result = No_Index
                 else To_Index'Result in First_Index (Container) ..
                      Last_Index (Container)),
        Nonblocking, Global => null, Use_Formal => null;
```

{*AI12-0112-1*} Returns the index (within Container) of the element designated by Position; returns No_Index if Position does not designate an element. For the purposes of determining whether the parameters overlap in a call to To_Index, the Container parameter is not considered to overlap with any object [(including itself)]. 127.2/5

```
function Element (Container : Vector;                                           128/5
                  Index     : Index_Type)
   return Element_Type
   with Pre  => Index in First_Index (Container) .. Last_Index (Container)
                   or else raise Constraint_Error,
        Nonblocking, Global => null, Use_Formal => Element_Type;
```

{*AI95-00302-03*} {*AI12-0112-1*} Element returns the element at position Index. 129/5

```
function Element (Position  : Cursor) return Element_Type                       130/5
   with Pre  => Position /= No_Element or else raise Constraint_Error,
        Nonblocking, Global => in all, Use_Formal => Element_Type;
```

{*AI95-00302-03*} {*AI12-0112-1*} Element returns the element designated by Position. 131/5

```
function Element (Container : Vector;                                           131.1/5
                  Position  : Cursor) return Element_Type
   with Pre => (Position /= No_Element
                   or else raise Constraint_Error) and then
               (Has_Element (Container, Position)
                   or else raise Program_Error),
        Nonblocking, Global => null, Use_Formal => Element_Type;
```

{*AI12-0112-1*} Element returns the element designated by Position in Container. 131.2/5

```
procedure Replace_Element (Container : in out Vector;                           132/5
                           Index     : in     Index_Type;
                           New_Item  : in     Element_Type)
   with Pre => (not Tampering_With_Elements_Prohibited (Container)
                   or else raise Program_Error) and then
               (Index in First_Index (Container) .. Last_Index (Container)
                   or else raise Constraint_Error);
```

{*AI95-00302-03*} {*AI05-0264-1*} {*AI12-0112-1*} {*AI12-0196-1*} Replace_Element assigns the value New_Item to the element at position Index. Any exception raised during the assignment is propagated. The element at position Index is not an empty element after successful call to Replace_Element. For the purposes of determining whether the parameters overlap in a call to Replace_Element, the Container parameter is not considered to overlap with any object [(including itself)], and the Index parameter is considered to overlap with the element at position Index. 133/5

134/5
```
procedure Replace_Element (Container : in out Vector;
                           Position  : in     Cursor;
                           New_Item  : in     Element_Type)
   with Pre  => (not Tampering_With_Elements_Prohibited (Container)
                    or else raise Program_Error) and then
                 (Position /= No_Element
                    or else raise Constraint_Error) and then
                 (Has_Element (Container, Position)
                    or else raise Program_Error);
```

135/5 {*AI95-00302-03*} {*AI05-0264-1*} {*AI12-0112-1*} {*AI12-0196-1*} Replace_Element assigns New_Item to the element designated by Position. Any exception raised during the assignment is propagated. The element at Position is not an empty element after successful call to Replace_Element. For the purposes of determining whether the parameters overlap in a call to Replace_Element, the Container parameter is not considered to overlap with any object [(including itself)].

135.a/3 **Ramification:** {*AI05-0212-1*} Replace_Element, Update_Element, and Reference are the only ways that an element can change from empty to nonempty. Also see the note following Update_Element.

136/5
```
procedure Query_Element
  (Container : in Vector;
   Index     : in Index_Type;
   Process   : not null access procedure (Element : in Element_Type))
   with Pre  => Index in First_Index (Container) .. Last_Index (Container)
                   or else raise Constraint_Error;
```

137/5 {*AI95-00302-03*} {*AI05-0265-1*} {*AI12-0112-1*} Query_Element calls Process.**all** with the element at position Index as the argument. Tampering with the elements of Container is prohibited during the execution of the call on Process.**all**. Any exception raised by Process.**all** is propagated.

137.a/2 **Reason:** {*AI05-0005-1*} The "tamper with the elements" check is intended to prevent the Element parameter of Process from being replaced or deleted outside of Process. The check prevents data loss (if Element_Type is passed by copy) or erroneous execution (if Element_Type is an unconstrained type in an indefinite container).

138/5
```
procedure Query_Element
  (Position : in Cursor;
   Process  : not null access procedure (Element : in Element_Type))
   with Pre  => Position /= No_Element or else raise Constraint_Error
        Global => in all;
```

139/5 {*AI95-00302-03*} {*AI05-0021-1*} {*AI05-0265-1*} {*AI12-0112-1*} Query_Element calls Process.**all** with the element designated by Position as the argument. Tampering with the elements of the vector that contains the element designated by Position is prohibited during the execution of the call on Process.**all**. Any exception raised by Process.**all** is propagated.

139.1/5
```
procedure Query_Element
  (Container : in Vector;
   Position  : in Cursor;
   Process   : not null access procedure (Element : in Element_Type))
   with Pre  => (Position /= No_Element
                    or else raise Constraint_Error) and then
                (Has_Element (Container, Position)
                    or else raise Program_Error);
```

139.2/5 {*AI12-0112-1*} Query_Element calls Process.**all** with the element designated by Position as the argument. Tampering with the elements of Container is prohibited during the execution of the call on Process.**all**. Any exception raised by Process.**all** is propagated.

```
procedure Update_Element                                                    140/5
  (Container : in out Vector;
   Index     : in     Index_Type;
   Process   : not null access procedure
                     (Element : in out Element_Type))
   with Pre  => Index in First_Index (Container) .. Last_Index (Container)

        Default_Initial_Condition => (raise Program_Error);
```

{*AI05-0212-1*} The types Constant_Reference_Type and Reference_Type need finalization. 147.3/3

This paragraph was deleted.{*AI12-0112-1*} 147.4/5

Reason: It is expected that Reference_Type (and Constant_Reference_Type) will be a controlled type, for which finalization will have some action to terminate the tampering check for the associated container. If the object is created 147.a/3

by default, however, there is no associated container. Since this is useless, and supporting this case would take extra work, we define it to raise an exception.

147.5/5
```
{AI12-0112-1} function Constant_Reference (Container : aliased in Vector;
                                           Index     : in Index_Type)
   return Constant_Reference_Type
   with Pre    => Index in First_Index (Container) .. Last_Index (Container)
                     or else raise Constraint_Error,
        Post   => Tampering_With_Cursors_Prohibited (Container),
        Nonblocking, Global => null, Use_Formal => null;
```

147.6/3 {*AI05-0212-1*} {*AI05-0269-1*} This function (combined with the Constant_Indexing and Implicit_Dereference aspects) provides a convenient way to gain read access to an individual element of a vector given an index value.

147.7/5 {*AI05-0212-1*} {*AI05-0265-1*} {*AI12-0112-1*} Constant_Reference returns an object whose discriminant is an access value that designates the element at position Index. Tampering with the elements of Container is prohibited while the object returned by Constant_Reference exists and has not been finalized.

147.8/5
```
{AI12-0112-1} function Reference (Container : aliased in out Vector;

        Nonblocking, Global => null, Use_Formal => null;
```

{*AI05-0212-1*} {*AI05-0269-1*} This function (combined with the Variable_Indexing and Implicit_Dereference aspects) provides a convenient way to gain read and write access to an individual element of a vector given a cursor. 147.16/3

{*AI05-0212-1*} {*AI05-0265-1*} {*AI12-0112-1*} Reference returns an object whose discriminant is an access value that designates the element designated by Position. Tampering with the elements of Container is prohibited while the object returned by Reference exists and has not been finalized. 147.17/5

The element designated by Position is not an empty element after successful completion of this operation. 147.18/3

```
procedure Assign (Target : in out Vector; Source : in Vector)                           147.19/3
   with Pre  => not Tampering_With_Cursors_Prohibited (Target)
                    or else raise Program_Error,
        Post => Length (Source) = Length (Target) and then
                Capacity (Target) >= Length (Target);
```

{*AI05-0001-1*} {*AI05-0248-1*} {*AI05-0262-1*} If Target denotes the same object as Source, the operation has no effect. If the length of Source is greater than the capacity of Target, Reserve_Capacity (Target, Length (Source)) is called. The elements of Source are then copied to Target as for an assignment_statement assigning Source to Target (this includes setting the length of Target to be that of Source). 147.20/3

Discussion: {*AI05-0005-1*} This routine exists for compatibility with the bounded vector container. For an unbounded vector, `Assign(A, B)` and `A := B` behave identically. For a bounded vector, := will raise an exception if the container capacities are different, while Assign will not raise an exception if there is enough room in the target. 147.b/3

```
function Copy (Source : Vector; Capacity : Count_Type := 0)                             147.21/5
   return Vector
   with Pre => Capacity = 0 or else Capacity >= Length (Source)
                    or else raise Capacity_Error,
        Post => Length (Copy'Result) = Length (Source) and then
                not Tampering_With_Elements_Prohibited (Copy'Result)
                   and then
                not Tampering_With_Cursors_Prohibited (Copy'Result)
                   and then
                Copy'Result.Capacity >= (if Capacity = 0 then
                   Length (Source) else Capacity);
```

{*AI05-0001-1*} {*AI12-0112-1*} Returns a vector whose elements are initialized from the corresponding elements of Source. 147.22/5

148/5
```
procedure Move (Target : in out Vector;
                Source : in out Vector)
   with Pre  => (not Tampering_With_Cursors_Prohibited (Target)
                   or else raise Program_Error) and then
                (not Tampering_With_Cursors_Prohibited (Source)
                   or else raise Program_Error),
        Post => (if not Target'Has_Same_Storage (Source) then
                    Length (Target) = Length (Source)'Old and then
                    Length (Source) = 0 and then
                    Capacity (Target) >= Length (Source)'Old);
```

149/5 {*AI95-00302-03*} {*AI05-0001-1*} {*AI05-0248-1*} {*AI12-0112-1*} If Target denotes the same object as Source, then the operation has no effect. Otherwise, Move first calls Reserve_Capacity (Target, Length (Source)) and then Clear (Target); then, each element from Source is removed from Source and inserted into Target in the original order.

149.a/2 **Discussion:** The idea is that the internal array is removed from Source and moved to Target. (See the Implementation Advice for Move). If Capacity (Target) /= 0, the previous internal array may need to be deallocated. We don't mention this explicitly, because it is covered by the "no memory loss" Implementation Requirement.

150/5
```
procedure Insert_Vector (Container : in out Vector;
                         Before    : in     Extended_Index;
                         New_Item  : in     Vector)
   with Pre  => (not Tampering_With_Cursors_Prohibited (Container)
                   or else raise Program_Error) and then
                (Before in
                   First_Index (Container) .. Last_Index (Container) + 1
                   or else raise Constraint_Error) and then
                (Length (Container) <= Maximum_Length - Length (New_Item)
                   or else raise Constraint_Error),
        Post => Length (Container)'Old + Length (New_Item) =
                   Length (Container) and then
                Capacity (Container) >= Length (Container);
```

151/5 {*AI95-00302-03*} {*AI05-0264-1*} {*AI12-0112-1*} {*AI12-0400-1*} If Length(New_Item) is 0, then Insert_Vector does nothing. Otherwise, it computes the new length *NL* as the sum of the current length and Length (New_Item); if the value of Last appropriate for length *NL* would be greater than Index_Type'Last, then Constraint_Error is propagated.

152/5 {*AI12-0400-1*} If the current vector capacity is less than *NL*, Reserve_Capacity (Container, *NL*) is called to increase the vector capacity. Then Insert_Vector slides the elements in the range Before .. Last_Index (Container) up by Length(New_Item) positions, and then copies the elements of New_Item to the positions starting at Before. Any exception raised during the copying is propagated.

152.a/2 **Ramification:** Moving the elements does not necessarily involve copying. Similarly, since Reserve_Capacity does not require the copying of elements, it does not need to be explicitly called (the implementation can combine the operations if it wishes to).

153/5
```
procedure Insert_Vector (Container : in out Vector;
                         Before    : in     Cursor;
                         New_Item  : in     Vector)
   with Pre  => (not Tampering_With_Cursors_Prohibited (Container)
                   or else raise Program_Error) and then
                (Before = No_Element or else
                 Has_Element (Container, Before)
                   or else raise Program_Error) and then
                (Length (Container) <= Maximum_Length - Length (New_Item)
                   or else raise Constraint_Error),
        Post => Length (Container)'Old + Length (New_Item) =
                   Length (Container) and then
                Capacity (Container) >= Length (Container);
```

154/5 {*AI95-00302-03*} {*AI05-0264-1*} {*AI12-0112-1*} {*AI12-0400-1*} If Length(New_Item) is 0, then Insert_Vector does nothing. If Before is No_Element, then the call is equivalent to Insert_Vector

(Container, Last_Index (Container) + 1, New_Item); otherwise, the call is equivalent to Insert_Vector (Container, To_Index (Before), New_Item);

Ramification: The check on Before checks that the cursor does not belong to some other Container. This check implies that a reference to the container is included in the cursor value. This wording is not meant to require detection of dangling cursors; such cursors are defined to be invalid, which means that execution is erroneous, and any result is allowed (including not raising an exception). 154.a/2

```
procedure Insert_Vector (Container : in out Vector;                                    155/5
                         Before    : in     Cursor;
                         New_Item  : in     Vector;
                         Position  :    out Cursor)
   with Pre  => (not Tampering_With_Cursors_Prohibited (Container)
                    or else raise Program_Error) and then
                 (Before = No_Element or else
                  Has_Element (Container, Before)
                    or else raise Program_Error) and then
                 (Length (Container) <= Maximum_Length - Length (New_Item)
                    or else raise Constraint_Error),
        Post => Length (Container)'Old + Length (New_Item) =
                    Length (Container) and then
                 Has_Element (Container, Position) and then
                 Capacity (Container) >= Length (Container);
```

{*AI95-00302-03*} {*AI12-0112-1*} {*AI12-0400-1*} If Before equals No_Element, then let *T* be Last_Index (Container) + 1; otherwise, let *T* be To_Index (Before). Insert_Vector (Container, *T*, New_Item) is called, and then Position is set to To_Cursor (Container, *T*). 156/5

Discussion: {*AI12-0400-1*} The messy wording is needed because Before is invalidated by Insert_Vector, and we don't want Position to be invalid after this call. An implementation probably only needs to copy Before to Position. 156.a/5

```
{AI12-0112-1} procedure Insert (Container : in out Vector;                             157/5
                   Before    : in     Extended_Index;
                   New_Item  : in     Element_Type;
                   Count     : in     Count_Type := 1)
   with Pre  => (not Tampering_With_Cursors_Prohibited (Container)
                    or else raise Program_Error) and then

                Capacity (Container) >= Length (Container);
```

164/5 {*AI95-00302-03*} {*AI05-0264-1*} {*AI12-0112-1*} If Count is 0, then Insert does nothing. Otherwise, it computes the new length *NL* as the sum of the current length and Count; if the value of Last appropriate for length *NL* would be greater than Index_Type'Last, then Constraint_Error is propagated.

165/2 If the current vector capacity is less than *NL*, Reserve_Capacity (Container, *NL*) is called to increase the vector capacity. Then Insert slides the elements in the range Before .. Last_Index (Container) up by Count positions, and then inserts elements that are initialized by default (see 3.3.1) in the positions starting at Before.

166/5
```
procedure Insert (Container : in out Vector;
                  Before    : in     Cursor;
                  Position  :    out Cursor;
                  Count     : in     Count_Type := 1)
   with Pre  => (not Tampering_With_Cursors_Prohibited (Container)
                   or else raise Program_Error) and then
                (Before = No_Element or else
                 Has_Element (Container, Before)
                   or else raise Program_Error) and then
                (Length (Container) <= Maximum_Length - Count
                   or else raise Constraint_Error),
        Post => Length (Container)'Old + Count = Length (Container) and then
                Has_Element (Container, Position) and then
                Capacity (Container) >= Length (Container);
```

167/5 {*AI95-00302-03*} {*AI12-0112-1*} If Before equals No_Element, then let *T* be Last_Index (Container) + 1; otherwise, let *T* be To_Index (Before). Insert (Container, *T*, Count) is called, and then Position is set to To_Cursor (Container, *T*).

Reason: This routine exists mainly to ease conversion between Vector and List containers. Unlike Insert_Space, this routine default initializes the elements it inserts, which can be more expensive for some element types. 167.a/2

```

```
{AI05-0092-1} {AI12-0112-1} procedure Reverse_Elements (Container : in out Vector)  189/5
   with Pre  => not Tampering_With_Cursors_Prohibited (Container)
                    or else raise Program_Error;
```

{*AI95-00302-03*} Reorders the elements of Container in reverse order. 190/2

Discussion: This can copy the elements of the vector — all cursors referencing the vector are ambiguous afterwards and may designate different elements afterwards. 190.a/2

```
procedure Swap (Container : in out Vector;                                      191/5
                I, J      : in     Index_Type)
   with Pre => (not Tampering_With_Elements_Prohibited (Container)
                   or else raise Program_Error) and then
               (I in First_Index (Container) .. Last_Index (Container)
                   or else raise Constraint_Error) and then
               (J in First_Index (Container) .. Last_Index (Container)
                   or else raise Constraint_Error);
```

{*AI95-00302-03*} {*AI12-0112-1*} Swap exchanges the values of the elements at positions I and J. 192/5

To be honest: The implementation is not required to actually copy the elements if it can do the swap some other way. But it is allowed to copy the elements if needed. 192.a/2

193/5
```
procedure Swap (Container : in out Vector;
                I, J      : in     Cursor)
   with Pre  => (not Tampering_With_Elements_Prohibited (Container)
                   or else raise Program_Error) and then
                (I /= No_Element or else Constraint_Error) and then
                (J /= No_Element or else Constraint_Error) and then
                (Has_Element (Container, I)
                   or else raise Program_Error) and then
                (Has_Element (Container, J)
                   or else raise Program_Error);
```

194/5 {*AI95-00302-03*} {*AI12-0112-1*} Swap exchanges the values of the elements designated by I and J.

194.a/2 **Ramification:** After a call to Swap, I designates the element value previously designated by J, and J designates the element value previously designated by I. The cursors do not become ambiguous from this operation.

194.b/2 **To be honest:** The implementation is not required to actually copy the elements if it can do the swap some other way. But it is allowed to copy the elements if needed.

195/5
```
{AI12-0112-1} function First_Index (Container : Vector) return Index_Type
   with Nonblocking, Global => null, Use_Formal => null,
        Post => First_Index'Result = Index_Type'First;
```

196/2 {*AI95-00302-03*} Returns the value Index_Type'First.

196.a/2 **Discussion:** We'd rather call this “First”, but then calling most routines in here with First (Some_Vect) would be ambiguous.

197/5
```
{AI12-0112-1} function First (Container : Vector) return Cursor
   with Nonblocking, Global => null, Use_Formal => null,
        Post => (if not Is_Empty (Container)
                 then Has_Element (Container, First'Result)
                 else First'Result = No_Element);
```

198/2 {*AI95-00302-03*} If Container is empty, First returns No_Element. Otherwise, it returns a cursor that designates the first element in Container.

199/5
```
{AI12-0112-1} function First_Element (Container : Vector)
   return Element_Type
   with Pre => (not Is_Empty (Container)

   with Nonblocking, Global => in all, Use_Formal => null;
```

214/2 {*AI95-00302-03*} Equivalent to Position := Previous (Position).

214.1/5
```
procedure Previous (Container : in     Vector;
                    Position  : in out Cursor)
   with Nonblocking, Global => null, Use_Formal => null,
        Pre  => Position = No_Element or else
                Has_Element (Container, Position)
                   or else raise Program_Error,
        Post => (if Position /= No_Element
                 then Has_Element (Container, Position));
```

214.2/5 {*AI12-0112-1*} Equivalent to Position := Previous (Container, Position).

215/2
```
function Find_Index (Container : Vector;
                     Item      : Element_Type;
                     Index     : Index_Type := Index_Type'First)
   return Extended_Index;
```

216/2 {*AI95-00302-03*} Searches the elements of Container for an element equal to Item (using the generic formal equality operator). The search starts at position Index and proceeds towards Last_Index (Container). If no equal element is found, then Find_Index returns No_Index. Otherwise, it returns the index of the first equal element encountered.

217/5
```
function Find (Container : Vector;
               Item      : Element_Type;
               Position  : Cursor := No_Element)
   return Cursor
   with Pre  => Position = No_Element or else
                Has_Element (Container, Position)
                   or else raise Program_Error,
        Post => (if Find'Result /= No_Element
                 then Has_Element (Container, Find'Result));
```

218/5 {*AI95-00302-03*} {*AI05-0264-1*} {*AI12-0112-1*} Find searches the elements of Container for an element equal to Item (using the generic formal equality operator). The search starts at the first element if Position equals No_Element, and at the element designated by Position otherwise. It proceeds towards the last element of Container. If no equal element is found, then Find returns No_Element. Otherwise, it returns a cursor designating the first equal element encountered.

219/2
```
function Reverse_Find_Index (Container : Vector;
                             Item      : Element_Type;
                             Index     : Index_Type := Index_Type'Last)
   return Extended_Index;
```

220/2 {*AI95-00302-03*} Searches the elements of Container for an element equal to Item (using the generic formal equality operator). The search starts at position Index or, if Index is greater than Last_Index (Container), at position Last_Index (Container). It proceeds towards First_Index (Container). If no equal element is found, then Reverse_Find_Index returns No_Index. Otherwise, it returns the index of the first equal element encountered.

```
function Reverse_Find (Container : Vector;                                    221/5
                       Item      : Element_Type;
                       Position  : Cursor := No_Element)
   return Cursor
   with Pre  => Position = No_Element or else
                Has_Element (Container, Position)
                   or else raise Program_Error,
        Post => (if Reverse_Find'Result /= No_Element
                 then Has_Element (Container, Reverse_Find'Result));
```

{*AI95-00302-03*} {*AI05-0264-1*} {*AI12-0112-1*} Reverse_Find searches the elements of Container for an element equal to Item (using the generic formal equality operator). The search starts at the last element if Position equals No_Element, and at the element designated by Position otherwise. It proceeds towards the first element of Container. If no equal element is found, then Reverse_Find returns No_Element. Otherwise, it returns a cursor designating the first equal element encountered. 222/5

```
function Contains (Container : Vector;                                        223/2
                   Item      : Element_Type) return Boolean;
```

{*AI95-00302-03*} Equivalent to Has_Element (Find (Container, Item)). 224/2

Paragraphs 225 and 226 were moved above.

```
{AI12-0112-1} procedure Iterate                                               227/5
  (Container : in Vector;
   Process   : not null access procedure (Position : in Cursor))
   with Allows_Exit;
```

{*AI95-00302-03*} {*AI05-0265-1*} Invokes Process.**all** with a cursor that designates each element in Container, in index order. Tampering with the cursors of Container is prohibited during the execution of a call on Process.**all**. Any exception raised by Process.**all** is propagated. 228/3

Discussion: The purpose of the "tamper with the cursors" check is to prevent erroneous execution from the Position parameter of Process.**all** becoming invalid. This check takes place when the operations that tamper with the cursors of the container are called. The check cannot be made later (say in the body of Iterate), because that could cause the Position cursor to be invalid and potentially cause execution to become erroneous -- defeating the purpose of the check. 228.a/2

There is no check needed if an attempt is made to insert or delete nothing (that is, Count = 0 or Length(Item) = 0). 228.b/2

The check is easy to implement: each container needs a counter. The counter is incremented when Iterate is called, and decremented when Iterate completes. If the counter is nonzero when an operation that inserts or deletes is called, Finalize is called, or one of the other operations in the list occurs, Program_Error is raised. 228.c/2

```
{AI12-0112-1} procedure Reverse_Iterate                                       229/5
  (Container : in Vector;
   Process   : not null access procedure (Position : in Cursor))
   with Allows_Exit;
```

{*AI95-00302-03*} {*AI05-0212-1*} Iterates over the elements in Container as per procedure Iterate, except that elements are traversed in reverse index order. 230/3

```
{AI12-0212-1} {AI12-0266-1} function Iterate (Container : in Vector)          230.1/5
   return Vector_Iterator_Interfaces.Parallel_Reversible_Iterator'Class
   with Post   => Tampering_With_Cursors_Prohibited (Container);
```

{*AI05-0212-1*} {*AI05-0265-1*} {*AI05-0269-1*} {*AI12-0266-1*} Iterate returns an iterator object (see 5.5.1) that will generate a value for a loop parameter (see 5.5.2) designating each node in Container, starting with the first node and moving the cursor as per the Next function when used as a forward iterator, and starting with the last node and moving the cursor as per the Previous function when used as a reverse iterator, and processing all nodes concurrently when used as a parallel iterator. Tampering with the cursors of Container is prohibited while the iterator object 230.2/5

exists (in particular, in the sequence_of_statements of the loop_statement whose iterator_specification denotes this object). The iterator object needs finalization.

230.3/5
```
function Iterate (Container : in Vector; Start : in Cursor)
   return Vector_Iterator_Interfaces.Reversible_Iterator'Class
   with Pre    => (Start /= No_Element
                      or else raise Constraint_Error) and then
                  (Has_Element (Container, Start)
                      or else raise Program_Error),
        Post   => Tampering_With_Cursors_Prohibited (Container);
```

230.4/5 {*AI05-0212-1*} {*AI05-0262-1*} {*AI05-0265-1*} {*AI05-0269-1*} {*AI12-0212-1*} Iterate returns a reversible iterator object (see 5.5.1) that will generate a value for a loop parameter (see 5.5.2) designating each node in Container, starting with the node designated by Start and moving the cursor as per the Next function when used as a forward iterator, or moving the cursor as per the Previous function when used as a reverse iterator. Tampering with the cursors of Container is prohibited while the iterator object exists (in particular, in the sequence_of_statements of the loop_statement whose iterator_specification denotes this object). The iterator object needs finalization.

230.a/3 **Discussion:** Exits are allowed from the loops created using the iterator objects. In particular, to stop the iteration at a particular cursor, just add

230.b/3
```
exit when Cur = Stop;
```

230.c/3 in the body of the loop (assuming that `Cur` is the loop parameter and `Stop` is the cursor that you want to stop at).

231/3 {*AI05-0044-1*} {*AI05-0262-1*} The actual function for the generic formal function "<" of Generic_Sorting is expected to return the same value each time it is called with a particular pair of element values. It should define a strict weak ordering relationship (see A.18); it should not modify Container. If the actual for "<" behaves in some other manner, the behavior of the subprograms of Generic_Sorting are unspecified. The number of times the subprograms of Generic_Sorting call "<" is unspecified.

232/2
```
function Is_Sorted (Container : Vector) return Boolean;
```

233/2 {*AI95-00302-03*} Returns True if the elements are sorted smallest first as determined by the generic formal "<" operator; otherwise, Is_Sorted returns False. Any exception raised during evaluation of "<" is propagated.

234/5
```
{AI12-0112-1} procedure Sort (Container : in out Vector)
   with Pre  => not Tampering_With_Cursors_Prohibited (Container)
                    or else raise Program_Error;
```

235/2 {*AI95-00302-03*} Reorders the elements of Container such that the elements are sorted smallest first as determined by the generic formal "<" operator provided. Any exception raised during evaluation of "<" is propagated.

235.a/2 **Ramification:** This implies swapping the elements, usually including an intermediate copy. This means that the elements will usually be copied. (As with Swap, if the implementation can do this some other way, it is allowed to.) Since the elements are nonlimited, this usually will not be a problem. Note that there is Implementation Advice below that the implementation should use a sort that minimizes copying of elements.

235.b/2 The sort is not required to be stable (and the fast algorithm required will not be stable). If a stable sort is needed, the user can include the original location of the element as an extra "sort key". We considered requiring the implementation to do that, but it is mostly extra overhead -- usually there is something already in the element that provides the needed stability.

```
procedure Merge (Target  : in out Vector;                                    236/5
                 Source  : in out Vector)
   with Pre  => (not Tampering_With_Cursors_Prohibited (Target)
                    or else raise Program_Error) and then
                 (not Tampering_With_Cursors_Prohibited (Source)
                    or else raise Program_Error) and then
                 (Length (Target) <= Maximum_Length - Length (Source)
                    or else raise Constraint_Error) and then
                 ((Length (Source) = 0 or else
                    not Target'Has_Same_Storage (Source))
                    or else raise Program_Error),
        Post => (declare
                     Result_Length : constant Count_Type :=
                        Length (Source)'Old + Length (Target)'Old;
                  begin
                     (Length (Source) = 0 and then
                      Length (Target) = Result_Length and then
                      Capacity (Target) >= Result_Length));
```

{*AI95-00302-03*} {*AI05-0021-1*} {*AI12-0112-1*} Merge removes elements from Source and inserts them into Target; afterwards, Target contains the union of the elements that were initially in Source and Target; Source is left empty. If Target and Source are initially sorted smallest first, then Target is ordered smallest first as determined by the generic formal "<" operator; otherwise, the order of elements in Target is unspecified. Any exception raised during evaluation of "<" is propagated. 237/5

Discussion: It is a bounded error if either of the vectors is unsorted, see below. The bounded error can be recovered by sorting Target after the merge call, or the vectors can be pretested with Is_Sorted. 237.a/2

Implementation Note: The Merge operation will usually require copying almost all of the elements. One implementation strategy would be to extend Target to the appropriate length, then copying elements from the back of the vectors working towards the front. An alternative approach would be to allocate a new internal data array of the appropriate length, copy the elements into it in an appropriate order, and then replacing the data array in Target with the temporary. 237.b/2

{*AI12-0111-1*} The nested package Vectors.Stable provides a type Stable.Vector that represents a *stable* vector, which is one that cannot grow and shrink. Such a vector can be created by calling the To_Vector or Copy functions, or by establishing a *stabilized view* of an ordinary vector. 237.1/5

{*AI12-0111-1*} The subprograms of package Containers.Vectors that have a parameter or result of type Vector are included in the nested package Stable with the same specification, except that the following are omitted: 237.2/5

{*AI12-0111-1*} {*AI12-0400-1*} Tampering_With_Cursors_Prohibited, Tampering_With_Elements_Prohibited, Reserve_Capacity, Assign, Move, Insert, Insert_Space, Insert_Vector, Append, Append_Vector, Prepend, Prepend_Vector, Clear, Delete, Delete_First, Delete_Last, and Set_Length 237.3/5

The generic package Generic_Sorting is also included with the same specification, except that Merge is omitted. 237.4/5

Ramification: The names Vector and Cursor mean the types declared in the nested package in these subprogram specifications. 237.b.1/5

Reason: The omitted routines are those that tamper with cursors or elements (or test that state). The model is that it is impossible to tamper with cursors or elements of a stable view since no such operations are included. Thus tampering checks are not needed for a stable view, and we omit the operations associated with those checks. 237.b.2/5

{*AI12-0111-1*} The operations of this package are equivalent to those for ordinary vectors, except that the calls to Tampering_With_Cursors_Prohibited and Tampering_With_Elements_Prohibited that occur in preconditions are replaced by False, and any that occur in postconditions are replaced by True. 237.5/5

237.6/5 {*AI12-0111-1*} {*AI12-0439-1*} If a stable vector is declared with the Base discriminant designating a pre-existing ordinary vector, the stable vector represents a stabilized view of the underlying ordinary vector, and any operation on the stable vector is reflected on the underlying ordinary vector. While a stabilized view exists, any operation that tampers with elements performed on the underlying vector is prohibited. The finalization of a stable vector that provides such a view removes this restriction on the underlying ordinary vector [(though some other restriction can exist due to other concurrent iterations or stabilized views)].

237.7/5 {*AI12-0111-1*} {*AI12-0438-1*} If a stable vector is declared without specifying Base, the object is necessarily initialized. The initializing expression of the stable vector, [typically a call on To_Vector or Copy], determines the Length of the vector. The Length of a stable vector never changes after initialization.

237.c/5 **Proof:** {*AI12-0438-1*} Initialization is required as the type is indefinite, see 3.3.1.

Bounded (Run-Time) Errors

238/3 {*AI95-00302-03*} {*AI05-0212-1*} Reading the value of an empty element by calling Element, Query_Element, Update_Element, Constant_Reference, Reference, Swap, Is_Sorted, Sort, Merge, "=", Find, or Reverse_Find is a bounded error. The implementation may treat the element as having any normal value (see 13.9.1) of the element type, or raise Constraint_Error or Program_Error before modifying the vector.

238.a/2 **Ramification:** For instance, a default initialized element could be returned. Or some previous value of an element. But returning random junk is not allowed if the type has default initial value(s).

238.b/2 Assignment and streaming of empty elements are **not** bounded errors. This is consistent with regular composite types, for which assignment and streaming of uninitialized components do not cause a bounded error, but reading the uninitialized component does cause a bounded error.

238.c/2 There are other operations which are defined in terms of the operations listed above.

239/2 {*AI95-00302-03*} Calling Merge in an instance of Generic_Sorting with either Source or Target not ordered smallest first using the provided generic formal "<" operator is a bounded error. Either Program_Error is raised after Target is updated as described for Merge, or the operation works as defined.

239.1/3 {*AI05-0022-1*} {*AI05-0248-1*} It is a bounded error for the actual function associated with a generic formal subprogram, when called as part of an operation of this package, to tamper with elements of any Vector parameter of the operation. Either Program_Error is raised, or the operation works as defined on the value of the Vector either prior to, or subsequent to, some or all of the modifications to the Vector.

239.2/3 {*AI05-0027-1*} It is a bounded error to call any subprogram declared in the visible part of Containers.Vectors when the associated container has been finalized. If the operation takes Container as an **in out** parameter, then it raises Constraint_Error or Program_Error. Otherwise, the operation either proceeds as it would for an empty container, or it raises Constraint_Error or Program_Error.

240/2 {*AI95-00302-03*} A Cursor value is *ambiguous* if any of the following have occurred since it was created:

241/5 - {*AI12-0400-1*} Insert, Insert_Space, Insert_Vector, or Delete has been called on the vector that contains the element the cursor designates with an index value (or a cursor designating an element at such an index value) less than or equal to the index value of the element designated by the cursor; or

242/2 - The vector that contains the element it designates has been passed to the Sort or Merge procedures of an instance of Generic_Sorting, or to the Reverse_Elements procedure.

243/2 {*AI95-00302-03*} It is a bounded error to call any subprogram other than "=" or Has_Element declared in Containers.Vectors with an ambiguous (but not invalid, see below) cursor parameter. Possible results are:

244/2 - The cursor may be treated as if it were No_Element;

- The cursor may designate some element in the vector (but not necessarily the element that it originally designated); 245/2
- Constraint_Error may be raised; or 246/2
- Program_Error may be raised. 247/2

Reason: Cursors are made ambiguous if an Insert or Delete occurs that moves the elements in the internal array including the designated ones. After such an operation, the cursor probably still designates an element (although it might not after a deletion), but it is a *different* element. That violates the definition of cursor — it designates a particular element. 247.a/2

For "=" or Has_Element, the cursor works normally (it would not be No_Element). We don't want to trigger an exception simply for comparing a bad cursor. 247.b/2

While it is possible to check for these cases or ensure that cursors survive such operations, in many cases the overhead necessary to make the check (or ensure cursors continue to designate the same element) is substantial in time or space. 247.c/2

Erroneous Execution

{*AI95-00302-03*} A Cursor value is *invalid* if any of the following have occurred since it was created: 248/2

- The vector that contains the element it designates has been finalized; 249/2
- {*AI05-0160-1*} The vector that contains the element it designates has been used as the Target of a call to Assign, or as the target of an assignment_statement; 249.1/3
- [The vector that contains the element it designates has been used as the Source or Target of a call to Move;] or 250/2

Proof: {*AI05-0001-1*} Move has been reworded in terms of Assign and Clear, which are covered by other bullets, so this text is redundant. 250.a/3

- {*AI05-0160-1*} {*AI05-0262-1*} The element it designates has been deleted or removed from the vector that previously contained the element. 251/3

Ramification: {*AI05-0160-1*} An element can be removed via calls to Set_Length, Clear, and Merge; and indirectly via calls to Assign and Move. 251.a/3

{*AI95-00302-03*} The result of "=" or Has_Element is unspecified if it is called with an invalid cursor parameter. Execution is erroneous if any other subprogram declared in Containers.Vectors is called with an invalid cursor parameter. 252/2

Discussion: The list above (combined with the bounded error cases) is intended to be exhaustive. In other cases, a cursor value continues to designate its original element. For instance, cursor values survive the appending of new elements. 252.a/2

{*AI05-0212-1*} Execution is erroneous if the vector associated with the result of a call to Reference or Constant_Reference is finalized before the result object returned by the call to Reference or Constant_Reference is finalized. 252.1/3

Reason: Each object of Reference_Type and Constant_Reference_Type probably contains some reference to the originating container. If that container is prematurely finalized (which is only possible via Unchecked_Deallocation, as accessibility checks prevent passing a container to Reference that will not live as long as the result), the finalization of the object of Reference_Type will try to access a nonexistent object. This is a normal case of a dangling pointer created by Unchecked_Deallocation; we have to explicitly mention it here as the pointer in question is not visible in the specification of the type. (This is the same reason we have to say this for invalid cursors.) 252.b/3

Implementation Requirements

{*AI95-00302-03*} No storage associated with a vector object shall be lost upon assignment or scope exit. 253/2

{*AI95-00302-03*} {*AI05-0262-1*} The execution of an assignment_statement for a vector shall have the effect of copying the elements from the source vector object to the target vector object and changing the length of the target object to that of the source object. 254/3

Implementation Note: {*AI05-0298-1*} {*AI12-0005-1*} An assignment of a Vector is a “deep” copy; that is the elements are copied as well as the data structures. We say “effect of” in order to allow the implementation to avoid 254.a/5

copying elements immediately if it wishes. For instance, an implementation that avoided copying until one of the containers is modified would be allowed. (Note that such an implementation would require care, as Query_Element and Constant_Reference both could be used to access an element which later needs to be reallocated while the parameter or reference still exists, potentially leaving the parameter or reference pointing at the wrong element.)

Implementation Advice

255/2 {*AI95-00302-03*} Containers.Vectors should be implemented similarly to an array. In particular, if the length of a vector is *N*, then

256/2 • the worst-case time complexity of Element should be *O*(log *N*);

256.a/2 **Implementation Advice:** The worst-case time complexity of Element for Containers.Vector should be *O*(log *N*).

257/2 • the worst-case time complexity of Append with Count=1 when *N* is less than the capacity of the vector should be *O*(log *N*); and

257.a/2 **Implementation Advice:** The worst-case time complexity of Append with Count = 1 when *N* is less than the capacity for Containers.Vector should be *O*(log *N*).

258/2 • the worst-case time complexity of Prepend with Count=1 and Delete_First with Count=1 should be *O*(*N* log *N*).

258.a/2 **Implementation Advice:** The worst-case time complexity of Prepend with Count = 1 and Delete_First with Count=1 for Containers.Vectors should be *O*(*N* log *N*).

258.b/2 **Reason:** We do not mean to overly constrain implementation strategies here. However, it is important for portability that the performance of large containers has roughly the same factors on different implementations. If a program is moved to an implementation that takes *O*(*N*) time to access elements, that program could be unusable when the vectors are large. We allow *O*(log *N*) access because the proportionality constant and caching effects are likely to be larger than the log factor, and we don't want to discourage innovative implementations.

259/2 {*AI95-00302-03*} The worst-case time complexity of a call on procedure Sort of an instance of Containers.Vectors.Generic_Sorting should be *O*(*N***2), and the average time complexity should be better than *O*(*N***2).

259.a/2 **Implementation Advice:** The worst-case time complexity of a call on procedure Sort of an instance of Containers.Vectors.Generic_Sorting should be *O*(*N***2), and the average time complexity should be better than *O*(*N***2).

259.b/2 **Ramification:** In other words, we're requiring the use of a better than *O*(*N***2) sorting algorithm, such as Quicksort. No bubble sorts allowed!

260/2 {*AI95-00302-03*} Containers.Vectors.Generic_Sorting.Sort and Containers.Vectors.Generic_Sorting.Merge should minimize copying of elements.

260.a/2 **Implementation Advice:** Containers.Vectors.Generic_Sorting.Sort and Containers.Vectors.Generic_Sorting.Merge should minimize copying of elements.

260.b/2 **To be honest:** We do not mean “absolutely minimize” here; we're not intending to require a single copy for each element. Rather, we want to suggest that the sorting algorithm chosen is one that does not copy items unnecessarily. Bubble sort would not meet this advice, for instance.

261/2 {*AI95-00302-03*} Move should not copy elements, and should minimize copying of internal data structures.

261.a/2 **Implementation Advice:** Containers.Vectors.Move should not copy elements, and should minimize copying of internal data structures.

261.b/2 **Implementation Note:** Usually that can be accomplished simply by moving the pointer(s) to the internal data structures from the Source vector to the Target vector.

262/2 {*AI95-00302-03*} If an exception is propagated from a vector operation, no storage should be lost, nor any elements removed from a vector unless specified by the operation.

262.a/2 **Implementation Advice:** If an exception is propagated from a vector operation, no storage should be lost, nor any elements removed from a vector unless specified by the operation.

262.b/2 **Reason:** This is important so that programs can recover from errors. But we don't want to require heroic efforts, so we just require documentation of cases where this can't be accomplished.

NOTE 1 {*AI12-0440-1*} All elements of a vector occupy locations in the internal array. If a sparse container is required, a Hashed_Map can be used rather than a vector. 263/5

NOTE 2 If Index_Type'Base'First = Index_Type'First an instance of Ada.Containers.Vectors will raise Constraint_Error. A value below Index_Type'First is required so that an empty vector has a meaningful value of Last_Index. 264/2

Discussion: This property is the main reason why only integer types (as opposed to any discrete type) are allowed as the index type of a vector. An enumeration or modular type would require a subtype in order to meet this requirement. 264.a/2

Extensions to Ada 95

{*AI95-00302-03*} The package Containers.Vectors is new. 264.b/2

Incompatibilities With Ada 2005

{*AI05-0001-1*} Subprograms Assign and Copy are added to Containers.Vectors. If an instance of Containers.Vectors is referenced in a use_clause, and an entity *E* with the same defining_identifier as a new entity in Containers.Vectors is defined in a package that is also referenced in a use_clause, the entity *E* may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur. 264.c/3

Extensions to Ada 2005

{*AI05-0212-1*} Added iterator, reference, and indexing support to make vector containers more convenient to use. 264.d/3

Wording Changes from Ada 2005

{*AI05-0001-1*} Generalized the definition of Reserve_Capacity and Move. Specified which elements are read/written by stream attributes. 264.e/3

{*AI05-0022-1*} **Correction:** Added a Bounded (Run-Time) Error to cover tampering by generic actual subprograms. 264.f/3

{*AI05-0027-1*} **Correction:** Added a Bounded (Run-Time) Error to cover access to finalized vector containers. 264.g/3

{*AI05-0044-1*} **Correction:** Redefined "<" actuals to require a strict weak ordering; the old definition allowed indeterminant comparisons that would not have worked in a container. 264.h/3

{*AI05-0084-1*} **Correction:** Added a pragma Remote_Types so that containers can be used in distributed programs. 264.i/3

{*AI05-0160-1*} **Correction:** Revised the definition of invalid cursors to cover missing (and new) cases. 264.j/3

{*AI05-0265-1*} **Correction:** Defined when a container prohibits tampering in order to more clearly define where the check is made and the exception raised. 264.k/3

Inconsistencies With Ada 2012

{*AI12-0111-1*} Tampering with elements is now defined to be equivalent to tampering with cursors for ordinary containers. If a program requires tampering detection to work, it might fail in Ada 2022. Specifically, if a program requires Program_Error to be raised by a routine that (only) tampers with elements in Ada 2012 (such as Replace_Element) when called in a context that does not allow tampering with elements (such as Update_Element), the routine will work as defined instead of raising Program_Error in Ada 2022. Needless to say, this shouldn't happen outside of test programs. Note that such contexts still prohibit tampering with cursors, so routines like Insert and Delete will still raise Program_Error in this case. 264.l/5

{*AI12-0112-1*} Trying to insert or concatenate more than Count_Type'Last elements will now raise Constraint_Error rather than Capacity_Error. This is extremely unlikely to happen, as Count_Type'Last is typically at least 2**31-1, so most such vectors will exceed memory before reaching this error. 264.m/5

Incompatibilities With Ada 2012

{*AI12-0111-1*} {*AI12-0112-1*} {*AI12-0339-1*} A number of new subprograms, types, and even a nested package were added to Containers.Vectors to better support contracts and stable views. Therefore, a use clause conflict is possible; see the introduction of Annex A for more on this topic. 264.n/5

{*AI12-0005-1*} {*AI12-0212-1*} {*AI12-0400-1*} Vector objects now support aggregates. This introduces a potential incompatibility for overloaded routines, including the "&" operations defined in this package. If the Element_Type of the vector is a type that allows aggregates (such as a record type), then calls to the "&" operations with an aggregate element will become ambiguous in Ada 2022, while they would have been legal in Ada 2012. This can be fixed by qualifying the aggregate with the element type. 264.o/5

{*AI12-0400-1*} **Correction:** The Insert, Append, and Prepend operations that operate on two vectors have been renamed Insert_Vector, Append_Vector, and Prepend_Vector, respectively. This was done in order to eliminate the aggregate ambiguity for the commonly used single element Append and Insert routines. The renamed routines are rarely used in Ada 2012 code, so the impact should be minimal. 264.p/5

Extensions to Ada 2012

264.q/5 {*AI12-0196-1*} **Correction:** To_Cursor and Replace_Element are now defined such that they can be used concurrently so long as they operate on different elements. This allows some container operations to be used in parallel without separate synchronization.

264.r/5 {*AI12-0212-1*} Vectors now support indexed container aggregates, so aggregate syntax can be used to create Vectors.

264.s/5 {*AI12-0266-1*} The iterator for the entire container now can return a parallel iterator which can be used to process the container in parallel.

Wording Changes from Ada 2012

264.t/4 {*AI12-0110-1*} **Corrigendum:** Clarified that tampering checks precede all other checks made by a subprogram (but come after those associated with the call).

264.u/5 {*AI12-0112-1*} Added contracts to this container. This includes describing some of the semantics with pre- and postconditions, rather than English text. Note that the preconditions can be Suppressed (see 11.5).

264.v/5 {*AI12-0400-1*} **Correction:** Split the Append routine into two routines rather than having a single routine with a default parameter, in order that a routine with the appropriate profile for the Aggregate aspect exists. This change should not change the behavior of any existing code.

A.18.3 The Generic Package Containers.Doubly_Linked_Lists

1/2 {*AI95-00302-03*} The language-defined generic package Containers.Doubly_Linked_Lists provides private types List and Cursor, and a set of operations for each type. A list container is optimized for insertion and deletion at any position.

2/2 {*AI95-00302-03*} A doubly-linked list container object manages a linked list of internal *nodes*, each of which contains an element and pointers to the next (successor) and previous (predecessor) internal nodes. A cursor designates a particular node within a list (and by extension the element contained in that node). A cursor keeps designating the same node (and element) as long as the node is part of the container, even if the node is moved in the container.

3/2 {*AI95-00302-03*} The *length* of a list is the number of elements it contains.

Static Semantics

4/2 {*AI95-00302-03*} The generic library package Containers.Doubly_Linked_Lists has the following declaration:

5/5
```
{AI05-0084-1} {AI05-0212-1} {AI12-0112-1} with Ada.Iterator_Interfaces;
generic
   type Element_Type is private;
   with function "=" (Left, Right : Element_Type)
      return Boolean is <>;
package Ada.Containers.Doubly_Linked_Lists
   with Preelaborate, Remote_Types,
        Nonblocking, Global => in out synchronized is
```

5.a/5 **Discussion:** {*AI12-0112-1*} For discussion on the reasons and meaning of the specifications of the Global and Nonblocking aspects in this generic package, see the notes on the equivalent operations in the specification of the Containers.Vectors package (see A.18.2).

{*AI95-00302-03*} The actual function for the generic formal function "=" on Element_Type values is expected to define a reflexive and symmetric relationship and return the same result value each time it is called with a particular pair of values. If it behaves in some other manner, the functions Find, Reverse_Find, and "=" on list values return an unspecified value. The exact arguments and number of calls of this generic formal function by the functions Find, Reverse_Find, and "=" on list values are unspecified. 55/2

Ramification: If the actual function for "=" is not symmetric and consistent, the result returned by the listed functions cannot be predicted. The implementation is not required to protect against "=" raising an exception, or returning random results, or any other “bad” behavior. And it can call "=" in whatever manner makes sense. But note that only the results of Find, Reverse_Find, and List "=" are unspecified; other subprograms are not allowed to break if "=" is bad (they aren't expected to use "="). 55.a/2

{*AI95-00302-03*} The type List is used to represent lists. The type List needs finalization (see 7.6). 56/2

{*AI95-00302-03*} Empty_List represents the empty List object. It has a length of 0. If an object of type List is not otherwise initialized, it is initialized to the same value as Empty_List. 57/2

{*AI95-00302-03*} No_Element represents a cursor that designates no element. If an object of type Cursor is not otherwise initialized, it is initialized to the same value as No_Element. 58/2

{*AI95-00302-03*} {*AI12-0434-1*} The primitive "=" operator for type Cursor returns True if both cursors are No_Element, or designate the same element in the same container. 59/5

To be honest: {*AI12-0434-1*} “The primitive "=" operator” is the one with two parameters of type Cursor which returns Boolean. We're not talking about some other (hidden) primitive function named "=". 59.a/5

60/2 {*AI95-00302-03*} Execution of the default implementation of the Input, Output, Read, or Write attribute of type Cursor raises Program_Error.

60.a/2 **Reason:** A cursor will probably be implemented in terms of one or more access values, and the effects of streaming access values is unspecified. Rather than letting the user stream junk by accident, we mandate that streaming of cursors raise Program_Error by default. The attributes can always be specified if there is a need to support streaming.

60.1/5 {*AI05-0001-1*} {*AI05-0262-1*} {*AI12-0437-1*} List'Write for a List object *L* writes Length(*L*) elements of the list to the stream. It may also write additional information about the list.

60.2/3 {*AI05-0001-1*} {*AI05-0262-1*} List'Read reads the representation of a list from the stream, and assigns to *Item* a list with the same length and elements as was written by List'Write.

60.b/3 **Ramification:** Streaming more elements than the container length is wrong. For implementation implications of this rule, see the Implementation Note in A.18.2.

61/5 {*AI95-00302-03*} {*AI12-0111-1*} {*AI12-0112-1*} [Some operations check for “tampering with cursors” of a container because they depend on the set of elements of the container remaining constant, and others check for “tampering with elements” of a container because they depend on elements of the container not being replaced.] When tampering with cursors is *prohibited* for a particular list object *L*, Program_Error is propagated by the finalization of *L*[, as well as by a call that passes *L* to certain of the operations of this package, as indicated by the precondition of such an operation]. Similarly, when tampering with elements is *prohibited* for *L*, Program_Error is propagated by a call that passes *L* to certain of the other operations of this package, as indicated by the precondition of such an operation.

Paragraphs 62 through 69 are removed as preconditions now describe these rules.

65.a.1/3 **Ramification:** We don't need to explicitly mention assignment_statement, because that finalizes the target object as part of the operation, and finalization of an object is already defined as tampering with cursors.

69.2/5
```
function Has_Element (Position : Cursor) return Boolean
   with Nonblocking, Global => in all, Use_Formal => null;
```

69.3/3 {*AI05-0212-1*} Returns True if Position designates an element, and returns False otherwise.

69.c/3 **To be honest:** {*AI05-0005-1*} {*AI05-0212-1*} This function might not detect cursors that designate deleted elements; such cursors are invalid (see below) and the result of calling Has_Element with an invalid cursor is unspecified (but not erroneous).

69.4/5
```
function Has_Element (Container : List; Position : Cursor)
   return Boolean
   with Nonblocking, Global => null, Use_Formal => null;
```

69.5/5 {*AI12-0112-1*} Returns True if Position designates an element in Container, and returns False otherwise.

69.d/5 **Ramification:** If Position is No_Element, Has_Element returns False.

70/2
```
function "=" (Left, Right : List) return Boolean;
```

71/3 {*AI95-00302-03*} {*AI05-0264-1*} If Left and Right denote the same list object, then the function returns True. If Left and Right have different lengths, then the function returns False. Otherwise, it compares each element in Left to the corresponding element in Right using the generic formal equality operator. If any such comparison returns False, the function returns False; otherwise, it returns True. Any exception raised during evaluation of element equality is propagated.

71.a/2 **Implementation Note:** This wording describes the canonical semantics. However, the order and number of calls on the formal equality function is unspecified for all of the operations that use it in this package, so an implementation can call it as many or as few times as it needs to get the correct answer. Specifically, there is no requirement to call the formal equality additional times once the answer has been determined.

```
function Tampering_With_Cursors_Prohibited                                    71.1/5
   (Container : List) return Boolean
   with Nonblocking, Global => null, Use_Formal => null;
```

{*AI12-0112-1*} Returns True if tampering with cursors or tampering with elements is currently prohibited for Container, and returns False otherwise. 71.2/5

Reason: {*AI12-0112-1*} Prohibiting tampering with elements also needs to prohibit tampering with cursors, as deleting an element is similar to replacing it. 71.b/5

Implementation Note: {*AI12-0112-1*} Various contracts elsewhere in this specification require that this function be implemented with synchronized data. Moreover, it is possible for tampering to be prohibited by multiple operations (sequentially or in parallel). Therefore, tampering needs to be implemented with an atomic or protected counter. The counter is initialized to zero, and is incremented when tampering is prohibited, and decremented when leaving an area that prohibited tampering. Function Tampering_With_Cursors_Prohibited returns True if the counter is nonzero. (Note that any case where the result is not well-defined for one task is incorrect use of shared variables and would be erroneous by the rules of 9.10, so no special protection is needed to read the counter.) 71.c/5

```
function Tampering_With_Elements_Prohibited                                   71.3/5
   (Container : List) return Boolean
   with Nonblocking, Global => null, Use_Formal => null;
```

{*AI12-0112-1*} Always returns False[, regardless of whether tampering with elements is prohibited]. 71.4/5

Reason: {*AI12-0111-1*} A definite element cannot change size, so we allow operations that tamper with elements even when tampering with elements is prohibited. That's not true for the indefinite containers, which is why this kind of tampering exists. 71.d/5

```
function Length (Container : List) return Count_Type                          72/5
   with Nonblocking, Global => null, Use_Formal => null;
```

{*AI95-00302-03*} Returns the number of elements in Container. 73/2

```
function Is_Empty (Container : List) return Boolean                           74/5
   with Nonblocking, Global => null, Use_Formal => null,
        Post => Is_Empty'Result = (Length (Container) = 0);
```

{*AI95-00302-03*} {*AI12-0112-1*} Returns True if Container is empty. 75/5

```
procedure Clear (Container : in out List)                                     76/5
   with Pre  => not Tampering_With_Cursors_Prohibited (Container)
                    or else raise Program_Error,
        Post => Length (Container) = 0;
```

{*AI95-00302-03*} Removes all the elements from Container. 77/2

```
function Element (Position : Cursor) return Element_Type                      78/5
   with Pre  => Position /= No_Element or else raise Constraint_Error,
        Nonblocking, Global => in all, Use_Formal => Element_Type;
```

{*AI95-00302-03*} {*AI12-0112-1*} Element returns the element designated by Position. 79/5

```
function Element (Container : List;                                           79.1/5
                  Position  : Cursor) return Element_Type
   with Pre => (Position /= No_Element or else
                   raise Constraint_Error) and then
               (Has_Element (Container, Position)
                   or else raise Program_Error),
        Nonblocking, Global => null, Use_Formal => Element_Type;
```

{*AI12-0112-1*} Element returns the element designated by Position in Container. 79.2/5

80/5
```
procedure Replace_Element (Container : in out List;
                           Position  : in     Cursor;
                           New_item  : in     Element_Type)
   with Pre  => (not Tampering_With_Elements_Prohibited (Container)
                    or else raise Program_Error) and then
                 (Position /= No_Element
                    or else raise Constraint_Error) and then
                 (Has_Element (Container, Position)
                    or else raise Program_Error);
```

81/5 {*AI95-00302-03*} {*AI05-0264-1*} {*AI12-0112-1*} {*AI12-0196-1*} Replace_Element assigns the value New_Item to the element designated by Position. For the purposes of determining whether the parameters overlap in a call to Replace_Element, the Container parameter is not considered to overlap with any object [(including itself)].

82/5
```
procedure Query_Element
  (Position : in Cursor;
   Process  : not null access procedure (Element : in Element_Type))
   with Pre  => Position /= No_Element or else raise Constraint_Error,
        Global => in all;
```

83/5 {*AI95-00302-03*} {*AI05-0021-1*} {*AI05-0265-1*} {*AI12-0112-1*} Query_Element calls Process.**all** with the element designated by Position as the argument. Tampering with the elements of the list that contains the element designated by Position is prohibited during the execution of the call on Process.**all**. Any exception raised by Process.**all** is propagated.

83.1/5
```
procedure Query_Element
  (Container : in List;
   Position  : in Cursor;
   Process   : not null access procedure (Element : in Element_Type))
   with Pre  => (Position /= No_Element
                    or else raise Constraint_Error) and then
                (Has_Element (Container, Position)
                    or else raise Program_Error);
```

83.2/5 {*AI12-0112-1*} Query_Element calls Process.**all** with the element designated by Position as the argument. Tampering with the elements of Container is prohibited during the execution of the call on Process.**all**. Any exception raised by Process.**all** is propagated.

84/5
```
procedure Update_Element
  (Container : in out List;
   Position  : in     Cursor;
   Process   : not null access procedure
                  (Element : in out Element_Type))
   with Pre  => (Position /= No_Element
                    or else raise Constraint_Error) and then
                (Has_Element (Container, Position)
                    or else raise Program_Error);
```

85/5 {*AI95-00302-03*} {*AI05-0264-1*} {*AI05-0265-1*} {*AI12-0112-1*} Update_Element calls Process.**all** with the element designated by Position as the argument. Tampering with the elements of Container is prohibited during the execution of the call on Process.**all**. Any exception raised by Process.**all** is propagated.

86/2 If Element_Type is unconstrained and definite, then the actual Element parameter of Process.**all** shall be unconstrained.

86.a/2 **Ramification:** This means that the elements cannot be directly allocated from the heap; it must be possible to change the discriminants of the element in place.

```
{AI12-0112-1} type Constant_Reference_Type                                    86.1/5
      (Element : not null access constant Element_Type) is private
   with Implicit_Dereference => Element,
        Nonblocking, Global => in out synchronized,
        Default_Initial_Condition => (raise Program_Error);

{AI12-0112-1} type Reference_Type (Element : not null access Element_Type) is  86.2/5
private
   with Implicit_Dereference => Element,
        Nonblocking, Global => in out synchronized,
        Default_Initial_Condition => (raise Program_Error);
```

{*AI05-0212-1*} The types Constant_Reference_Type and Reference_Type need finalization. 86.3/3

This paragraph was deleted.{*AI12-0112-1*} 86.4/5

Reason: It is expected that Reference_Type (and Constant_Reference_Type) will be a controlled type, for which finalization will have some action to terminate the tampering check for the associated container. If the object is created by default, however, there is no associated container. Since this is useless, and supporting this case would take extra work, we define it to raise an exception. 86.b/3

```
{AI12-0112-1} function Constant_Reference (Container : aliased in List;      86.5/5
                           Position  : in Cursor)
   return Constant_Reference_Type
   with Pre  => (Position /= No_Element or else
                    raise Constraint_Error) and then
                 (Has_Element (Container, Position) or else
                    raise Program_Error),
        Post   => Tampering_With_Cursors_Prohibited (Container),
        Nonblocking, Global => null, Use_Formal => null;
```

{*AI05-0212-1*} {*AI05-0269-1*} This function (combined with the Constant_Indexing and Implicit_Dereference aspects) provides a convenient way to gain read access to an individual element of a list given a cursor. 86.6/3

{*AI05-0212-1*} {*AI05-0265-1*} {*AI12-0112-1*} Constant_Reference returns an object whose discriminant is an access value that designates the element designated by Position. Tampering with the elements of Container is prohibited while the object returned by Constant_Reference exists and has not been finalized. 86.7/5

```
{AI12-0112-1} function Reference (Container : aliased in out List;           86.8/5
                     Position  : in Cursor)
   return Reference_Type
   with Pre  => (Position /= No_Element or else
                    raise Constraint_Error) and then
                 (Has_Element (Container, Position) or else
                    raise Program_Error),
        Post   => Tampering_With_Cursors_Prohibited (Container),
        Nonblocking, Global => null, Use_Formal => null;
```

{*AI05-0212-1*} {*AI05-0269-1*} This function (combined with the Variable_Indexing and Implicit_Dereference aspects) provides a convenient way to gain read and write access to an individual element of a list given a cursor. 86.9/3

{*AI05-0212-1*} {*AI05-0265-1*} {*AI12-0112-1*} Reference returns an object whose discriminant is an access value that designates the element designated by Position. Tampering with the elements of Container is prohibited while the object returned by Reference exists and has not been finalized. 86.10/5

86.11/5
```
{AI12-0112-1} procedure Assign (Target : in out List; Source : in List)
   with Pre  => not Tampering_With_Cursors_Prohibited (Target)
                    or else raise Program_Error,
        Post => Length (Source) = Length (Target);
```

86.12/3 {*AI05-0001-1*} {*AI05-0248-1*} If Target denotes the same object as Source, the operation has no effect. Otherwise, the elements of Source are copied to Target as for an assignment_statement assigning Source to Target.

86.c/3 **Discussion:** {*AI05-0005-1*} This routine exists for compatibility with the bounded list container. For an unbounded list, `Assign(A, B)` and `A := B` behave identically. For a bounded list, := will raise an exception if the container capacities are different, while Assign will not raise an exception if there is enough room in the target.

86.13/5
```
{AI12-0112-1} function Copy (Source : List)
   return List
   with Post =>
           Length (Copy'Result) = Length (Source) and then
           not Tampering_With_Elements_Prohibited (Copy'Result) and then
           not Tampering_With_Cursors_Prohibited (Copy'Result);
```

86.14/3 {*AI05-0001-1*} Returns a list whose elements match the elements of Source.

87/5
```
{AI12-0112-1} procedure Move (Target : in out List;
                              Source : in out List)
   with Pre  => (not Tampering_With_Cursors_Prohibited (Target)
                     or else raise Program_Error) and then
                (not Tampering_With_Cursors_Prohibited (Source)
                     or else raise Program_Error),
        Post => (if not Target'Has_Same_Storage (Source) then
                     Length (Target) = Length (Source'Old) and then
                     Length (Source) = 0);
```

88/3 {*AI95-00302-03*} {*AI05-0001-1*} {*AI05-0248-1*} {*AI05-0262-1*} If Target denotes the same object as Source, then the operation has no effect. Otherwise, the operation is equivalent to Assign (Target, Source) followed by Clear (Source).

89/5
```
procedure Insert (Container : in out List;
                  Before    : in     Cursor;
                  New_Item  : in     Element_Type;
                  Count     : in     Count_Type := 1)
   with Pre  => (not Tampering_With_Cursors_Prohibited (Container)
                     or else raise Program_Error) and then
                (Before = No_Element or else
                 Has_Element (Container, Before)
                     or else raise Program_Error) and then
                (Length (Container) <= Count_Type'Last - Count
                     or else raise Constraint_Error),
        Post => Length (Container)'Old + Count = Length (Container);
```

90/5 {*AI95-00302-03*} {*AI12-0112-1*} Insert inserts Count copies of New_Item prior to the element designated by Before. If Before equals No_Element, the new elements are inserted after the last node (if any). Any exception raised during allocation of internal storage is propagated, and Container is not modified.

90.a/2 **Ramification:** The check on Before checks that the cursor does not belong to some other Container. This check implies that a reference to the container is included in the cursor value. This wording is not meant to require detection of dangling cursors; such cursors are defined to be invalid, which means that execution is erroneous, and any result is allowed (including not raising an exception).

```
procedure Insert (Container : in out List;                                    91/5
                  Before    : in     Cursor;
                  New_Item  : in     Element_Type;
                  Position  :    out Cursor;

                    or else raise Program_Error) and then
                 (Length (Container) <= Count_Type'Last - 1
                    or else raise Constraint_Error),
        Post => Length (Container)'Old + 1 = Length (Container);
```

98.2/5 {*AI12-0391-1*} Equivalent to Insert (Container, No_Element, New_Item, 1).

99/5
```
procedure Delete (Container : in out List;
                  Position  : in out Cursor;
                  Count     : in     Count_Type := 1)
   with Pre  => (not Tampering_With_Cursors_Prohibited (Container)
                    or else raise Program_Error) and then
                 (Position /= No_Element
                    or else raise Constraint_Error) and then
                 (Has_Element (Container, Position)
                    or else raise Program_Error),
        Post => Length (Container)'Old - Count <= Length (Container)
                and then Position = No_Element;
```

100/5 {*AI95-00302-03*} {*AI05-0264-1*} {*AI12-0112-1*} Delete removes (from Container) Count elements starting at the element designated by Position (or all of the elements starting at Position if there are fewer than Count elements starting at Position). Finally, Position is set to No_Element.

101/5
```
{AI12-0112-1} procedure Delete_First (Container : in out List;
                       Count     : in     Count_Type := 1)
   with Pre  => not Tampering_With_Cursors_Prohibited (Container)
                    or else raise Program_Error,
        Post => Length (Container)'Old - Count <= Length (Container);
```

102/3 {*AI95-00302-03*} {*AI05-0021-1*} If Length (Container) <= Count, then Delete_First is equivalent to Clear (Container). Otherwise, it removes the first Count nodes from Container.

103/5
```
{AI12-0112-1} procedure Delete_Last (Container : in out List;
                      Count     : in     Count_Type := 1)
   with Pre  => not Tampering_With_Cursors_Prohibited (Container)
                    or else raise Program_Error,
        Post => Length (Container)'Old - Count <= Length (Container);
```

104/3 {*AI95-00302-03*} {*AI05-0264-1*} If Length (Container) <= Count, then Delete_Last is equivalent to Clear (Container). Otherwise, it removes the last Count nodes from Container.

105/5
```
{AI12-0112-1} procedure Reverse_Elements (Container : in out List)
   with Pre  => not Tampering_With_Cursors_Prohibited (Container)
                    or else raise Program_Error;
```

106/2 {*AI95-00302-03*} Reorders the elements of Container in reverse order.

106.a/2 **Discussion:** Unlike the similar routine for a vector, elements should not be copied; rather, the nodes should be exchanged. Cursors are expected to reference the same elements afterwards.

107/5
```
procedure Swap (Container : in out List;
                I, J      : in     Cursor)
   with Pre  => (not Tampering_With_Elements_Prohibited (Container)
                    or else raise Program_Error) and then
                 (I /= No_Element or else Constraint_Error) and then
                 (J /= No_Element or else Constraint_Error) and then
                 (Has_Element (Container, I)
                    or else raise Program_Error) and then
                 (Has_Element (Container, J)
                    or else raise Program_Error);
```

108/5 {*AI95-00302-03*} {*AI12-0112-1*} Swap exchanges the values of the elements designated by I and J.

Ramification: After a call to Swap, I designates the element value previously designated by J, and J designates the element value previously designated by I. The cursors do not become ambiguous from this operation. 108.a/2

To be honest: The implementation is not required to actually copy the elements if it can do the swap some other way. But it is allowed to copy the elements if needed. 108.b/2

```
procedure Swap_Links (Container : in out List;                                    109/5
                      I, J      : in     Cursor)
   with Pre  => (not Tampering_With_Elements_Prohibited (Container)
                    or else raise Program_Error) and then
                 (I /= No_Element or else Constraint_Error) and then
                 (J /= No_Element or else Constraint_Error) and then
                 (Has_Element (Container, I)
                    or else raise Program_Error) and then
                 (Has_Element (Container, J)
                    or else raise Program_Error);
```

{*AI95-00302-03*} {*AI12-0112-1*} Swap_Links exchanges the nodes designated by I and J. 110/5

Ramification: Unlike Swap, this exchanges the nodes, not the elements. No copying is performed. I and J designate the same elements after this call as they did before it. This operation can provide better performance than Swap if the element size is large. 110.a/2

```
procedure Splice (Target   : in out List;                                         111/5
                  Before   : in     Cursor;
                  Source   : in out List)
   with Pre  => (not Tampering_With_Cursors_Prohibited (Target)
                    or else raise Program_Error) and then
                 (not Tampering_With_Cursors_Prohibited (Source)
                    or else raise Program_Error) and then
                 (Before = No_Element or else
                  Has_Element (Target, Before)
                    or else raise Program_Error) and then
                 (Target'Has_Same_Storage (Source) or else
                  Length (Target) <= Count_Type'Last - Length (Source)
                    or else raise Constraint_Error),
        Post => (if not Target'Has_Same_Storage (Source) then
                    (declare
                       Result_Length : constant Count_Type :=
                          Length (Source)'Old + Length (Target)'Old;
                     begin
                       Length (Source) = 0 and then
                       Length (Target) = Result_Length));
```

{*AI95-00302-03*} {*AI12-0112-1*} If Source denotes the same object as Target, the operation has no effect. Otherwise, Splice reorders elements such that they are removed from Source and moved to Target, immediately prior to Before. If Before equals No_Element, the nodes of Source are spliced after the last node of Target. 112/5

113/5
```
procedure Splice (Target   : in out List;
                  Before   : in     Cursor;
                  Source   : in out List;
                  Position : in out Cursor)
   with Pre  => (not Tampering_With_Cursors_Prohibited (Target)
                   or else raise Program_Error) and then
                (not Tampering_With_Cursors_Prohibited (Source)
                   or else raise Program_Error) and then
                (Position /= No_Element
                   or else raise Constraint_Error) and then
                (Has_Element (Source, Position)
                   or else raise Program_Error) and then
                (Before = No_Element or else
                 Has_Element (Target, Before)
                   or else raise Program_Error) and then
                (Target'Has_Same_Storage (Source) or else
                 Length (Target) <= Count_Type'Last - 1
                   or else raise Constraint_Error),
        Post => (declare
                   Org_Target_Length : constant Count_Type :=
                      Length (Target)'Old;
                   Org_Source_Length : constant Count_Type :=
                      Length (Source)'Old;
                 begin
                    (if Target'Has_Same_Storage (Source) then
                        Position = Position'Old
                     else Length (Source) = Org_Source_Length - 1 and then
                        Length (Target) = Org_Target_Length + 1 and then
                        Has_Element (Target, Position)));
```

114/5 {*AI95-00302-03*} {*AI05-0264-1*} {*AI12-0112-1*} If Source denotes the same object as Target, then there is no effect if Position equals Before, else the element designated by Position is moved immediately prior to Before, or, if Before equals No_Element, after the last element. Otherwise, the element designated by Position is removed from Source and moved to Target, immediately prior to Before, or, if Before equals No_Element, after the last element of Target. Position is updated to represent an element in Target.

114.a/2 **Ramification:** If Source is the same as Target, and Position = Before, or Next(Position) = Before, Splice has no effect, as the element does not have to move to meet the postcondition.

115/5
```
procedure Splice (Container: in out List;
                  Before   : in     Cursor;
                  Position : in     Cursor)
   with Pre  => (not Tampering_With_Cursors_Prohibited (Container)
                   or else raise Program_Error) and then
                (Position /= No_Element
                   or else raise Constraint_Error) and then
                (Has_Element (Container, Position)
                   or else raise Program_Error) and then
                (Before = No_Element or else
                 Has_Element (Container, Before)
                   or else raise Program_Error),
        Post =>  Length (Container) = Length (Container)'Old;
```

116/5 {*AI95-00302-03*} {*AI05-0264-1*} {*AI12-0112-1*} If Position equals Before there is no effect. Otherwise, the element designated by Position is moved immediately prior to Before, or, if Before equals No_Element, after the last element.

```
{AI12-0112-1} procedure Iterate                                             141/5
  (Container : in List;
   Process   : not null access procedure (Position : in Cursor))
   with Allows_Exit;
```

{*AI95-00302-03*} {*AI05-0265-1*} Iterate calls Process.**all** with a cursor that designates each node in Container, starting with the first node and moving the cursor as per the Next function. Tampering with the cursors of Container is prohibited during the execution of a call on Process.**all**. Any exception raised by Process.**all** is propagated. 142/3

Implementation Note: The purpose of the tamper with cursors check is to prevent erroneous execution from the Position parameter of Process.**all** becoming invalid. This check takes place when the operations that tamper with the cursors of the container are called. The check cannot be made later (say in the body of Iterate), because that could cause the Position cursor to be invalid and potentially cause execution to become erroneous -- defeating the purpose of the check. 142.a/2

See Iterate for vectors (A.18.2) for a suggested implementation of the check. 142.b/2

```
{AI12-0112-1} procedure Reverse_Iterate                                     143/5
  (Container : in List;
   Process   : not null access procedure (Position : in Cursor))
   with Allows_Exit;
```

{*AI95-00302-03*} {*AI05-0212-1*} Iterates over the nodes in Container as per procedure Iterate, except that elements are traversed in reverse order, starting with the last node and moving the cursor as per the Previous function. 144/3

```
{AI12-0112-1} {AI12-0266-1} function Iterate (Container : in List)          144.1/5
   return List_Iterator_Interfaces.Parallel_Reversible_Iterator'Class
   with Post   => Tampering_With_Cursors_Prohibited (Container);
```

{*AI05-0212-1*} {*AI05-0265-1*} {*AI05-0269-1*} {*AI12-0266-1*} Iterate returns an iterator object (see 5.5.1) that will generate a value for a loop parameter (see 5.5.2) designating each node in Container, starting with the first node and moving the cursor as per the Next function when used as a forward iterator, and starting with the last node and moving the cursor as per the Previous function when used as a reverse iterator, and processing all nodes concurrently when used as a parallel iterator. Tampering with the cursors of Container is prohibited while the iterator object exists (in particular, in the sequence_of_statements of the loop_statement whose iterator_specification denotes this object). The iterator object needs finalization. 144.2/5

144.3/5
```
function Iterate (Container : in List; Start : in Cursor)
   return List_Iterator_Interfaces.Reversible_Iterator'Class
   with Pre    => (Start /= No_Element
                      or else raise Constraint_Error) and then
                  (Has_Element (Container, Start)
                      or else raise Program_Error),
        Post   => Tampering_With_Cursors_Prohibited (Container);
```

144.4/5 {*AI05-0212-1*} {*AI05-0262-1*} {*AI05-0265-1*} {*AI05-0269-1*} {*AI12-0112-1*} Iterate returns a reversible iterator object (see 5.5.1) that will generate a value for a loop parameter (see 5.5.2) designating each node in Container, starting with the node designated by Start and moving the cursor as per the Next function when used as a forward iterator, or moving the cursor as per the Previous function when used as a reverse iterator. Tampering with the cursors of Container is prohibited while the iterator object exists (in particular, in the sequence_of_statements of the loop_statement whose iterator_specification denotes this object). The iterator object needs finalization.

144.a/3 **Discussion:** Exits are allowed from the loops created using the iterator objects. In particular, to stop the iteration at a particular cursor, just add

144.b/3
```
exit when Cur = Stop;
```

144.c/3 in the body of the loop (assuming that `Cur` is the loop parameter and `Stop` is the cursor that you want to stop at).

145/3 {*AI05-0044-1*} {*AI05-0262-1*} The actual function for the generic formal function "<" of Generic_Sorting is expected to return the same value each time it is called with a particular pair of element values. It should define a strict weak ordering relationship (see A.18); it should not modify Container. If the actual for "<" behaves in some other manner, the behavior of the subprograms of Generic_Sorting are unspecified. The number of times the subprograms of Generic_Sorting call "<" is unspecified.

146/2
```
function Is_Sorted (Container : List) return Boolean;
```

147/2 {*AI95-00302-03*} Returns True if the elements are sorted smallest first as determined by the generic formal "<" operator; otherwise, Is_Sorted returns False. Any exception raised during evaluation of "<" is propagated.

148/5
```
{AI12-0112-1} procedure Sort (Container : in out List)
   with Pre  => not Tampering_With_Cursors_Prohibited (Container)
                    or else raise Program_Error;
```

149/2 {*AI95-00302-03*} Reorders the nodes of Container such that the elements are sorted smallest first as determined by the generic formal "<" operator provided. The sort is stable. Any exception raised during evaluation of "<" is propagated.

149.a/2 **Ramification:** Unlike array sorts, we do require stable sorts here. That's because algorithms in the merge sort family (as described by Knuth) can be both fast and stable. Such sorts use the extra memory as offered by the links to provide better performance.

149.b/2 Note that list sorts never copy elements; it is the nodes, not the elements, that are reordered.

```
procedure Merge (Target  : in out List;                                    150/5
                 Source  : in out List)
   with Pre  => (not Tampering_With_Cursors_Prohibited (Target)
                    or else raise Program_Error) and then
                 (not Tampering_With_Elements_Prohibited (Source)
                    or else raise Program_Error) and then
                 (Length (Target) <= Count_Type'Last - Length (Source)
                    or else raise Constraint_Error) and then
                 ((Length (Source) = 0 or else
                    not Target'Has_Same_Storage (Source))
                    or else raise Constraint_Error),
        Post => (declare
                    Result_Length : constant Count_Type :=
                       Length (Source)'Old + Length (Target)'Old;
                 begin
                    (Length (Source) = 0 and then
                     Length (Target) = Result_Length));
```

{*AI95-00302-03*} {*AI05-0021-1*} {*AI12-0112-1*} Merge removes elements from Source and inserts them into Target; afterwards, Target contains the union of the elements that were initially in Source and Target; Source is left empty. If Target and Source are initially sorted smallest first, then Target is ordered smallest first as determined by the generic formal "<" operator; otherwise, the order of elements in Target is unspecified. Any exception raised during evaluation of "<" is propagated. 151/5

Ramification: It is a bounded error if either of the lists is unsorted, see below. The bounded error can be recovered by sorting Target after the merge call, or the lists can be pretested with Is_Sorted. 151.a/2

{*AI12-0111-1*} The nested package Doubly_Linked_Lists.Stable provides a type Stable.List that represents a *stable* list, which is one that cannot grow and shrink. Such a list can be created by calling the Copy function, or by establishing a *stabilized view* of an ordinary list. 151.1/5

{*AI12-0111-1*} The subprograms of package Containers.Doubly_Linked_Lists that have a parameter or result of type List are included in the nested package Stable with the same specification, except that the following are omitted: 151.2/5

Tampering_With_Cursors_Prohibited, Tampering_With_Elements_Prohibited, Assign, Move, Insert, Append, Prepend, Clear, Delete, Delete_First, Delete_Last, Splice, Swap_Links, and Reverse_Elements 151.3/5

Ramification: The names List and Cursor mean the types declared in the nested package in these subprogram specifications. 151.a.1/5

Reason: The omitted routines are those that tamper with cursors or elements (or test that state). The model is that it is impossible to tamper with cursors or elements of a stable view since no such operations are included. Thus tampering checks are not needed for a stable view, and we omit the operations associated with those checks. 151.a.2/5

The Generic_Sorting generic is omitted entirely, as only function Is_Sorting does not tamper with cursors. It isn't useful enough by itself to include. 151.a.3/5

{*AI12-0111-1*} The operations of this package are equivalent to those for ordinary lists, except that the calls to Tampering_With_Cursors_Prohibited and Tampering_With_Elements_Prohibited that occur in preconditions are replaced by False, and any that occur in postconditions are replaced by True. 151.4/5

{*AI12-0111-1*} {*AI12-0439-1*} If a stable list is declared with the Base discriminant designating a pre-existing ordinary list, the stable list represents a stabilized view of the underlying ordinary list, and any operation on the stable list is reflected on the underlying ordinary list. While a stabilized view exists, any operation that tampers with elements performed on the underlying list is prohibited. The finalization of a stable list that provides such a view removes this restriction on the underlying ordinary list [(though some other restriction can exist due to other concurrent iterations or stabilized views)]. 151.5/5

151.6/5 {*AI12-0111-1*} {*AI12-0438-1*} If a stable list is declared without specifying Base, the object is necessarily initialized. The initializing expression of the stable list, [typically a call on Copy], determines the Length of the list. The Length of a stable list never changes after initialization.

151.b/5 **Proof:** {*AI12-0438-1*} Initialization is required as the type is indefinite, see 3.3.1.

Bounded (Run-Time) Errors

152/2 {*AI95-00302-03*} Calling Merge in an instance of Generic_Sorting with either Source or Target not ordered smallest first using the provided generic formal "<" operator is a bounded error. Either Program_Error is raised after Target is updated as described for Merge, or the operation works as defined.

152.1/3 {*AI05-0022-1*} {*AI05-0248-1*} It is a bounded error for the actual function associated with a generic formal subprogram, when called as part of an operation of this package, to tamper with elements of any List parameter of the operation. Either Program_Error is raised, or the operation works as defined on the value of the List either prior to, or subsequent to, some or all of the modifications to the List.

152.2/3 {*AI05-0027-1*} It is a bounded error to call any subprogram declared in the visible part of Containers.Doubly_Linked_Lists when the associated container has been finalized. If the operation takes Container as an **in out** parameter, then it raises Constraint_Error or Program_Error. Otherwise, the operation either proceeds as it would for an empty container, or it raises Constraint_Error or Program_Error.

Erroneous Execution

153/2 {*AI95-00302-03*} A Cursor value is *invalid* if any of the following have occurred since it was created:

154/2 • The list that contains the element it designates has been finalized;

154.1/3 • {*AI05-0160-1*} The list that contains the element it designates has been used as the Target of a call to Assign, or as the target of an assignment_statement;

155/2 • [The list that contains the element it designates has been used as the Source or Target of a call to Move;] or

155.a/3 **Proof:** {*AI05-0001-1*} Move has been reworded in terms of Assign and Clear, which are covered by other bullets, so this text is redundant.

156/3 • {*AI05-0160-1*} {*AI05-0262-1*} The element it designates has been removed from the list that previously contained the element.

156.a/3 **To be honest:** {*AI05-0160-1*} The cursor modified by the four parameter Splice is not invalid, even though the element it designates has been removed from the source list, because that cursor has been modified to designate that element in the target list – the cursor no longer designates an element in the source list.

156.b/3 **Ramification:** {*AI05-0160-1*} This can happen directly via calls to Delete, Delete_Last, Clear, Splice with a Source parameter, and Merge; and indirectly via calls to Delete_First, Assign, and Move.

157/2 {*AI95-00302-03*} The result of "=" or Has_Element is unspecified if it is called with an invalid cursor parameter. Execution is erroneous if any other subprogram declared in Containers.Doubly_Linked_Lists is called with an invalid cursor parameter.

157.a/2 **Discussion:** The list above is intended to be exhaustive. In other cases, a cursor value continues to designate its original element. For instance, cursor values survive the insertion and deletion of other nodes.

157.b/2 While it is possible to check for these cases, in many cases the overhead necessary to make the check is substantial in time or space. Implementations are encouraged to check for as many of these cases as possible and raise Program_Error if detected.

157.1/3 {*AI05-0212-1*} Execution is erroneous if the list associated with the result of a call to Reference or Constant_Reference is finalized before the result object returned by the call to Reference or Constant_Reference is finalized.

Reason: Each object of Reference_Type and Constant_Reference_Type probably contains some reference to the originating container. If that container is prematurely finalized (which is only possible via Unchecked_Deallocation, as accessibility checks prevent passing a container to Reference that will not live as long as the result), the finalization of the object of Reference_Type will try to access a nonexistent object. This is a normal case of a dangling pointer created by Unchecked_Deallocation; we have to explicitly mention it here as the pointer in question is not visible in the specification of the type. (This is the same reason we have to say this for invalid cursors.) 157.c/3

Implementation Requirements

{*AI95-00302-03*} {*AI12-0437-1*} No storage associated with a doubly-linked list object shall be lost upon assignment or scope exit. 158/5

{*AI95-00302-03*} {*AI05-0262-1*} The execution of an assignment_statement for a list shall have the effect of copying the elements from the source list object to the target list object and changing the length of the target object to that of the source object. 159/3

Implementation Note: {*AI05-0298-1*} An assignment of a List is a "deep" copy; that is the elements are copied as well as the data structures. We say "effect of" in order to allow the implementation to avoid copying elements immediately if it wishes. For instance, an implementation that avoided copying until one of the containers is modified would be allowed. (Note that this implementation would require care, see A.18.2 for more.) 159.a/3

Implementation Advice

{*AI95-00302-03*} Containers.Doubly_Linked_Lists should be implemented similarly to a linked list. In particular, if *N* is the length of a list, then the worst-case time complexity of Element, Insert with Count=1, and Delete with Count=1 should be *O*(log *N*). 160/2

Implementation Advice: The worst-case time complexity of Element, Insert with Count=1, and Delete with Count=1 for Containers.Doubly_Linked_Lists should be *O*(log *N*). 160.a/2

Reason: We do not mean to overly constrain implementation strategies here. However, it is important for portability that the performance of large containers has roughly the same factors on different implementations. If a program is moved to an implementation that takes *O*(*N*) time to access elements, that program could be unusable when the lists are large. We allow *O*(log *N*) access because the proportionality constant and caching effects are likely to be larger than the log factor, and we don't want to discourage innovative implementations. 160.b/2

{*AI95-00302-03*} The worst-case time complexity of a call on procedure Sort of an instance of Containers.Doubly_Linked_Lists.Generic_Sorting should be *O*(*N***2), and the average time complexity should be better than *O*(*N***2). 161/2

Implementation Advice: A call on procedure Sort of an instance of Containers.Doubly_Linked_Lists.Generic_Sorting should have an average time complexity better than *O*(*N***2) and worst case no worse than *O*(*N***2). 161.a/2

Ramification: In other words, we're requiring the use of a better than *O*(*N***2) sorting algorithm, such as Quicksort. No bubble sorts allowed! 161.b/2

{*AI95-00302-03*} Move should not copy elements, and should minimize copying of internal data structures. 162/2

Implementation Advice: Containers.Doubly_Linked_Lists.Move should not copy elements, and should minimize copying of internal data structures. 162.a/2

Implementation Note: Usually that can be accomplished simply by moving the pointer(s) to the internal data structures from the Source container to the Target container. 162.b/2

{*AI95-00302-03*} If an exception is propagated from a list operation, no storage should be lost, nor any elements removed from a list unless specified by the operation. 163/2

Implementation Advice: If an exception is propagated from a list operation, no storage should be lost, nor any elements removed from a list unless specified by the operation. 163.a/2

Reason: This is important so that programs can recover from errors. But we don't want to require heroic efforts, so we just require documentation of cases where this can't be accomplished. 163.b/2

NOTE {*AI95-00302-03*} {*AI12-0442-1*} Sorting a list never copies elements, and is a stable sort (equal elements remain in the original order). This is different than sorting an array or vector, which will often copy elements, and hence is probably not a stable sort. 164/5

Extensions to Ada 95

164.a/2 {*AI95-00302-03*} The generic package Containers.Doubly_Linked_Lists is new.

Inconsistencies With Ada 2005

164.b/3 {*AI05-0248-1*} {*AI05-0257-1*} **Correction:** The Insert versions that return a Position parameter are now defined to return Position = Before if Count = 0. This was unspecified for Ada 2005; so this will only be inconsistent if an implementation did something else and a program depended on that something else — this should be very rare.

Incompatibilities With Ada 2005

164.c/3 {*AI05-0001-1*} Subprograms Assign and Copy are added to Containers.Doubly_Linked_Lists. If an instance of Containers.Doubly_Linked_Lists is referenced in a use_clause, and an entity *E* with the same defining_identifier as a new entity in Containers.Doubly_Linked_Lists is defined in a package that is also referenced in a use_clause, the entity *E* may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur.

Extensions to Ada 2005

164.d/3 {*AI05-0212-1*} Added iterator, reference, and indexing support to make list containers more convenient to use.

Wording Changes from Ada 2005

164.e/3 {*AI05-0001-1*} Generalized the definition of Move. Specified which elements are read/written by stream attributes.

164.f/3 {*AI05-0022-1*} **Correction:** Added a Bounded (Run-Time) Error to cover tampering by generic actual subprograms.

164.g/3 {*AI05-0027-1*} **Correction:** Added a Bounded (Run-Time) Error to cover access to finalized list containers.

164.h/3 {*AI05-0044-1*} **Correction:** Redefined "<" actuals to require a strict weak ordering; the old definition allowed indeterminant comparisons that would not have worked in a container.

164.i/3 {*AI05-0084-1*} **Correction:** Added a pragma Remote_Types so that containers can be used in distributed programs.

164.j/3 {*AI05-0160-1*} **Correction:** Revised the definition of invalid cursors to cover missing (and new) cases.

164.k/3 {*AI05-0257-1*} **Correction:** Added missing wording to describe the Position after Inserting 0 elements.

164.l/3 {*AI05-0265-1*} **Correction:** Defined when a container prohibits tampering in order to more clearly define where the check is made and the exception raised.

Inconsistencies With Ada 2012

164.m/5 {*AI12-0111-1*} **Correction:** Tampering with elements is now defined to be equivalent to tampering with cursors for ordinary containers. If a program requires tampering detection to work, it might fail in Ada 2022. Needless to say, this shouldn't happen outside of test programs. See Inconsistencies With Ada 2012 in A.18.2 for more details.

Incompatibilities With Ada 2012

164.n/5 {*AI12-0111-1*} {*AI12-0112-1*} {*AI12-0339-1*} {*AI12-0391-1*} A number of new subprograms, types, and even a nested package were added to Containers.Doubly_Linked_Lists to better support contracts and stable views. Therefore, a use clause conflict is possible; see the introduction of Annex A for more on this topic.

Extensions to Ada 2012

164.o/5 {*AI12-0196-1*} Replace_Element is now defined such that it can be used concurrently so long as it operates on different elements. This allows some container operations to be used in parallel without separate synchronization.

164.p/5 {*AI12-0212-1*} {*AI12-0391-1*} Lists now support positional container aggregates, so aggregate syntax can be used to create Lists.

164.q/5 {*AI12-0266-1*} The iterator for the entire container now can return a parallel iterator which can be used to process the container in parallel.

Wording Changes from Ada 2012

164.r/4 {*AI12-0110-1*} **Corrigendum:** Clarified that tampering checks precede all other checks made by a subprogram (but come after those associated with the call).

164.s/5 {*AI12-0112-1*} Added contracts to this container. This includes describing some of the semantics with pre- and postconditions, rather than English text. Note that the preconditions can be Suppressed (see 11.5).

{*AI12-0400-1*} **Correction:** Split the Append routine into two routines rather than having a single routine with a default parameter, in order that a routine with the appropriate profile for the Aggregate aspect exists. This change should not change the behavior of any existing code. 164.t/5

A.18.4 Maps

{*AI95-00302-03*} The language-defined generic packages Containers.Hashed_Maps and Containers.Ordered_Maps provide private types Map and Cursor, and a set of operations for each type. A map container allows an arbitrary type to be used as a key to find the element associated with that key. A hashed map uses a hash function to organize the keys, while an ordered map orders the keys per a specified relation. 1/2

{*AI95-00302-03*} {*AI05-0299-1*} This subclause describes the declarations that are common to both kinds of maps. See A.18.5 for a description of the semantics specific to Containers.Hashed_Maps and A.18.6 for a description of the semantics specific to Containers.Ordered_Maps. 2/3

Static Semantics

{*AI95-00302-03*} The actual function for the generic formal function "=" on Element_Type values is expected to define a reflexive and symmetric relationship and return the same result value each time it is called with a particular pair of values. If it behaves in some other manner, the function "=" on map values returns an unspecified value. The exact arguments and number of calls of this generic formal function by the function "=" on map values are unspecified. 3/2

Ramification: If the actual function for "=" is not symmetric and consistent, the result returned by "=" for Map objects cannot be predicted. The implementation is not required to protect against "=" raising an exception, or returning random results, or any other “bad” behavior. And it can call "=" in whatever manner makes sense. But note that only the result of "=" for Map objects is unspecified; other subprograms are not allowed to break if "=" is bad (they aren't expected to use "="). 3.a/2

{*AI95-00302-03*} The type Map is used to represent maps. The type Map needs finalization (see 7.6). 4/2

{*AI95-00302-03*} A map contains pairs of keys and elements, called *nodes*. Map cursors designate nodes, but also can be thought of as designating an element (the element contained in the node) for consistency with the other containers. There exists an equivalence relation on keys, whose definition is different for hashed maps and ordered maps. A map never contains two or more nodes with equivalent keys. The *length* of a map is the number of nodes it contains. 5/2

{*AI95-00302-03*} Each nonempty map has two particular nodes called the *first node* and the *last node* (which may be the same). Each node except for the last node has a *successor node*. If there are no other intervening operations, starting with the first node and repeatedly going to the successor node will visit each node in the map exactly once until the last node is reached. The exact definition of these terms is different for hashed maps and ordered maps. 6/2

{*AI95-00302-03*} {*AI12-0111-1*} {*AI12-0112-1*} [Some operations check for “tampering with cursors” of a container because they depend on the set of elements of the container remaining constant, and others check for “tampering with elements” of a container because they depend on elements of the container not being replaced.] When tampering with cursors is *prohibited* for a particular map object *M*, Program_Error is propagated by the finalization of *M*[, as well as by a call that passes *M* to certain of the operations of this package, as indicated by the precondition of such an operation]. Similarly, when tampering with elements is *prohibited* for *M*, Program_Error is propagated by a call that passes *M* to certain of the other operations of this package, as indicated by the precondition of such an operation. 7/5

Paragraphs 8 through 15 are removed as preconditions now describe these rules.

Ramification: We don't need to explicitly mention assignment_statement, because that finalizes the target object as part of the operation, and finalization of an object is already defined as tampering with cursors. 10.a/3

16/2 {*AI95-00302-03*} Empty_Map represents the empty Map object. It has a length of 0. If an object of type Map is not otherwise initialized, it is initialized to the same value as Empty_Map.

17/2 {*AI95-00302-03*} No_Element represents a cursor that designates no node. If an object of type Cursor is not otherwise initialized, it is initialized to the same value as No_Element.

18/5 {*AI95-00302-03*} {*AI12-0434-1*} The primitive "=" operator for type Cursor returns True if both cursors are No_Element, or designate the same element in the same container.

18.a/5 **To be honest:** {*AI12-0434-1*} "The primitive "=" operator" is the one with two parameters of type Cursor which returns Boolean. We're not talking about some other (hidden) primitive function named "=".

19/2 {*AI95-00302-03*} Execution of the default implementation of the Input, Output, Read, or Write attribute of type Cursor raises Program_Error.

19.a/2 **Reason:** A cursor will probably be implemented in terms of one or more access values, and the effects of streaming access values is unspecified. Rather than letting the user stream junk by accident, we mandate that streaming of cursors raise Program_Error by default. The attributes can always be specified if there is a need to support streaming.

19.1/5 {*AI05-0001-1*} {*AI05-0262-1*} {*AI12-0437-1*} Map'Write for a Map object *M* writes Length(*M*) elements of the map to the stream. It may also write additional information about the map.

19.2/3 {*AI05-0001-1*} {*AI05-0262-1*} Map'Read reads the representation of a map from the stream, and assigns to *Item* a map with the same length and elements as was written by Map'Write.

19.b/3 **Ramification:** Streaming more elements than the container length is wrong. For implementation implications of this rule, see the Implementation Note in A.18.2.

19.3/5
```
{AI12-0112-1} function Has_Element (Position : Cursor) return Boolean
   with Nonblocking, Global => in all, Use_Formal => null;
```

19.4/3 {*AI05-0212-1*} Returns True if Position designates an element, and returns False otherwise.

19.c/3 **To be honest:** {*AI05-0005-1*} {*AI05-0212-1*} This function might not detect cursors that designate deleted elements; such cursors are invalid (see below) and the result of calling Has_Element with an invalid cursor is unspecified (but not erroneous).

19.5/5
```
{AI12-0112-1} function Has_Element (Container : Map; Position : Cursor)
   return Boolean
   with Nonblocking, Global => null, Use_Formal => null;
```

19.6/5 {*AI12-0112-1*} Returns True if Position designates an element in Container, and returns False otherwise.

19.d/5 **Ramification:** {*AI12-0112-1*} If Position is No_element, Has_Element returns False.

20/2
```
function "=" (Left, Right : Map) return Boolean;
```

21/2 {*AI95-00302-03*} If Left and Right denote the same map object, then the function returns True. If Left and Right have different lengths, then the function returns False. Otherwise, for each key *K* in Left, the function returns False if:

22/2 - a key equivalent to *K* is not present in Right; or

23/2 - the element associated with *K* in Left is not equal to the element associated with *K* in Right (using the generic formal equality operator for elements).

24/2 If the function has not returned a result after checking all of the keys, it returns True. Any exception raised during evaluation of key equivalence or element equality is propagated.

24.a/2 **Implementation Note:** This wording describes the canonical semantics. However, the order and number of calls on the formal equality function is unspecified for all of the operations that use it in this package, so an implementation can call it as many or as few times as it needs to get the correct answer. Specifically, there is no requirement to call the formal equality additional times once the answer has been determined.

```
function Tampering_With_Cursors_Prohibited                                    24.1/5
   (Container : Map) return Boolean
   with Nonblocking, Global => null, Use_Formal => null;
```

{*AI12-0112-1*} Returns True if tampering with cursors or tampering with elements is currently prohibited for Container, and returns False otherwise. 24.2/5

Reason: {*AI12-0112-1*} Prohibiting tampering with elements also needs to prohibit tampering with cursors, as deleting an element is similar to replacing it. 24.b/5

Implementation Note: {*AI12-0112-1*} Various contracts elsewhere in this specification require that this function be implemented with synchronized data. Moreover, it is possible for tampering to be prohibited by multiple operations (sequentially or in parallel). Therefore, tampering needs to be implemented with an atomic or protected counter. The counter is initialized to zero, and is incremented when tampering is prohibited, and decremented when leaving an area that prohibited tampering. Function Tampering_With_Cursors_Prohibited returns True if the counter is nonzero. (Note that any case where the result is not well-defined for one task is incorrect use of shared variables and would be erroneous by the rules of 9.10, so no special protection is needed to read the counter.) 24.c/5

```
function Tampering_With_Elements_Prohibited                                   24.3/5
   (Container : Map) return Boolean
   with Nonblocking, Global => null, Use_Formal => null;
```

{*AI12-0112-1*} Always returns False[, regardless of whether tampering with elements is prohibited]. 24.4/5

Reason: {*AI12-0111-1*} A definite element cannot change size, so we allow operations that tamper with elements even when tampering with elements is prohibited. That's not true for the indefinite containers, which is why this kind of tampering exists. 24.d/5

```
{AI12-0112-1} function Length (Container : Map) return Count_Type             25/5
   with Nonblocking, Global => null, Use_Formal => null;
```

{*AI95-00302-03*} Returns the number of nodes in Container. 26/2

```
function Is_Empty (Container : Map) return Boolean                            27/5
   with Nonblocking, Global => null, Use_Formal => null,
        Post => Is_Empty'Result = (Length (Container) = 0);
```

{*AI95-00302-03*} {*AI12-0112-1*} Returns True if Container is empty. 28/5

```
{AI12-0112-1} procedure Clear (Container : in out Map)                        29/5
   with Pre  => not Tampering_With_Cursors_Prohibited (Container)
                    or else raise Program_Error,
        Post => Length (Container) = 0;
```

{*AI95-00302-03*} Removes all the nodes from Container. 30/2

```
function Key (Position : Cursor) return Key_Type                              31/5
   with Pre  => Position /= No_Element
                    or else raise Constraint_Error,
        Nonblocking, Global => in all, Use_Formal => Key_Type;
```

{*AI95-00302-03*} {*AI12-0112-1*} Key returns the key component of the node designated by Position. 32/5

```
function Key (Container : Map;                                                32.1/5

                   or else raise Program_Error),
        Nonblocking, Global => null, Use_Formal => Key_Type;
```

{*AI12-0112-1*} Key returns the key component of the node designated by Position. 32.2/5

33/5
```
function Element (Position : Cursor) return Element_Type
   with Pre  => Position /= No_Element
                   or else raise Constraint_Error,
        Nonblocking, Global => in all, Use_Formal => Element_Type;
```

34/5 {*AI95-00302-03*} {*AI12-0112-1*} Element returns the element component of the node designated by Position.

34.1/5
```
function Element (Container : Map;
                  Position  : Cursor) return Element_Type
   with Pre  => (Position /= No_Element
                   or else raise Constraint_Error) and then
                (Has_Element (Container, Position)
                   or else raise Program_Error),
        Nonblocking, Global => null, Use_Formal => Element_Type;
```

34.2/5 {*AI12-0112-1*} Element returns the element component of the node designated by Position.

35/5
```
procedure Replace_Element (Container : in out Map;
                           Position  : in     Cursor;
                           New_item  : in     Element_Type)
   with Pre  => (not Tampering_With_Elements_Prohibited (Container)
                   or else raise Program_Error) and then
                (Position /= No_Element
                   or else raise Constraint_Error) and then
                (Has_Element (Container, Position)
                   or else raise Program_Error);
```

36/5 {*AI95-00302-03*} {*AI05-0264-1*} {*AI12-0112-1*} {*AI12-0196-1*} Replace_Element assigns New_Item to the element of the node designated by Position. For the purposes of determining whether the parameters overlap in a call to Replace_Element, the Container parameter is not considered to overlap with any object [(including itself)].

37/5
```
procedure Query_Element
  (Position : in Cursor;
   Process  : not null access procedure (Key     : in Key_Type;
                                         Element : in Element_Type))
   with Pre  => Position /= No_Element
                   or else raise Constraint_Error,
        Global => in all;
```

38/5 {*AI95-00302-03*} {*AI05-0021-1*} {*AI05-0265-1*} {*AI12-0112-1*} Query_Element calls Process.**all** with the key and element from the node designated by Position as the arguments. Tampering with the elements of the map that contains the element designated by Position is prohibited during the execution of the call on Process.**all**. Any exception raised by Process.**all** is propagated.

38.1/5
```
procedure Query_Element
  (Container : in Map;
   Position  : in Cursor;
   Process   : not null access procedure (Key     : in Key_Type;
                                          Element : in Element_Type))
  with Pre  => (Position /= No_Element
                   or else raise Constraint_Error) and then
               (Has_Element (Container, Position)
                   or else raise Program_Error);
```

38.2/5 {*AI12-0112-1*} Query_Element calls Process.**all** with the key and element from the node designated by Position as the arguments. Tampering with the elements of Container is prohibited during the execution of the call on Process.**all**. Any exception raised by Process.**all** is propagated.

```
procedure Update_Element                                                    39/5
  (Container : in out Map;
   Position  : in     Cursor;
   Process   : not null access procedure (Key     : in     Key_Type;
                                          Element : in out Element_Type))
   with Pre  => (Position /= No_Element
                    or else raise Constraint_Error) and then
                 (Has_Element (Container, Position)
                    or else raise Program_Error);
```

{*AI95-00302-03*} {*AI05-0264-1*} {*AI05-0265-1*} {*AI12-0112-1*} Update_Element calls Process.**all** with the key and element from the node designated by Position as the arguments. Tampering with the elements of Container is prohibited during the execution of the call on Process.**all**. Any exception raised by Process.**all** is propagated. 40/5

If Element_Type is unconstrained and definite, then the actual Element parameter of Process.**all** shall be unconstrained. 41/2

Ramification: This means that the elements cannot be directly allocated from the heap; it must be possible to change the discriminants of the element in place. 41.a/2

```
{AI12-0112-1} type Constant_Reference_Type                                  41.1/5
      (Element : not null access constant Element_Type) is private
   with Implicit_Dereference => Element,
        Nonblocking, Global =>in out synchronized,
        Default_Initial_Condition => (raise Program_Error);
```

```
{AI12-0112-1} type Reference_Type (Element : not null access Element_Type) is  41.2/5
private
   with Implicit_Dereference => Element,
        Nonblocking, Global => in out synchronized,
        Default_Initial_Condition => (raise Program_Error);
```

{*AI05-0212-1*} The types Constant_Reference_Type and Reference_Type need finalization. 41.3/3

This paragraph was deleted.{*AI12-0112-1*} 41.4/5

Reason: It is expected that Reference_Type (and Constant_Reference_Type) will be a controlled type, for which finalization will have some action to terminate the tampering check for the associated container. If the object is created by default, however, there is no associated container. Since this is useless, and supporting this case would take extra work, we define it to raise an exception. 41.b/3

```
{AI12-0112-1} function Constant_Reference (Container : aliased in Map;      41.5/5
                           Position  : in Cursor)
   return Constant_Reference_Type
   with Pre  => (Position /= No_Element
                    or else raise Constraint_Error) and then
                 (Has_Element (Container, Position)
                    or else raise Program_Error),
        Post => Tampering_With_Cursors_Prohibited (Container),
        Nonblocking, Global => null, Use_Formal => null;
```

{*AI05-0212-1*} {*AI05-0269-1*} This function (combined with the Constant_Indexing and Implicit_Dereference aspects) provides a convenient way to gain read access to an individual element of a Map given a cursor. 41.6/3

{*AI05-0212-1*} {*AI05-0265-1*} {*AI12-0112-1*} Constant_Reference returns an object whose discriminant is an access value that designates the element designated by Position. Tampering with the elements of Container is prohibited while the object returned by Constant_Reference exists and has not been finalized. 41.7/5

41.8/5
```
{AI12-0112-1} function Reference (Container : aliased in out Map;
                                  Position  : in Cursor)
   return Reference_Type

        Nonblocking, Global => null, Use_Formal => null;
```

41.15/3 {*AI05-0212-1*} {*AI05-0269-1*} This function (combined with the Variable_Indexing and Implicit_Dereference aspects) provides a convenient way to gain read and write access to an individual element of a map given a key value.

41.16/3 Equivalent to Reference (Container, Find (Container, Key)).

41.17/5
```
{AI12-0112-1} procedure Assign (Target : in out Map; Source : in Map)
   with Pre  => not Tampering_With_Cursors_Prohibited (Target)
                    or else raise Program_Error,
        Post => Length (Source) = Length (Target);
```

41.18/3 {*AI05-0001-1*} {*AI05-0248-1*} If Target denotes the same object as Source, the operation has no effect. Otherwise, the key/element pairs of Source are copied to Target as for an assignment_statement assigning Source to Target.

41.c/3 **Discussion:** {*AI05-0005-1*} This routine exists for compatibility with the bounded map containers. For an unbounded map, `Assign(A, B)` and `A := B` behave identically. For a bounded map, := will raise an exception if the container capacities are different, while Assign will not raise an exception if there is enough room in the target.

```
{AI12-0112-1} procedure Move (Target : in out Map;                                    42/5
                              Source : in out Map)
   with Pre  => (not Tampering_With_Cursors_Prohibited (Target)
                     or else raise Program_Error) and then
                 (not Tampering_With_Cursors_Prohibited (Source)
                     or else raise Program_Error),
        Post => (if not Target'Has_Same_Storage (Source) then
                     Length (Target) = Length (Source'Old) and then
                     Length (Source) = 0);
```

{*AI95-00302-03*} {*AI05-0001-1*} {*AI05-0248-1*} {*AI05-0262-1*} If Target denotes the same object as Source, then the operation has no effect. Otherwise, the operation is equivalent to Assign (Target, Source) followed by Clear (Source). 43/3

```
{AI12-0112-1} procedure Insert (Container : in out Map;                               44/5
                                Key       : in     Key_Type;
                                New_Item  : in     Element_Type;
                                Position  :    out Cursor;
                                Inserted  :    out Boolean)
   with Pre  => (not Tampering_With_Cursors_Prohibited (Container)
                     or else raise Program_Error) and then
                 (Length (Container) <= Count_Type'Last - 1
                     or else raise Constraint_Error),
        Post => (declare
                    Original_Length : constant Count_Type :=
                       Length (Container)'Old;
                 begin
                   Has_Element (Container, Position) and then
                   (if Inserted then
                      Length (Container) = Original_Length + 1
                    else
                      Length (Container) = Original_Length));
```

{*AI95-00302-03*} Insert checks if a node with a key equivalent to Key is already present in Container. If a match is found, Inserted is set to False and Position designates the element with the matching key. Otherwise, Insert allocates a new node, initializes it to Key and New_Item, and adds it to Container; Inserted is set to True and Position designates the newly-inserted node. Any exception raised during allocation is propagated and Container is not modified. 45/2

```
{AI12-0112-1} procedure Insert (Container : in out Map;                               46/5
                                Key       : in     Key_Type;
                                Position  :    out Cursor;
                                Inserted  :    out Boolean)
   with Pre  => (not Tampering_With_Cursors_Prohibited (Container)
                     or else raise Program_Error) and then
                 (Length (Container) <= Count_Type'Last - 1
                     or else raise Constraint_Error),
        Post => (declare
                    Original_Length : constant Count_Type :=
                       Length (Container)'Old;
                 begin
                   Has_Element (Container, Position) and then
                   (if Inserted then
                      Length (Container) = Original_Length + 1
                    else
                      Length (Container) = Original_Length));
```

{*AI95-00302-03*} Insert inserts Key into Container as per the five-parameter Insert, with the difference that an element initialized by default (see 3.3.1) is inserted. 47/2

48/5
```
{AI12-0112-1} procedure Insert (Container : in out Map;
                    Key       : in     Key_Type;
                    New_Item  : in     Element_Type)
   with Pre  => (not Tampering_With_Cursors_Prohibited (Container)
                     or else raise Program_Error) and then
                (Length (Container) <= Count_Type'Last - 1
                     or else raise Constraint_Error),
        Post => Length (Container) = Length (Container)'Old + 1;
```

49/2 {*AI95-00302-03*} Insert inserts Key and New_Item into Container as per the five-parameter Insert, with the difference that if a node with a key equivalent to Key is already in the map, then Constraint_Error is propagated.

49.a/2 **Ramification:** This is equivalent to:

49.b/2
```
declare
  Inserted : Boolean; C : Cursor;
begin
  Insert (Container, Key, New_Item, C, Inserted);
  if not Inserted then
     raise Constraint_Error;
  end if;
end;
```

49.c/2 but doesn't require the hassle of **out** parameters.

50/5
```
{AI12-0112-1} procedure Include (Container : in out Map;
                    Key       : in     Key_Type;
                    New_Item  : in     Element_Type)
   with Pre  => (not Tampering_With_Cursors_Prohibited (Container)
                     or else raise Program_Error) and then
                (Length (Container) <= Count_Type'Last - 1
                     or else raise Constraint_Error),
        Post => (declare
                   Original_Length : constant Count_Type :=
                      Length (Container)'Old;
                 begin
                   Length (Container)
                      in Original_Length | Original_Length + 1);
```

51/2 {*AI95-00302-03*} Include inserts Key and New_Item into Container as per the five-parameter Insert, with the difference that if a node with a key equivalent to Key is already in the map, then this operation assigns Key and New_Item to the matching node. Any exception raised during assignment is propagated.

51.a/2 **Ramification:** This is equivalent to:

51.b/2
```
declare
  C : Cursor := Find (Container, Key);
begin
  if C = No_Element then
     Insert (Container, Key, New_Item);
  else
     Replace (Container, Key, New_Item);
  end if;
end;
```

51.c/2 but this avoids doing the search twice.

52/5
```
{AI12-0112-1} procedure Replace (Container : in out Map;
                    Key       : in     Key_Type;
                    New_Item  : in     Element_Type)
   with Pre  => not Tampering_With_Cursors_Prohibited (Container)
                     or else raise Program_Error,
        Post => Length (Container) = Length (Container)'Old;
```

53/2 {*AI95-00302-03*} Replace checks if a node with a key equivalent to Key is present in Container. If a match is found, Replace assigns Key and New_Item to the matching node; otherwise, Constraint_Error is propagated.

Discussion: We update the key as well as the element, as the key might include additional information that does not participate in equivalence. If only the element needs to be updated, use Replace_Element (Find (Container, Key), New_Element). 53.a/2

```
{AI12-0112-1} procedure Exclude (Container : in out Map;                    54/5
                  Key       : in     Key_Type)
   with Pre  => not Tampering_With_Cursors_Prohibited (Container)
                    or else raise Program_Error,
        Post => (declare
                    Original_Length : constant Count_Type :=
                       Length (Container)'Old;
                 begin
                    Length (Container)
                       in Original_Length - 1 | Original_Length);
```

{*AI95-00302-03*} Exclude checks if a node with a key equivalent to Key is present in Container. If a match is found, Exclude removes the node from the map. 55/2

Ramification: Exclude should work on an empty map; nothing happens in that case. 55.a/2

```
{AI12-0112-1} procedure Delete (Container : in out Map;                     56/5
                  Key       : in     Key_Type)
   with Pre  => not Tampering_With_Cursors_Prohibited (Container)
                    or else raise Program_Error,
        Post => Length (Container) = Length (Container)'Old - 1;
```

{*AI95-00302-03*} Delete checks if a node with a key equivalent to Key is present in Container. If a match is found, Delete removes the node from the map; otherwise, Constraint_Error is propagated. 57/2

```
procedure Delete (Container : in out Map;                                   58/5
                  Position  : in out Cursor)
   with Pre  => (not Tampering_With_Cursors_Prohibited (Container)
                    or else raise Program_Error) and then
                (Position /= No_Element
                    or else raise Constraint_Error) and then
                (Has_Element (Container, Position)
                   or else raise Program_Error),
        Post => Length (Container) = Length (Container)'Old - 1 and then
                Position = No_Element;
```

{*AI95-00302-03*} {*AI12-0112-1*} Delete removes the node designated by Position from the map. 59/5

Ramification: The check on Position checks that the cursor does not belong to some other map. This check implies that a reference to the map is included in the cursor value. This wording is not meant to require detection of dangling cursors; such cursors are defined to be invalid, which means that execution is erroneous, and any result is allowed (including not raising an exception). 59.a/2

```
{AI12-0112-1} function First (Container : Map) return Cursor                60/5
   with Nonblocking, Global => null, Use_Formal => null,
        Post => (if not Is_Empty (Container)
                 then Has_Element (Container, First'Result)
                 else First'Result = No_Element);
```

{*AI95-00302-03*} If Length (Container) = 0, then First returns No_Element. Otherwise, First returns a cursor that designates the first node in Container. 61/2

```
{AI12-0112-1} function Next (Position : Cursor) return Cursor               62/5
   with Nonblocking, Global => in all, Use_Formal => null,
        Post => (if Position = No_Element then Next'Result = No_Element);
```

{*AI95-00302-03*} Returns a cursor that designates the successor of the node designated by Position. If Position designates the last node, then No_Element is returned. If Position equals No_Element, then No_Element is returned. 63/2

63.1/5
```
function Next (Container : Map;
               Position  : Cursor) return Cursor
   with Nonblocking, Global => null, Use_Formal => null,
        Pre  => Position = No_Element or else
                Has_Element (Container, Position)
                   or else raise Program_Error,
        Post => (if Position = No_Element then Next'Result = No_Element
                 elsif Next'Result = No_Element then
                   Position = Last (Container)
                 else Has_Element (Container, Next'Result));
```

63.2/5 {*AI12-0112-1*} Returns a cursor designating the successor of the node designated by Position in Container.

64/5
```
{AI12-0112-1} procedure Next (Position : in out Cursor)
   with Nonblocking, Global => in all, Use_Formal => null;
```

65/2 {*AI95-00302-03*} Equivalent to Position := Next (Position).

65.1/5
```
procedure Next (Container : in     Map;
                Position  : in out Cursor)
   with Nonblocking, Global => null, Use_Formal => null,
        Pre  => Position = No_Element or else
                Has_Element (Container, Position)
                   or else raise Program_Error,
        Post => (if Position /= No_Element
                 then Has_Element (Container, Position));
```

65.2/5 {*AI12-0112-1*} Equivalent to Position := Next (Container, Position).

66/5
```
{AI12-0112-1} function Find (Container : Map;
                             Key       : Key_Type) return Cursor
      with Post => (if Find'Result = No_Element
                    then Has_Element (Container, Find'Result));
```

67/2 {*AI95-00302-03*} If Length (Container) equals 0, then Find returns No_Element. Otherwise, Find checks if a node with a key equivalent to Key is present in Container. If a match is found, a cursor designating the matching node is returned; otherwise, No_Element is returned.

68/2
```
function Element (Container : Map;
                  Key       : Key_Type) return Element_Type;
```

69/2 {*AI95-00302-03*} Equivalent to Element (Find (Container, Key)).

70/2
```
function Contains (Container : Map;
                   Key       : Key_Type) return Boolean;
```

71/2 {*AI95-00302-03*} Equivalent to Find (Container, Key) /= No_Element.

Paragraphs 72 and 73 were moved above.

74/5
```
{AI12-0112-1} procedure Iterate
  (Container : in Map;
   Process   : not null access procedure (Position : in Cursor))
   with Allows_Exit;
```

75/3 {*AI95-00302-03*} {*AI05-0265-1*} Iterate calls Process.**all** with a cursor that designates each node in Container, starting with the first node and moving the cursor according to the successor relation. Tampering with the cursors of Container is prohibited during the execution of a call on Process.**all**. Any exception raised by Process.**all** is propagated.

75.a/2 **Implementation Note:** The “tamper with cursors” check takes place when the operations that insert or delete elements, and so on, are called.

75.b/2 See Iterate for vectors (A.18.2) for a suggested implementation of the check.

{*AI12-0111-1*} The nested package Stable provides a type Stable.Map that represents a *stable* map, which is one that cannot grow and shrink. Such a map can be created by calling the Copy function, or by establishing a *stabilized view* of an ordinary map. 75.1/5

{*AI12-0111-1*} The subprograms of the map package that have a parameter or result of type Map are included in the nested package Stable with the same specification, except that the following are omitted: 75.2/5

Tampering_With_Cursors_Prohibited, Tampering_With_Elements_Prohibited, Assign, Move, Insert, Include, Clear, Delete, Exclude, (for Ordered_Maps) Delete_First and Delete_Last, and (for Hashed_Maps) Reserve_Capacity 75.3/5

Ramification: The names Map and Cursor mean the types declared in the nested package in these subprogram specifications. 75.b.1/5

Reason: The omitted routines are those that tamper with cursors or elements (or test that state). The model is that it is impossible to tamper with cursors or elements of a stable view since no such operations are included. Thus tampering checks are not needed for a stable view, and we omit the operations associated with those checks. 75.b.2/5

{*AI12-0111-1*} The operations of this package are equivalent to those for ordinary maps, except that the calls to Tampering_With_Cursors_Prohibited and Tampering_With_Elements_Prohibited that occur in preconditions are replaced by False, and any that occur in postconditions are replaced by True. 75.4/5

{*AI12-0111-1*} {*AI12-0439-1*} If a stable map is declared with the Base discriminant designating a pre-existing ordinary map, the stable map represents a stabilized view of the underlying ordinary map, and any operation on the stable map is reflected on the underlying ordinary map. While a stabilized view exists, any operation that tampers with elements performed on the underlying map is prohibited. The finalization of a stable map that provides such a view removes this restriction on the underlying ordinary map [(though some other restriction can exist due to other concurrent iterations or stabilized views)]. 75.5/5

{*AI12-0111-1*} {*AI12-0438-1*} If a stable map is declared without specifying Base, the object is necessarily initialized. The initializing expression of the stable map, [typically a call on Copy], determines the Length of the map. The Length of a stable map never changes after initialization. 75.6/5

Proof: {*AI12-0438-1*} Initialization is required as the type is indefinite, see 3.3.1. 75.c/5

Bounded (Run-Time) Errors

{*AI05-0022-1*} {*AI05-0248-1*} It is a bounded error for the actual function associated with a generic formal subprogram, when called as part of an operation of a map package, to tamper with elements of any map parameter of the operation. Either Program_Error is raised, or the operation works as defined on the value of the map either prior to, or subsequent to, some or all of the modifications to the map. 75.7/3

{*AI05-0027-1*} It is a bounded error to call any subprogram declared in the visible part of a map package when the associated container has been finalized. If the operation takes Container as an **in out** parameter, then it raises Constraint_Error or Program_Error. Otherwise, the operation either proceeds as it would for an empty container, or it raises Constraint_Error or Program_Error. 75.8/3

Erroneous Execution

{*AI95-00302-03*} A Cursor value is *invalid* if any of the following have occurred since it was created: 76/2

- The map that contains the node it designates has been finalized; 77/2
- {*AI05-0160-1*} The map that contains the node it designates has been used as the Target of a call to Assign, or as the target of an assignment_statement; 77.1/3
- The map that contains the node it designates has been used as the Source or Target of a call to Move; or 78/2
- {*AI05-0160-1*} {*AI05-0262-1*} The node it designates has been removed from the map that previously contained the node. 79/3

79.a/3 **Ramification:** {*AI05-0160-1*} This can happen directly via calls to Clear, Exclude, and Delete.

80/2 The result of "=" or Has_Element is unspecified if these functions are called with an invalid cursor parameter. Execution is erroneous if any other subprogram declared in Containers.Hashed_Maps or Containers.Ordered_Maps is called with an invalid cursor parameter.

80.a/2 **Discussion:** The list above is intended to be exhaustive. In other cases, a cursor value continues to designate its original element. For instance, cursor values survive the insertion and deletion of other nodes.

80.b/2 While it is possible to check for these cases, in many cases the overhead necessary to make the check is substantial in time or space. Implementations are encouraged to check for as many of these cases as possible and raise Program_Error if detected.

80.1/3 {*AI05-0212-1*} Execution is erroneous if the map associated with the result of a call to Reference or Constant_Reference is finalized before the result object returned by the call to Reference or Constant_Reference is finalized.

80.c/3 **Reason:** Each object of Reference_Type and Constant_Reference_Type probably contains some reference to the originating container. If that container is prematurely finalized (which is only possible via Unchecked_Deallocation, as accessibility checks prevent passing a container to Reference that will not live as long as the result), the finalization of the object of Reference_Type will try to access a nonexistent object. This is a normal case of a dangling pointer created by Unchecked_Deallocation; we have to explicitly mention it here as the pointer in question is not visible in the specification of the type. (This is the same reason we have to say this for invalid cursors.)

Implementation Requirements

81/5 {*AI95-00302-03*} {*AI12-0437-1*} No storage associated with a map object shall be lost upon assignment or scope exit.

82/3 {*AI95-00302-03*} {*AI05-0262-1*} The execution of an assignment_statement for a map shall have the effect of copying the elements from the source map object to the target map object and changing the length of the target object to that of the source object.

82.a/3 **Implementation Note:** {*AI05-0298-1*} An assignment of a Map is a “deep” copy; that is the elements are copied as well as the data structures. We say “effect of” in order to allow the implementation to avoid copying elements immediately if it wishes. For instance, an implementation that avoided copying until one of the containers is modified would be allowed. (Note that this implementation would require care, see A.18.2 for more.)

Implementation Advice

83/2 {*AI95-00302-03*} Move should not copy elements, and should minimize copying of internal data structures.

83.a/2 **Implementation Advice:** Move for a map should not copy elements, and should minimize copying of internal data structures.

83.b/2 **Implementation Note:** Usually that can be accomplished simply by moving the pointer(s) to the internal data structures from the Source container to the Target container.

84/2 {*AI95-00302-03*} If an exception is propagated from a map operation, no storage should be lost, nor any elements removed from a map unless specified by the operation.

84.a/2 **Implementation Advice:** If an exception is propagated from a map operation, no storage should be lost, nor any elements removed from a map unless specified by the operation.

84.b/2 **Reason:** This is important so that programs can recover from errors. But we don't want to require heroic efforts, so we just require documentation of cases where this can't be accomplished.

Wording Changes from Ada 95

84.c/2 {*AI95-00302-03*} This description of maps is new; the extensions are documented with the specific packages.

Extensions to Ada 2005

84.d/3 {*AI05-0212-1*} Added reference support to make map containers more convenient to use.

Wording Changes from Ada 2005

{*AI05-0001-1*} Added procedure Assign; the extension and incompatibility is documented with the specific packages. 84.e/3

{*AI05-0001-1*} Generalized the definition of Move. Specified which elements are read/written by stream attributes. 84.f/3

{*AI05-0022-1*} **Correction:** Added a Bounded (Run-Time) Error to cover tampering by generic actual subprograms. 84.g/3

{*AI05-0027-1*} **Correction:** Added a Bounded (Run-Time) Error to cover access to finalized map containers. 84.h/3

{*AI05-0160-1*} **Correction:** Revised the definition of invalid cursors to cover missing (and new) cases. 84.i/3

{*AI05-0265-1*} **Correction:** Defined when a container prohibits tampering in order to more clearly define where the check is made and the exception raised. 84.j/3

Inconsistencies With Ada 2012

{*AI12-0111-1*} **Correction:** Tampering with elements is now defined to be equivalent to tampering with cursors for ordinary containers. If a program requires tampering detection to work, it might fail in Ada 2022. Needless to say, this shouldn't happen outside of test programs. See Inconsistencies With Ada 2012 in A.18.2 for more details. 84.k/5

Extensions to Ada 2012

{*AI12-0196-1*} **Correction:** Replace_Element is now defined such that it can be used concurrently so long as it operates on different elements. This allows some container operations to be used in parallel without separate synchronization. 84.l/5

Wording Changes from Ada 2012

{*AI12-0110-1*} **Correction:** Clarified that tampering checks precede all other checks made by a subprogram (but come after those associated with the call). 84.m/4

{*AI12-0112-1*} Added contracts to this container. This includes describing some of the semantics with pre- and postconditions, rather than English text. Note that the preconditions can be Suppressed (see 11.5). 84.n/5

A.18.5 The Generic Package Containers.Hashed_Maps

Static Semantics

{*AI95-00302-03*} The generic library package Containers.Hashed_Maps has the following declaration: 1/2

```
{AI05-0084-1} {AI05-0212-1} {AI12-0112-1} with Ada.Iterator_Interfaces;                2/5
generic
   type Key_Type is private;
   type Element_Type is private;
   with function Hash (Key : Key_Type) return Hash_Type;
   with function Equivalent_Keys (Left, Right : Key_Type)
      return Boolean;
   with function "=" (Left, Right : Element_Type)
      return Boolean is <>;
package Ada.Containers.Hashed_Maps
   with Preelaborate, Remote_Types,
        Nonblocking, Global => in out synchronized is
```

Discussion: {*AI12-0112-1*} For discussion on the reasons and meaning of the specifications of the Global and Nonblocking aspects in this generic package, see the notes on the equivalent operations in the specification of the Containers.Vectors package (see A.18.2). 2.a/5

3/5
```
{AI05-0212-1} {AI12-0111-1} {AI12-0112-1} {AI12-0212-1} {AI12-0339-1} {AI12-0339-1}
type Map is tagged private
      with Constant_Indexing => Constant_Reference,
           Variable_Indexing => Reference,
           Default_Iterator  => Iterate,
           Iterator_Element  => Element_Type,
           Iterator_View     => Stable.Map,
           Aggregate         => (Empty     => Empty,
                                 Add_Named => Insert),
           Stable_Properties => (Length,
                                 Tampering_With_Cursors_Prohibited,
                                 Tampering_With_Elements_Prohibited),
           Default_Initial_Condition =>
              Length (Map) = 0 and then
              (not Tampering_With_Cursors_Prohibited (Map)) and then
              (not Tampering_With_Elements_Prohibited (Map)),
           Preelaborable_Initialization;
```

3.a/5 **Discussion:** {*AI12-0112-1*} Unlike a Vector, the Stable_Properties of a Hashed_Map do not include the Capacity. If we had included it, some of the otherwise shared definitions would need different postconditions for Hashed_Maps and Ordered_Maps. If we were starting these containers from scratch, we probably would have approached the sharing of definitions differently so that we could avoid issues like this, but a major reorganization of this existing material would be too much change.

4/5
```
{AI12-0399-1}    type Cursor is private
      with Preelaborable_Initialization;
```

5/2

40/2        end Ada.Containers.Hashed_Maps;
```

41/2 {*AI95-00302-03*} An object of type Map contains an expandable hash table, which is used to provide direct access to nodes. The *capacity* of an object of type Map is the maximum number of nodes that can be inserted into the hash table prior to it being automatically expanded.

41.a/2 **Implementation Note:** The expected implementation for a Map uses a hash table which is grown when it is too small, with linked lists hanging off of each bucket. Note that in that implementation a cursor needs a back pointer to the Map object to implement iteration; that could either be in the nodes, or in the cursor object. To provide an average *O*(1) access time, capacity would typically equal the number of buckets in such an implementation, so that the average bucket linked list length would be no more than 1.0.

41.b/2 There is no defined relationship between elements in a hashed map. Typically, iteration will return elements in the order that they are hashed in.

42/2 {*AI95-00302-03*} Two keys *K1* and *K2* are defined to be *equivalent* if Equivalent_Keys (*K1*, *K2*) returns True.

43/2 {*AI95-00302-03*} The actual function for the generic formal function Hash is expected to return the same value each time it is called with a particular key value. For any two equivalent key values, the actual for Hash is expected to return the same value. If the actual for Hash behaves in some other manner, the behavior of this package is unspecified. Which subprograms of this package call Hash, and how many times they call it, is unspecified.

43.a/2 **Implementation Note:** The implementation is not required to protect against Hash raising an exception, or returning random numbers, or any other “bad” behavior. It's not practical to do so, and a broken Hash function makes the container unusable.

43.b/2 The implementation can call Hash whenever it is needed; we don't want to specify how often that happens. The result must remain the same (this is logically a pure function), or the behavior is unspecified.

44/2 {*AI95-00302-03*} The actual function for the generic formal function Equivalent_Keys on Key_Type values is expected to return the same value each time it is called with a particular pair of key values. It should define an equivalence relationship, that is, be reflexive, symmetric, and transitive. If the actual for

Equivalent_Keys behaves in some other manner, the behavior of this package is unspecified. Which subprograms of this package call Equivalent_Keys, and how many times they call it, is unspecified.

Implementation Note: As with Hash, the implementation is not required to protect against Equivalent_Keys raising an exception or returning random results. Similarly, the implementation can call this operation whenever it is needed. The result must remain the same (this is a logically pure function), or the behavior is unspecified. 44.a/2

{*AI95-00302-03*} If the value of a key stored in a node of a map is changed other than by an operation in this package such that at least one of Hash or Equivalent_Keys give different results, the behavior of this package is unspecified. 45/2

Implementation Note: The implementation is not required to protect against changes to key values other than via the operations declared in the Hashed_Maps package. 45.a/2

To see how this could happen, imagine an instance of Hashed_Maps where the key type is an access-to-variable type and Hash returns a value derived from the components of the designated object. Then, any operation that has a key value could modify those components and change the hash value: 45.b/2

```
Key (Map).Some_Component := New_Value;
```
45.c/2

This is really a design error on the part of the user of the map; it shouldn't be possible to modify keys stored in a map. But we can't prevent this error anymore than we can prevent someone passing as Hash a random number generator. 45.d/2

{*AI95-00302-03*} Which nodes are the first node and the last node of a map, and which node is the successor of a given node, are unspecified, other than the general semantics described in A.18.4. 46/2

Implementation Note: Typically the first node will be the first node in the first bucket, the last node will be the last node in the last bucket, and the successor will be obtained by following the collision list, and going to the next bucket at the end of each bucket. 46.a/2

```
function Empty (Capacity : Count_Type := implementation-defined)
   return Map
   with Post =>
           Capacity (Empty'Result) >= Capacity and then
           not Tampering_With_Elements_Prohibited (Empty'Result) and then
           not Tampering_With_Cursors_Prohibited (Empty'Result) and then
           Length (Empty'Result) = 0;
```
46.1/5

{*AI12-0339-1*} Returns an empty map. 46.2/2

```
{AI12-0112-1} function Capacity (Container : Map) return Count_Type
   with Nonblocking, Global => null, Use_Formal => null;
```
47/5

{*AI95-00302-03*} Returns the capacity of Container. 48/2

```
{AI12-0112-1} procedure Reserve_Capacity (Container : in out Map;
                                          Capacity  : in     Count_Type)
   with Pre  => not Tampering_With_Cursors_Prohibited (Container)
                or else raise Program_Error,
        Post => Container.Capacity >= Capacity;
```
49/5

{*AI95-00302-03*} Reserve_Capacity allocates a new hash table such that the length of the resulting map can become at least the value Capacity without requiring an additional call to Reserve_Capacity, and is large enough to hold the current length of Container. Reserve_Capacity then rehashes the nodes in Container onto the new hash table. It replaces the old hash table with the new hash table, and then deallocates the old hash table. Any exception raised during allocation is propagated and Container is not modified. 50/2

This paragraph was deleted.{*AI12-0112-1*} 51/5

Implementation Note: This routine is used to preallocate the internal hash table to the specified capacity such that future Inserts do not require expansion of the hash table. Therefore, the implementation should allocate the needed memory to make that true at this point, even though the visible semantics could be preserved by waiting until enough elements are inserted. 51.a/2

{*AI05-0005-1*} While Reserve_Capacity can be used to reduce the capacity of a map, we do not specify whether an implementation actually supports reduction of the capacity. Since the actual capacity can be anything greater than or equal to Capacity, an implementation never has to reduce the capacity. 51.b/3

51.c/2 Reserve_Capacity tampers with the cursors, as rehashing probably will change the order that elements are stored in the map.

52/5
```
{AI12-0112-1} procedure Clear (Container : in out Map)
   with Pre  => not Tampering_With_Cursors_Prohibited (Container)
                    or else raise Program_Error,
        Post => Capacity (Container) = Capacity (Container)'Old and then
                Length (Container) = 0;
```

53/2 {*AI95-00302-03*} In addition to the semantics described in A.18.4, Clear does not affect the capacity of Container.

53.1/5
```
{AI12-0112-1} procedure Assign (Target : in out Map; Source : in Map)
      with Pre  => not Tampering_With_Cursors_Prohibited (Target)
                       or else raise Program_Error,
           Post => Length (Source) = Length (Target) and then
                   Capacity (Target) >= Length (Source);
```

53.2/3 {*AI05-0001-1*} {*AI05-0248-1*} In addition to the semantics described in A.18.4, if the length of Source is greater than the capacity of Target, Reserve_Capacity (Target, Length (Source)) is called before assigning any elements.

53.3/5
```
function Copy (Source : Map; Capacity : Count_Type := 0)
   return Map
   with Pre  => Capacity = 0 or else Capacity >= Length (Source)
                   or else raise Capacity_Error,
        Post =>
           Length (Copy'Result) = Length (Source) and then
           not Tampering_With_Elements_Prohibited (Copy'Result) and then
           not Tampering_With_Cursors_Prohibited (Copy'Result) and then
           Copy'Result.Capacity = (if Capacity = 0 then
              Length (Source) else Capacity);
```

53.4/5 {*AI05-0001-1*} {*AI12-0112-1*} Returns a map whose keys and elements are initialized from the keys and elements of Source.

53.a/2 **Implementation Note:** In:

53.b/2
```
procedure Move (Target : in out Map;
                Source : in out Map);
```

53.c/2 The intended implementation is that the internal hash table of Target is first deallocated; then the internal hash table is removed from Source and moved to Target.

54/5
```
{AI12-0112-1} procedure Insert (Container : in out Map;
                  Key       : in     Key_Type;
                  New_Item  : in     Element_Type;
                  Position  :    out Cursor;
                  Inserted  :    out Boolean)
   with Pre  => (not Tampering_With_Cursors_Prohibited (Container)
                     or else raise Program_Error) and then
                (Length (Container) <= Count_Type'Last - 1
                     or else raise Constraint_Error),
        Post => (declare
                   Original_Length : constant Count_Type :=
                      Length (Container)'Old;
                 begin
                   Has_Element (Container, Position) and then
                  (if Inserted then
                     Length (Container) = Original_Length + 1
                   else
                     Length (Container) = Original_Length)) and then
                 Capacity (Container) >= Length (Container);
```

55/2 {*AI95-00302-03*} In addition to the semantics described in A.18.4, if Length (Container) equals Capacity (Container), then Insert first calls Reserve_Capacity to increase the capacity of Container to some larger value.

Implementation Note: Insert should only compare keys that hash to the same bucket in the hash table. 55.a/2

We specify when Reserve_Capacity is called to bound the overhead of capacity expansion operations (which are potentially expensive). Moreover, expansion can be predicted by comparing Capacity(Map) to Length(Map). Since we don't specify by how much the hash table is expanded, this only can be used to predict the next expansion, not later ones. 55.b/2

Implementation Note: In: 55.c/2

```
procedure Exclude (Container : in out Map;
                   Key       : in     Key_Type);
```
55.d/2

Exclude should only compare keys that hash to the same bucket in the hash table. 55.e/2

Implementation Note: In: 55.f/2

```
procedure Delete (Container : in out Map;
                  Key       : in     Key_Type);
```
55.g/2

Delete should only compare keys that hash to the same bucket in the hash table. The node containing the element may be deallocated now, or it may be saved and reused later. 55.h/2

Implementation Note: In: 55.i/2

```
function First (Container : Map) return Cursor;
```
55.j/2

In a typical implementation, this will be the first node in the lowest numbered hash bucket that contains a node. 55.k/2

Implementation Note: In: 55.l/2

```
function Next (Position  : Cursor) return Cursor;
```
55.m/2

In a typical implementation, this will return the next node in a bucket; if Position is the last node in a bucket, this will return the first node in the next nonempty bucket. 55.n/2

A typical implementation will need to a keep a pointer at the map container in the cursor in order to implement this function. 55.o/2

Implementation Note: In: 55.p/2

```
function Find (Container : Map;
               Key       : Key_Type) return Cursor;
```
55.q/2

Find should only compare keys that hash to the same bucket in the hash table. 55.r/2

```
{AI12-0112-1} function Equivalent_Keys (Left, Right : Cursor)
   return Boolean
   with Pre    => (Left /= No_Element and then Right /= No_Element)
                    or else raise Constraint_Error,
        Global => in all;
```
56/5

{*AI95-00302-03*} Equivalent to Equivalent_Keys (Key (Left), Key (Right)). 57/2

```
{AI12-0112-1} function Equivalent_Keys (Left  : Cursor;
                                        Right : Key_Type) return Boolean
   with Pre    => Left /= No_Element or else raise Constraint_Error,
        Global => in all;
```
58/5

{*AI95-00302-03*} Equivalent to Equivalent_Keys (Key (Left), Right). 59/2

```
{AI12-0112-1} function Equivalent_Keys (Left  : Key_Type;
                                        Right : Cursor) return Boolean
   with Pre    => Right /= No_Element or else raise Constraint_Error,
        Global => in all;
```
60/5

{*AI95-00302-03*} Equivalent to Equivalent_Keys (Left, Key (Right)). 61/2

```
{AI12-0112-1} {AI12-0266-1} function Iterate (Container : in Map)
   return Map_Iterator_Interfaces.Parallel_Iterator'Class
   with Post => Tampering_With_Cursors_Prohibited (Container);
```
61.1/5

{*AI05-0212-1*} {*AI05-0265-1*} {*AI05-0269-1*} {*AI12-0266-1*} Iterate returns an iterator object (see 5.5.1) that will generate a value for a loop parameter (see 5.5.2) designating each node in Container, starting with the first node and moving the cursor according to the successor relation when used as a forward iterator, and processing all nodes concurrently when used as a parallel iterator. Tampering with the cursors of Container is prohibited while the iterator object exists (in 61.2/5

particular, in the sequence_of_statements of the loop_statement whose iterator_specification denotes this object). The iterator object needs finalization.

Implementation Advice

62/2 {*AI95-00302-03*} If *N* is the length of a map, the average time complexity of the subprograms Element, Insert, Include, Replace, Delete, Exclude, and Find that take a key parameter should be *O*(log *N*). The average time complexity of the subprograms that take a cursor parameter should be *O*(1). The average time complexity of Reserve_Capacity should be *O*(*N*).

62.a/2 **Implementation Advice:** The average time complexity of Element, Insert, Include, Replace, Delete, Exclude, and Find operations that take a key parameter for Containers.Hashed_Maps should be *O*(log *N*). The average time complexity of the subprograms of Containers.Hashed_Maps that take a cursor parameter should be *O*(1). The average time complexity of Containers.Hashed_Maps.Reserve_Capacity should be *O*(*N*).

62.b/2 **Reason:** We do not mean to overly constrain implementation strategies here. However, it is important for portability that the performance of large containers has roughly the same factors on different implementations. If a program is moved to an implementation for which Find is *O*(*N*), that program could be unusable when the maps are large. We allow *O*(log *N*) access because the proportionality constant and caching effects are likely to be larger than the log factor, and we don't want to discourage innovative implementations.

Extensions to Ada 95

62.c/2 {*AI95-00302-03*} The generic package Containers.Hashed_Maps is new.

Incompatibilities With Ada 2005

62.d/3 {*AI05-0001-1*} Subprograms Assign and Copy are added to Containers.Hashed_Maps. If an instance of Containers.Hashed_Maps is referenced in a use_clause, and an entity *E* with the same defining_identifier as a new entity in Containers.Hashed_Maps is defined in a package that is also referenced in a use_clause, the entity *E* may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur.

Extensions to Ada 2005

62.e/3 {*AI05-0212-1*} Added iterator and indexing support to make hashed map containers more convenient to use.

Wording Changes from Ada 2005

62.f/3 {*AI05-0084-1*} **Correction:** Added a pragma Remote_Types so that containers can be used in distributed programs.

Incompatibilities With Ada 2012

62.g/5 {*AI12-0111-1*} {*AI12-0112-1*} {*AI12-0339-1*} A number of new subprograms, types, and even a nested package were added to Containers.Hashed_Maps to better support contracts and stable views. Therefore, a use clause conflict is possible; see the introduction of Annex A for more on this topic.

Extensions to Ada 2012

62.h/5 {*AI12-0212-1*} Maps now support named container aggregates, so aggregate syntax can be used to create Maps.

62.i/5 {*AI12-0266-1*} The iterator for the container now can return a parallel iterator which can be used to process the container in parallel.

Wording Changes from Ada 2012

62.j/5 {*AI12-0112-1*} Added contracts to this container. This includes describing some of the semantics with pre- and postconditions, rather than English text. Note that the preconditions can be Suppressed (see 11.5).

A.18.6 The Generic Package Containers.Ordered_Maps

Static Semantics

{*AI95-00302-03*} The generic library package Containers.Ordered_Maps has the following declaration: 1/2

```
{AI05-0084-1} {AI05-0212-1} {AI12-0112-1} with Ada.Iterator_Interfaces;                    2/5
generic
   type Key_Type is private;
   type Element_Type is private;
   with function "<" (Left, Right : Key_Type) return Boolean is <>;
   with function "=" (Left, Right : Element_Type) return Boolean is <>;
package Ada.Containers.Ordered_Maps
   with Preelaborate, Remote_Types,
        Nonblocking, Global => in out synchronized is
```

Discussion: {*AI12-0112-1*} For discussion on the reasons and meaning of the specifications of the Global and Nonblocking aspects in this generic package, see the notes on the equivalent operations in the specification of the Containers.Vectors package (see A.18.2). 2.a/5

```
{AI12-0112-1}    function Equivalent_Keys (Left, Right : Key_Type) return Boolean          3/5
      is (not ((Left < Right) or (Right < Left)));

55/2 {*AI95-00302-03*} Two keys *K1* and *K2* are *equivalent* if both *K1 < K2* and *K2 < K1* return False, using the generic formal "<" operator for keys. Function Equivalent_Keys returns True if Left and Right are equivalent, and False otherwise.

{*AI95-00302-03*} {*AI05-0044-1*} The actual function for the generic formal function "<" on Key_Type values is expected to return the same value each time it is called with a particular pair of key values. It should define a strict weak ordering relationship (see A.18). If the actual for "<" behaves in some other manner, the behavior of this package is unspecified. Which subprograms of this package call "<" and how many times they call it, is unspecified. 56/3

Implementation Note: The implementation is not required to protect against "<" raising an exception, or returning random results, or any other “bad” behavior. It's not practical to do so, and a broken "<" function makes the container unusable. 56.a/2

The implementation can call "<" whenever it is needed; we don't want to specify how often that happens. The result must remain the same (this is a logically pure function), or the behavior is unspecified. 56.b/2

{*AI95-00302-03*} If the value of a key stored in a map is changed other than by an operation in this package such that at least one of "<" or "=" give different results, the behavior of this package is unspecified. 57/2

Implementation Note: The implementation is not required to protect against changes to key values other than via the operations declared in the Ordered_Maps package. 57.a/2

To see how this could happen, imagine an instance of Ordered_Maps package where the key type is an access-to-variable type and "<" returns a value derived from comparing the components of the designated objects. Then, any operation that has a key value (even if the key value is constant) could modify those components and change the result of "<": 57.b/2

```
Key (Map).Some_Component := New_Value;
```
57.c/2

This is really a design error on the part of the user of the map; it shouldn't be possible to modify keys stored in a map such that "<" changes. But we can't prevent this error anymore than we can prevent someone passing as "<" a routine that produces random answers. 57.d/2

{*AI95-00302-03*} {*AI05-0262-1*} The *first node* of a nonempty map is the one whose key is less than the key of all the other nodes in the map. The *last node* of a nonempty map is the one whose key is greater than the key of all the other elements in the map. The *successor* of a node is the node with the smallest key that is larger than the key of the given node. The *predecessor* of a node is the node with the largest key that is smaller than the key of the given node. All comparisons are done using the generic formal "<" operator for keys. 58/3

```
{AI12-0112-1} function Copy (Source : Map)
   return Map
   with Post =>
      Length (Copy'Result) = Length (Source) and then
      not Tampering_With_Elements_Prohibited (Copy'Result) and then

```

88/2 {*AI95-00302-03*} Equivalent to Right < Key (Left).

89/5
```
{AI12-0112-1} function "<" (Left : Key_Type; Right : Cursor) return Boolean
   with Pre    => Right /= No_Element or else raise Constraint_Error,
           Global => in all;
```

90/2 {*AI95-00302-03*} Equivalent to Left < Key (Right).

91/5
```
{AI12-0112-1} function ">" (Left : Key_Type; Right : Cursor) return Boolean
   with Pre    => Right /= No_Element or else raise Constraint_Error,
           Global => in all;
```

92/2 {*AI95-00302-03*} Equivalent to Key (Right) < Left.

93/5
```
{AI12-0112-1} procedure Reverse_Iterate
  (Container : in Map;
   Process   : not null access procedure (Position : in Cursor))
   with Allows_Exit;
```

94/3 {*AI95-00302-03*} {*AI05-0212-1*} Iterates over the nodes in Container as per procedure Iterate, with the difference that the nodes are traversed in predecessor order, starting with the last node.

94.1/5
```
{AI12-0112-1} {AI12-0266-1} function Iterate (Container : in Map)
   return Map_Iterator_Interfaces.Parallel_Reversible_Iterator'Class
   with Post => Tampering_With_Cursors_Prohibited (Container);
```

94.2/5 {*AI05-0212-1*} {*AI05-0265-1*} {*AI05-0269-1*} {*AI12-0266-1*} Iterate returns an iterator object (see 5.5.1) that will generate a value for a loop parameter (see 5.5.2) designating each node in Container, starting with the first node and moving the cursor according to the successor relation when used as a forward iterator, and starting with the last node and moving the cursor according to the predecessor relation when used as a reverse iterator, and processing all nodes concurrently when used as a parallel iterator. Tampering with the cursors of Container is prohibited while the iterator object exists (in particular, in the sequence_of_statements of the loop_statement whose iterator_specification denotes this object). The iterator object needs finalization.

94.3/5
```
function Iterate (Container : in Map; Start : in Cursor)
   return Map_Iterator_Interfaces.Reversible_Iterator'Class
   with Pre  => (Start /= No_Element
                    or else raise Constraint_Error) and then
                (Has_Element (Container, Start)
                    or else raise Program_Error),
        Post => Tampering_With_Cursors_Prohibited (Container);
```

94.4/5 {*AI05-0262-1*} {*AI05-0265-1*} {*AI05-0269-1*} {*AI12-0112-1*} Iterate returns a reversible iterator object (see 5.5.1) that will generate a value for a loop parameter (see 5.5.2) designating each node in Container, starting with the node designated by Start and moving the cursor according to the successor relation when used as a forward iterator, or moving the cursor according to the predecessor relation when used as a reverse iterator. Tampering with the cursors of Container is prohibited while the iterator object exists (in particular, in the sequence_of_statements of the loop_statement whose iterator_specification denotes this object). The iterator object needs finalization.

Discussion: Exits are allowed from the loops created using the iterator objects. In particular, to stop the iteration at a particular cursor, just add 94.a/3

```
exit when Cur = Stop;
```
94.b/3

in the body of the loop (assuming that `Cur` is the loop parameter and `Stop` is the cursor that you want to stop at). 94.c/3

Implementation Advice

{*AI95-00302-03*} If *N* is the length of a map, then the worst-case time complexity of the Element, Insert, Include, Replace, Delete, Exclude, and Find operations that take a key parameter should be *O*((log *N*)**2) or better. The worst-case time complexity of the subprograms that take a cursor parameter should be *O*(1). 95/2

Implementation Advice: The worst-case time complexity of Element, Insert, Include, Replace, Delete, Exclude, and Find operations that take a key parameter for Containers.Ordered_Maps should be *O*((log *N*)**2) or better. The worst-case time complexity of the subprograms of Containers.Ordered_Maps that take a cursor parameter should be *O*(1). 95.a/2

Implementation Note: A balanced (red-black) tree for keys has *O*(log *N*) worst-case performance. Note that a *O*(*N*) worst-case implementation (like a list) would be wrong. 95.b/2

Reason: We do not mean to overly constrain implementation strategies here. However, it is important for portability that the performance of large containers has roughly the same factors on different implementations. If a program is moved to an implementation that takes *O*(*N*) to find elements, that program could be unusable when the maps are large. We allow the extra log *N* factors because the proportionality constant and caching effects are likely to be larger than the log factor, and we don't want to discourage innovative implementations. 95.c/2

Extensions to Ada 95

{*AI95-00302-03*} The generic package Containers.Ordered_Maps is new. 95.d/2

Incompatibilities With Ada 2005

{*AI05-0001-1*} Subprograms Assign and Copy are added to Containers.Ordered_Maps. If an instance of Containers.Ordered_Maps is referenced in a use_clause, and an entity *E* with the same defining_identifier as a new entity in Containers.Ordered_Maps is defined in a package that is also referenced in a use_clause, the entity *E* may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur. 95.e/3

Extensions to Ada 2005

{*AI05-0212-1*} Added iterator and indexing support to make ordered map containers more convenient to use. 95.f/3

Wording Changes from Ada 2005

{*AI05-0044-1*} **Correction:** Redefined "<" actuals to require a strict weak ordering; the old definition allowed indeterminant comparisons that would not have worked in a container. 95.g/3

{*AI05-0084-1*} **Correction:** Added a pragma Remote_Types so that containers can be used in distributed programs. 95.h/3

Incompatibilities With Ada 2012

{*AI12-0111-1*} {*AI12-0112-1*} {*AI12-0339-1*} A number of new subprograms, types, and even a nested package were added to Containers.Ordered_Maps to better support contracts and stable views. Therefore, a use clause conflict is possible; see the introduction of Annex A for more on this topic. 95.i/5

Extensions to Ada 2012

{*AI12-0212-1*} Maps now support named container aggregates, so aggregate syntax can be used to create Maps. 95.j/5

{*AI12-0266-1*} The iterator for the entire container now can return a parallel iterator which can be used to process the container in parallel. 95.k/5

Wording Changes from Ada 2012

{*AI12-0112-1*} Added contracts to this container. This includes describing some of the semantics with pre- and postconditions, rather than English text. Note that the preconditions can be Suppressed (see 11.5). 95.l/5

A.18.7 Sets

1/2 {*AI95-00302-03*} The language-defined generic packages Containers.Hashed_Sets and Containers.Ordered_Sets provide private types Set and Cursor, and a set of operations for each type. A set container allows elements of an arbitrary type to be stored without duplication. A hashed set uses a hash function to organize elements, while an ordered set orders its element per a specified relation.

2/3 {*AI95-00302-03*} {*AI05-0299-1*} This subclause describes the declarations that are common to both kinds of sets. See A.18.8 for a description of the semantics specific to Containers.Hashed_Sets and A.18.9 for a description of the semantics specific to Containers.Ordered_Sets.

Static Semantics

3/2 {*AI95-00302-03*} The actual function for the generic formal function "=" on Element_Type values is expected to define a reflexive and symmetric relationship and return the same result value each time it is called with a particular pair of values. If it behaves in some other manner, the function "=" on set values returns an unspecified value. The exact arguments and number of calls of this generic formal function by the function "=" on set values are unspecified.

3.a/2 **Ramification:** If the actual function for "=" is not symmetric and consistent, the result returned by the "=" for Set objects cannot be predicted. The implementation is not required to protect against "=" raising an exception, or returning random results, or any other “bad” behavior. And it can call "=" in whatever manner makes sense. But note that only the result of "=" for Set objects is unspecified; other subprograms are not allowed to break if "=" is bad (they aren't expected to use "=").

4/2 {*AI95-00302-03*} The type Set is used to represent sets. The type Set needs finalization (see 7.6).

5/2 {*AI95-00302-03*} A set contains elements. Set cursors designate elements. There exists an equivalence relation on elements, whose definition is different for hashed sets and ordered sets. A set never contains two or more equivalent elements. The *length* of a set is the number of elements it contains.

6/2 {*AI95-00302-03*} Each nonempty set has two particular elements called the *first element* and the *last element* (which may be the same). Each element except for the last element has a *successor element*. If there are no other intervening operations, starting with the first element and repeatedly going to the successor element will visit each element in the set exactly once until the last element is reached. The exact definition of these terms is different for hashed sets and ordered sets.

7/5 {*AI95-00302-03*} {*AI12-0111-1*} {*AI12-0112-1*} [Some operations check for “tampering with cursors” of a container because they depend on the set of elements of the container remaining constant and on elements of the container not being replaced.] When tampering with cursors is *prohibited* for a particular set object *S*, Program_Error is propagated by the finalization of *S*[, as well as by a call that passes *S* to certain of the operations of this package, as indicated by the precondition of such an operation].

7.a/5 **Discussion:** {*AI12-0112-1*} Note that Replace_Element tampers with cursors because it might delete and reinsert the element if it moves in the set. That could change the order of iteration, which is what this check is designed to prevent. Replace also tampers with cursors, as it is defined in terms of Replace_Element.

7.b/5 {*AI12-0112-1*} These inclusions mean that there are no operations that would tamper with elements that do not tamper with cursors. As such, we do not define tampering with elements at all for set containers. Earlier versions of Ada did so just so the description of subprograms are the same between containers, but since we've changed those to pre- and postconditions which are necessarily specific to each container, there no longer seems to be any reason to define tampering with elements for sets.

Paragraphs 8 through 14 are removed as preconditions now describe these rules.

10.a/3 **Ramification:** We don't need to explicitly mention assignment_statement, because that finalizes the target object as part of the operation, and finalization of an object is already defined as tampering with cursors.

15/2 {*AI95-00302-03*} Empty_Set represents the empty Set object. It has a length of 0. If an object of type Set is not otherwise initialized, it is initialized to the same value as Empty_Set.

{*AI95-00302-03*} No_Element represents a cursor that designates no element. If an object of type Cursor is not otherwise initialized, it is initialized to the same value as No_Element. 16/2

{*AI95-00302-03*} {*AI12-0434-1*} The primitive "=" operator for type Cursor returns True if both cursors are No_Element, or designate the same element in the same container. 17/5

To be honest: {*AI12-0434-1*} "The primitive "=" operator" is the one with two parameters of type Cursor which returns Boolean. We're not talking about some other (hidden) primitive function named "=". 17.a/5

{*AI95-00302-03*} Execution of the default implementation of the Input, Output, Read, or Write attribute of type Cursor raises Program_Error. 18/2

Reason: A cursor will probably be implemented in terms of one or more access values, and the effects of streaming access values is unspecified. Rather than letting the user stream junk by accident, we mandate that streaming of cursors raise Program_Error by default. The attributes can always be specified if there is a need to support streaming. 18.a/2

{*AI05-0001-1*} {*AI05-0262-1*} {*AI12-0437-1*} Set'Write for a Set object *S* writes Length(*S*) elements of the set to the stream. It may also write additional information about the set. 18.1/5

{*AI05-0001-1*} {*AI05-0262-1*} Set'Read reads the representation of a set from the stream, and assigns to *Item* a set with the same length and elements as was written by Set'Write. 18.2/3

Ramification: Streaming more elements than the container length is wrong. For implementation implications of this rule, see the Implementation Note in A.18.2. 18.b/3

```
{AI12-0112-1} function Has_Element (Position : Cursor) return Boolean
   with Nonblocking, Global => in all, Use_Formal => null;
```
18.3/5

{*AI05-0212-1*} Returns True if Position designates an element, and returns False otherwise. 18.4/3

To be honest: {*AI05-0005-1*} {*AI05-0212-1*} This function might not detect cursors that designate deleted elements; such cursors are invalid (see below) and the result of calling Has_Element with an invalid cursor is unspecified (but not erroneous). 18.c/3

```
{AI12-0112-1} function Has_Element (Container : Set; Position : Cursor)
   return Boolean
   with Nonblocking, Global => null, Use_Formal => null;
```
18.5/5

{*AI12-0112-1*} Returns True if Position designates an element in Container, and returns False otherwise. 18.6/5

Ramification: {*AI12-0112-1*} If Position is No_Element, Has_Element returns False. 18.d/5

```
function "=" (Left, Right : Set) return Boolean;
```
19/2

{*AI95-00302-03*} If Left and Right denote the same set object, then the function returns True. If Left and Right have different lengths, then the function returns False. Otherwise, for each element *E* in Left, the function returns False if an element equal to *E* (using the generic formal equality operator) is not present in Right. If the function has not returned a result after checking all of the elements, it returns True. Any exception raised during evaluation of element equality is propagated. 20/2

Implementation Note: This wording describes the canonical semantics. However, the order and number of calls on the formal equality function is unspecified for all of the operations that use it in this package, so an implementation can call it as many or as few times as it needs to get the correct answer. Specifically, there is no requirement to call the formal equality additional times once the answer has been determined. 20.a/2

```
function Equivalent_Sets (Left, Right : Set) return Boolean;
```
21/2

{*AI95-00302-03*} If Left and Right denote the same set object, then the function returns True. If Left and Right have different lengths, then the function returns False. Otherwise, for each element *E* in Left, the function returns False if an element equivalent to *E* is not present in Right. If the function has not returned a result after checking all of the elements, it returns True. Any exception raised during evaluation of element equivalence is propagated. 22/2

22.1/5
```
function Tampering_With_Cursors_Prohibited
   (Container : Set) return Boolean
   with Nonblocking, Global => null, Use_Formal => null;
```

22.2/5 {*AI12-0112-1*} Returns True if tampering with cursors is currently prohibited for Container, and returns False otherwise.

22.a/5 **Implementation Note:** {*AI12-0112-1*} Various contracts elsewhere in this specification require that this function be implemented with synchronized data. Moreover, it is possible for tampering to be prohibited by multiple operations (sequentially or in parallel). Therefore, tampering needs to be implemented with an atomic or protected counter. The counter is initialized to zero, and is incremented when tampering is prohibited, and decremented when leaving an area that prohibited tampering. Function Tampering_With_Cursors_Prohibited returns True if the counter is nonzero. (Note that any case where the result is not well-defined for one task is incorrect use of shared variables and would be erroneous by the rules of 9.10, so no special protection is needed to read the counter.)

23/5
```
{AI12-0112-1} function To_Set (New_Item : Element_Type) return Set
   with Post => Length (To_Set'Result) = 1 and then
                not Tampering_with_Cursors_Prohibited (To_Set'Result);
```

24/2 {*AI95-00302-03*} Returns a set containing the single element New_Item.

25/5
```
{AI12-0112-1} function Length (Container : Set) return Count_Type
   with Nonblocking, Global => null, Use_Formal => null;
```

26/2 {*AI95-00302-03*} Returns the number of elements in Container.

27/5
```
function Is_Empty (Container : Set) return Boolean
   with Nonblocking, Global => null, Use_Formal => null,
        Post => Is_Empty'Result = (Length (Container) = 0);
```

28/5 {*AI95-00302-03*} {*AI12-0112-1*} Returns True if Container is empty.

29/5
```
{AI12-0112-1} procedure Clear (Container : in out Set)
   with Pre  => not Tampering_With_Cursors_Prohibited (Container)
                    or else raise Program_Error,
        Post => Length (Container) = 0;
```

30/2 {*AI95-00302-03*} Removes all the elements from Container.

31/5
```
function Element (Position : Cursor) return Element_Type
   with Pre  => Position /= No_Element or else raise Constraint_Error,
        Nonblocking, Global => in all, Use_Formal => Element_Type;
```

32/5 {*AI95-00302-03*} {*AI12-0112-1*} Element returns the element designated by Position.

32.1/5
```
function Element (Container : Set;
                  Position  : Cursor) return Element_Type
   with Pre  => (Position /= No_Element
                    or else raise Constraint_Error) and then
                (Has_Element (Container, Position)
                   or else raise Program_Error),
        Nonblocking, Global => null, Use_Formal => Element_Type;
```

32.2/5 {*AI12-0112-1*} Element returns the element designated by Position.

33/5
```
procedure Replace_Element (Container : in out Set;
                           Position  : in     Cursor;
                           New_item  : in     Element_Type)
   with Pre  => (not Tampering_With_Elements_Prohibited (Container)
                    or else raise Program_Error) and then
                (Position /= No_Element
                   or else raise Constraint_Error) and then
                (Has_Element (Container, Position)
                   or else raise Program_Error);
```

34/5 {*AI95-00302-03*} {*AI12-0112-1*} {*AI12-0196-1*} Replace_Element assigns New_Item to the element designated by Position. Any exception raised by the assignment is propagated. For the

purposes of determining whether the parameters overlap in a call to Replace_Element, the Container parameter is not considered to overlap with any object [(including itself)].

Implementation Note: The final assignment may require that the node of the element be moved in the Set's data structures. That could mean that implementing this operation exactly as worded above could require the overhead of searching twice. Implementations are encouraged to avoid this extra overhead when possible, by prechecking if the old element is equivalent to the new one, by inserting a placeholder node while checking for an equivalent element, and similar optimizations. 34.a/2

The cursor still designates the same element after this operation; only the value of that element has changed. Cursors cannot include information about the relative position of an element in a Set (as they must survive insertions and deletions of other elements), so this should not pose an implementation hardship. 34.b/2

```
procedure Query_Element                                                    35/5
  (Position : in Cursor;
   Process  : not null access procedure (Element : in Element_Type))
   with Pre  => Position /= No_Element
                   or else raise Constraint_Error,
        Global => in all;
```

{*AI95-00302-03*} {*AI05-0021-1*} {*AI05-0265-1*} {*AI12-0112-1*} Query_Element calls Process.**all** with the element designated by Position as the argument. Tampering with the elements of the set that contains the element designated by Position is prohibited during the execution of the call on Process.**all**. Any exception raised by Process.**all** is propagated. 36/5

```
procedure Query_Element                                                    36.1/5
  (Container : in Set;
   Position  : in Cursor;
   Process  : not null access procedure (Element : in Element_Type))
   with Pre  => (Position /= No_Element
                   or else raise Constraint_Error) and then
                (Has_Element (Container, Position)
                   or else raise Program_Error);
```

{*AI12-0112-1*} Query_Element calls Process.**all** with the key and element from the node designated by Position as the arguments. Tampering with the elements of Container is prohibited during the execution of the call on Process.**all**. Any exception raised by Process.**all** is propagated. 36.2/5

```
{AI12-0112-1} type Constant_Reference_Type                                 36.3/5
      (Element : not null access constant Element_Type) is private
   with Implicit_Dereference => Element,
        Nonblocking, Global => in out synchronized,
        Default_Initial_Condition => (raise Program_Error);
```

{*AI05-0212-1*} The type Constant_Reference_Type needs finalization. 36.4/3

This paragraph was deleted.{*AI12-0112-1*} 36.5/5

Reason: It is expected that Constant_Reference_Type will be a controlled type, for which finalization will have some action to terminate the tampering check for the associated container. If the object is created by default, however, there is no associated container. Since this is useless, and supporting this case would take extra work, we define it to raise an exception. 36.a/3

```
{AI12-0112-1} function Constant_Reference (Container : aliased in Set;    36.6/5
                                           Position  : in Cursor)
   return Constant_Reference_Type
   with Pre  => (Position /= No_Element
                   or else raise Constraint_Error) and then
                (Has_Element (Container, Position)
                   or else raise Program_Error),
        Post => Tampering_With_Cursors_Prohibited (Container),
        Nonblocking, Global => null, Use_Formal => null;
```

{*AI05-0212-1*} {*AI05-0269-1*} This function (combined with the Constant_Indexing and Implicit_Dereference aspects) provides a convenient way to gain read access to an individual element of a set given a cursor. 36.7/3

36.8/5 {*AI05-0212-1*} {*AI05-0265-1*} {*AI12-0112-1*} Constant_Reference returns an object whose discriminant is an access value that designates the element designated by Position. Tampering with the cursors of Container is prohibited while the object returned by Constant_Reference exists and has not been finalized.

36.9/5
```
{AI12-0112-1} procedure Assign (Target : in out Set; Source : in Set)
   with Pre  => not Tampering_With_Cursors_Prohibited (Target)
                   or else raise Program_Error,
        Post => Length (Source) = Length (Target);
```

36.10/3 {*AI05-0001-1*} {*AI05-0248-1*} If Target denotes the same object as Source, the operation has no effect. Otherwise, the elements of Source are copied to Target as for an assignment_statement assigning Source to Target.

36.b/3 **Discussion:** {*AI05-0005-1*} This routine exists for compatibility with the bounded set containers. For an unbounded set, `Assign(A, B)` and `A := B` behave identically. For a bounded set, := will raise an exception if the container capacities are different, while Assign will not raise an exception if there is enough room in the target.

37/5
```
{AI12-0112-1} procedure Move (Target : in out Set;
                              Source : in out Set)
   with Pre  => (not Tampering_With_Cursors_Prohibited (Target)
                    or else raise Program_Error) and then
                (not Tampering_With_Cursors_Prohibited (Source)
                    or else raise Program_Error),
        Post => (if not Target'Has_Same_Storage (Source) then
                    Length (Target) = Length (Source'Old) and then
                    Length (Source) = 0);
```

38/3 {*AI95-00302-03*} {*AI05-0001-1*} {*AI05-0248-1*} {*AI05-0262-1*} If Target denotes the same object as Source, then the operation has no effect. Otherwise, the operation is equivalent to Assign (Target, Source) followed by Clear (Source).

39/5
```
{AI12-0112-1} procedure Insert (Container : in out Set;
                                New_Item  : in     Element_Type;
                                Position  :    out Cursor;
                                Inserted  :    out Boolean)
   with Pre  => (not Tampering_With_Elements_Prohibited (Container)
                    or else raise Program_Error) and then
                (Length (Container) <= Count_Type'Last - 1
                    or else raise Constraint_Error),
        Post => (declare
                    Original_Length : constant Count_Type :=
                       Length (Container)'Old;
                 begin
                    Has_Element (Container, Position) and then
                   (if Inserted then
                      Length (Container) = Original_Length + 1
                    else
                      Length (Container) = Original_Length));
```

40/2 {*AI95-00302-03*} Insert checks if an element equivalent to New_Item is already present in Container. If a match is found, Inserted is set to False and Position designates the matching element. Otherwise, Insert adds New_Item to Container; Inserted is set to True and Position designates the newly-inserted element. Any exception raised during allocation is propagated and Container is not modified.

41/5
```
{AI12-0112-1} procedure Insert (Container : in out Set;
                    New_Item  : in     Element_Type)
   with Pre  => (not Tampering_With_Cursors_Prohibited (Container)
                     or else raise Program_Error) and then
                (Length (Container) <= Count_Type'Last - 1
                     or else raise Constraint_Error),
        Post => Length (Container) = Length (Container)'Old + 1;
```

42/2
{*AI95-00302-03*} Insert inserts New_Item into Container as per the four-parameter Insert, with the difference that if an element equivalent to New_Item is already in the set, then Constraint_Error is propagated.

42.a/2
Discussion: This is equivalent to:

42.b/2
```
declare
  Inserted : Boolean; C : Cursor;
begin
  Insert (Container, New_Item, C, Inserted);
  if not Inserted then
     raise Constraint_Error;
  end if;
end;
```

42.c/2
but doesn't require the hassle of **out** parameters.

43/5
```
{AI12-0112-1} procedure Include (Container : in out Set;
                    New_Item  : in     Element_Type)
   with Pre  => (not Tampering_With_Cursors_Prohibited (Container)
                     or else raise Program_Error) and then
                (Length (Container) <= Count_Type'Last - 1
                     or else raise Constraint_Error),
        Post => (declare
                   Original_Length : constant Count_Type :=
                      Length (Container)'Old;
                 begin
                   Length (Container)
                      in Original_Length | Original_Length + 1);
```

44/2
{*AI95-00302-03*} Include inserts New_Item into Container as per the four-parameter Insert, with the difference that if an element equivalent to New_Item is already in the set, then it is replaced. Any exception raised during assignment is propagated.

45/5
```
{AI12-0112-1} procedure Replace (Container : in out Set;
                    New_Item  : in     Element_Type)
   with Pre  => not Tampering_With_Cursors_Prohibited (Container)
                     or else raise Program_Error,
        Post => Length (Container) = Length (Container)'Old;
```

46/2
{*AI95-00302-03*} Replace checks if an element equivalent to New_Item is already in the set. If a match is found, that element is replaced with New_Item; otherwise, Constraint_Error is propagated.

47/5
```
{AI12-0112-1} procedure Exclude (Container : in out Set;
                    Item       : in     Element_Type)
   with Pre  => not Tampering_With_Cursors_Prohibited (Container)
                     or else raise Program_Error,
        Post => (declare
                   Original_Length : constant Count_Type :=
                      Length (Container)'Old;
                 begin
                   Length (Container) in
                      Original_Length - 1 | Original_Length);
```

48/2
{*AI95-00302-03*} Exclude checks if an element equivalent to Item is present in Container. If a match is found, Exclude removes the element from the set.

49/5
```
{AI12-0112-1} procedure Delete (Container : in out Set;
                                Item      : in     Element_Type)
   with Pre  => not Tampering_With_Cursors_Prohibited (Container)
                    or else raise Program_Error,
        Post => Length (Container) = Length (Container)'Old - 1;
```

50/2 {*AI95-00302-03*} Delete checks if an element equivalent to Item is present in Container. If a match is found, Delete removes the element from the set; otherwise, Constraint_Error is propagated.

51/5
```
procedure Delete (Container : in out Set;
                  Position  : in out Cursor)
   with Pre  => (not Tampering_With_Cursors_Prohibited (Container)
                    or else raise Program_Error) and then
                (Position /= No_Element
                    or else raise Constraint_Error) and then
                (Has_Element (Container, Position)
                   or else raise Program_Error),
        Post => Length (Container) = Length (Container)'Old - 1 and then
                Position = No_Element;
```

52/5 {*AI95-00302-03*} {*AI12-0112-1*} Delete removes the element designated by Position from the set.

52.a/2 **Ramification:** The check on Position checks that the cursor does not belong to some other set. This check implies that a reference to the set is included in the cursor value. This wording is not meant to require detection of dangling cursors; such cursors are defined to be invalid, which means that execution is erroneous, and any result is allowed (including not raising an exception).

53/5
```
{AI12-0112-1} procedure Union (Target : in out Set;
                               Source : in     Set)
   with Pre  => not Tampering_With_Cursors_Prohibited (Target)
                   or else raise Program_Error,
        Post => Length (Target) <= Length (Target)'Old + Length (Source);
```

54/2 {*AI95-00302-03*} Union inserts into Target the elements of Source that are not equivalent to some element already in Target.

54.a/2 **Implementation Note:** If the objects are the same, the result is the same as the original object. The implementation needs to take care so that aliasing effects do not make the result trash; Union (S, S); must work.

55/5
```
{AI12-0112-1} function Union (Left, Right : Set) return Set
   with Post => Length (Union'Result) <=
                   Length (Left) + Length (Right) and then
                not Tampering_With_Cursors_Prohibited (Union'Result);
```

56/2 {*AI95-00302-03*} Returns a set comprising all of the elements of Left, and the elements of Right that are not equivalent to some element of Left.

57/5
```
{AI12-0112-1} procedure Intersection (Target : in out Set;
                                      Source : in     Set)
   with Pre  => not Tampering_With_Cursors_Prohibited (Target)
                   or else raise Program_Error,
        Post => Length (Target) <= Length (Target)'Old + Length (Source);
```

58.a/2 **Implementation Note:** If the objects are the same, the result is the same as the original object. The implementation needs to take care so that aliasing effects do not make the result trash; Intersection (S, S); must work.

```
{AI12-0112-1} function Intersection (Left, Right : Set) return Set                    59/5
   with Post => Length (Intersection'Result) <=
                   Length (Left) + Length (Right) and then
                not Tampering_With_Cursors_Prohibited (Intersection'Result);
```

{*AI95-00302-03*} Returns a set comprising all the elements of Left that are equivalent to the some element of Right. 60/2

```
{AI12-0112-1} procedure Difference (Target : in out Set;                              61/5
                       Source : in     Set)
   with Pre  => not Tampering_With_Cursors_Prohibited (Target)
                   or else raise Program_Error,
        Post => Length (Target) <= Length (Target)'Old + Length (Source);
```

{*AI95-00302-03*} If Target denotes the same object as Source, then Difference clears Target. Otherwise, it deletes from Target the elements that are equivalent to some element of Source. 62/2

```
{AI12-0112-1} function Difference (Left, Right : Set) return Set                      63/5
   with Post => Length (Difference'Result) <= Length (Left) +
                   Length (Right) and then
                not Tampering_With_Cursors_Prohibited (Difference'Result);
```

{*AI95-00302-03*} Returns a set comprising the elements of Left that are not equivalent to some element of Right. 64/2

```
{AI12-0112-1} procedure Symmetric_Difference (Target : in out Set;                    65/5
                              Source : in     Set)
   with Pre  => not Tampering_With_Cursors_Prohibited (Target)
                   or else raise Program_Error,
        Post => Length (Target) <= Length (Target)'Old + Length (Source);
```

{*AI95-00302-03*} If Target denotes the same object as Source, then Symmetric_Difference clears Target. Otherwise, it deletes from Target the elements that are equivalent to some element of Source, and inserts into Target the elements of Source that are not equivalent to some element of Target. 66/2

```
{AI12-0112-1} function Symmetric_Difference (Left, Right : Set) return Set            67/5
   with Post => Length (Symmetric_Difference'Result) <=
                   Length (Left) + Length (Right) and then
                not Tampering_With_Cursors_Prohibited (
                   Symmetric_Difference'Result);
```

{*AI95-00302-03*} Returns a set comprising the elements of Left that are not equivalent to some element of Right, and the elements of Right that are not equivalent to some element of Left. 68/2

```
function Overlap (Left, Right : Set) return Boolean;                                  69/2
```

{*AI95-00302-03*} {*AI05-0264-1*} If an element of Left is equivalent to some element of Right, then Overlap returns True. Otherwise, it returns False. 70/3

Discussion: This operation is commutative. If Overlap returns False, the two sets are disjoint. 70.a/2

```
function Is_Subset (Subset : Set;                                                     71/2
                    Of_Set : Set) return Boolean;
```

{*AI95-00302-03*} {*AI05-0264-1*} If an element of Subset is not equivalent to some element of Of_Set, then Is_Subset returns False. Otherwise, it returns True. 72/3

Discussion: This operation is not commutative, so we use parameter names that make it clear in named notation which set is which. 72.a/2

73/5
```
{AI12-0112-1} function First (Container : Set) return Cursor
   with Nonblocking, Global => null, Use_Formal => null,
        Post => (if not Is_Empty (Container)
                 then Has_Element (Container, First'Result)
                 else First'Result = No_Element);
```

74/2 {*AI95-00302-03*} If Length (Container) = 0, then First returns No_Element. Otherwise, First returns a cursor that designates the first element in Container.

75/5
```
{AI12-0112-1} function Next (Position : Cursor) return Cursor
   with Nonblocking, Global => in all, Use_Formal => null,
        Post => (if Position = No_Element then Next'Result = No_Element);
```

76/2 {*AI95-00302-03*} Returns a cursor that designates the successor of the element designated by Position. If Position designates the last element, then No_Element is returned. If Position equals No_Element, then No_Element is returned.

76.1/5
```
function Next (Container : Set;
               Position  : Cursor) return Cursor
   with Nonblocking, Global => null, Use_Formal => null,
        Pre  => Position = No_Element or else
                Has_Element (Container, Position)
                   or else raise Program_Error,
        Post => (if Position = No_Element then Next'Result = No_Element
                 elsif Next'Result = No_Element then
                   Position = Last (Container)
                 else Has_Element (Container, Next'Result));
```

76.2/5 {*AI12-0112-1*} Returns a cursor designating the successor of the node designated by Position in Container.

77/5
```
{AI12-0112-1} procedure Next (Position : in out Cursor)
   with Nonblocking, Global => in all, Use_Formal => null;
```

78/2 {*AI95-00302-03*} Equivalent to Position := Next (Position).

78.1/5
```
procedure Next (Container : in     Set;
                Position  : in out Cursor)
   with Nonblocking, Global => null, Use_Formal => null,
        Pre  => Position = No_Element or else
                Has_Element (Container, Position)
                   or else raise Program_Error,
        Post => (if Position /= No_Element
                 then Has_Element (Container, Position));
```

78.2/5 {*AI12-0112-1*} Equivalent to Position := Next (Container, Position).

79/3 *This paragraph was deleted.*{*AI95-00302-03*} {*AI05-0004-1*}

80/5
```
{AI12-0112-1} function Find (Container : Set;
              Item      : Element_Type) return Cursor
      with Post => (if Find'Result /= No_Element
                    then Has_Element (Container, Find'Result));
```

81/2 {*AI95-00302-03*} If Length (Container) equals 0, then Find returns No_Element. Otherwise, Find checks if an element equivalent to Item is present in Container. If a match is found, a cursor designating the matching element is returned; otherwise, No_Element is returned.

82/2
```
function Contains (Container : Set;
                   Item      : Element_Type) return Boolean;
```

82.1/3 {*AI05-0004-1*} Equivalent to Find (Container, Item) /= No_Element.

Paragraphs 83 and 84 were moved above.

```
{AI12-0112-1} procedure Iterate                                                    85/5
  (Container : in Set;
   Process   : not null access procedure (Position : in Cursor))
   with Allows_Exit;
```

{*AI95-00302-03*} {*AI05-0265-1*} Iterate calls Process.**all** with a cursor that designates each element in Container, starting with the first element and moving the cursor according to the successor relation. Tampering with the cursors of Container is prohibited during the execution of a call on Process.**all**. Any exception raised by Process.**all** is propagated. 86/3

Implementation Note: The "tamper with cursors" check takes place when the operations that insert or delete elements, and so on are called. 86.a/2

See Iterate for vectors (A.18.2) for a suggested implementation of the check. 86.b/2

{*AI95-00302-03*} Both Containers.Hashed_Set and Containers.Ordered_Set declare a nested generic package Generic_Keys, which provides operations that allow set manipulation in terms of a key (typically, a portion of an element) instead of a complete element. The formal function Key of Generic_Keys extracts a key value from an element. It is expected to return the same value each time it is called with a particular element. The behavior of Generic_Keys is unspecified if Key behaves in some other manner. 87/2

{*AI95-00302-03*} A key is expected to unambiguously determine a single equivalence class for elements. The behavior of Generic_Keys is unspecified if the formal parameters of this package behave in some other manner. 88/2

```
{AI12-0112-1} function Key (Position : Cursor) return Key_Type                     89/5
   with Pre  => Position /= No_Element or else raise Constraint_Error,
        Global => in all;
```

{*AI95-00302-03*} Equivalent to Key (Element (Position)). 90/2

```
function Key (Container : Set;                                                     90.1/5
              Position : Cursor) return Key_Type
   with Pre  => (Position /= No_Element
                    or else raise Constraint_Error) and then
                 (Has_Element (Container, Position)
                    or else raise Program_Error);
```

{*AI12-0112-1*} Equivalent to Key (Element (Container, Position)). 90.2/5

{*AI95-00302-03*} The subprograms in package Generic_Keys named Contains, Find, Element, Delete, and Exclude, are equivalent to the corresponding subprograms in the parent package, with the difference that the Key parameter is used to locate an element in the set. 91/2

```
{AI12-0112-1} procedure Replace (Container : in out Set;                           92/5
                  Key       : in     Key_Type;
                  New_Item  : in     Element_Type)
   with Pre  => not Tampering_With_Cursors_Prohibited (Container)
                    or else raise Program_Error,
        Post => Length (Container) = Length (Container)'Old;
```

{*AI95-00302-03*} Equivalent to Replace_Element (Container, Find (Container, Key), New_Item). 93/2

94/5
```
procedure Update_Element_Preserving_Key
   (Container : in out Set;
    Position  : in     Cursor;
    Process   : not null access procedure
                                 (Element : in out Element_Type))
   with Pre  => (Position /= No_Element
                    or else raise Constraint_Error) and then
                (Has_Element (Container, Position)
                    or else raise Program_Error);
```

95/5 {*AI95-00302-03*} {*AI05-0265-1*} {*AI12-0112-1*} Update_Element_Preserving_Key uses Key to save the key value *K* of the element designated by Position. Update_Element_Preserving_Key then calls Process.**all** with that element as the argument. Tampering with the cursors of Container is prohibited during the execution of the call on Process.**all**. Any exception raised by Process.**all** is propagated. After Process.**all** returns, Update_Element_Preserving_Key checks if *K* determines the same equivalence class as that for the new element; if not, the element is removed from the set and Program_Error is propagated.

95.a/2 **Reason:** The key check ensures that the invariants of the set are preserved by the modification. The "tampers with the elements" check prevents data loss (if Element_Type is by-copy) or erroneous execution (if element type is unconstrained and indefinite).

96/2 If Element_Type is unconstrained and definite, then the actual Element parameter of Process.**all** shall be unconstrained.

96.a/2 **Ramification:** This means that the elements cannot be directly allocated from the heap; it must be possible to change the discriminants of the element in place.

96.1/5
```
{AI12-0112-1} type Reference_Type (Element : not null access Element_Type) is
private
   with Implicit_Dereference => Element,
        Nonblocking, Global => in out synchronized,
        Default_Initial_Condition => (raise Program_Error);
```

96.2/3 {*AI05-0212-1*} The type Reference_Type needs finalization.

96.3/5 *This paragraph was deleted.*{*AI12-0112-1*}

96.4/5
```
{AI12-0112-1} function Reference_Preserving_Key (Container : aliased in out Set;
                                                 Position  : in Cursor)
   return Reference_Type
   with Pre  => (Position /= No_Element
                    or else raise Constraint_Error) and then
                (Has_Element (Container, Position)
                    or else raise Program_Error),
        Post => Tampering_With_Cursors_Prohibited (Container);
```

96.5/3 {*AI05-0212-1*} {*AI05-0269-1*} This function (combined with the Implicit_Dereference aspect) provides a convenient way to gain read and write access to an individual element of a set given a cursor.

96.6/5 {*AI05-0212-1*} {*AI05-0265-1*} {*AI12-0112-1*} Reference_Preserving_Key uses Key to save the key value *K*; then returns an object whose discriminant is an access value that designates the element designated by Position. Tampering with the cursors of Container is prohibited while the object returned by Reference_Preserving_Key exists and has not been finalized. When the object returned by Reference_Preserving_Key is finalized, a check is made if *K* determines the same equivalence class as that for the new element; if not, the element is removed from the set and Program_Error is propagated.

```
{AI12-0112-1} function Constant_Reference (Container : aliased in Set;                    96.7/5
                                           Key       : in Key_Type)
   return Constant_Reference_Type
   with Pre  => Find (Container, Key) /= No_Element
                   or else raise Constraint_Error,
        Post => Tampering_With_Cursors_Prohibited (Container);
```

{*AI05-0212-1*} {*AI05-0269-1*} This function (combined with the Implicit_Dereference aspect) provides a convenient way to gain read access to an individual element of a set given a key value. 96.8/3

Equivalent to Constant_Reference (Container, Find (Container, Key)). 96.9/3

```
{AI12-0112-1} function Reference_Preserving_Key (Container : aliased in out Set;          96.10/5
                                                 Key       : in Key_Type)
   return Reference_Type
   with Pre  => Find (Container, Key) /= No_Element
                   or else raise Constraint_Error,
        Post => Tampering_With_Cursors_Prohibited (Container);
```

{*AI05-0212-1*} {*AI05-0269-1*} This function (combined with the Implicit_Dereference aspect) provides a convenient way to gain read and write access to an individual element of a set given a key value. 96.11/3

Equivalent to Reference_Preserving_Key (Container, Find (Container, Key)). 96.12/3

{*AI12-0111-1*} The nested package Stable provides a type Stable.Set that represents a *stable* set, which is one that cannot grow and shrink. Such a set can be created by calling the Copy function, or by establishing a *stabilized view* of an ordinary set. 96.13/5

{*AI12-0111-1*} The subprograms of the set package that have a parameter or result of type Set are included in the nested package Stable with the same specification, except that the following are omitted: 96.14/5

Tampering_With_Cursors_Prohibited, Assign, Move, Insert, Include, Clear, Delete, Exclude, Replace, Replace_Element, procedures Union, Intersection, Difference, and Symmetric_Difference, (for Ordered_sets) Delete_First and Delete_Last, and (for Hashed_sets) Reserve_Capacity 96.15/5

Discussion: The Generic_Keys package is not included in the Stable package. The functions Union, Intersection, Difference, and Symmetric_Difference are included in the Stable package. 96.a.1/5

Ramification: The names Set and Cursor mean the types declared in the nested package in these subprogram specifications. 96.a.2/5

Reason: The omitted routines are those that tamper with cursors (or test that state). The model is that it is impossible to tamper with cursors of a stable view since no such operations are included. Thus tampering checks are not needed for a stable view, and we omit the operations associated with those checks. 96.a.3/5

{*AI12-0111-1*} The operations of this package are equivalent to those for ordinary sets, except that the calls to Tampering_With_Cursors_Prohibited that occur in preconditions are replaced by False, and any that occur in postconditions are replaced by True. 96.16/5

{*AI12-0111-1*} {*AI12-0439-1*} If a stable set is declared with the Base discriminant designating a pre-existing ordinary set, the stable set represents a stabilized view of the underlying ordinary set, and any operation on the stable set is reflected on the underlying ordinary set. While a stabilized view exists, any operation that tampers with cursors performed on the underlying set is prohibited. The finalization of a stable set that provides such a view removes this restriction on the underlying ordinary set [(though some other restriction can exist due to other concurrent iterations or stabilized views)]. 96.17/5

{*AI12-0111-1*} {*AI12-0438-1*} If a stable set is declared without specifying Base, the object is necessarily initialized. The initializing expression of the stable set, [typically a call on Copy], determines the Length of the set. The Length of a stable set never changes after initialization. 96.18/5

Proof: {*AI12-0438-1*} Initialization is required as the type is indefinite, see 3.3.1. 96.b/5

Bounded (Run-Time) Errors

96.19/3 {*AI05-0022-1*} {*AI05-0248-1*} It is a bounded error for the actual function associated with a generic formal subprogram, when called as part of an operation of a set package, to tamper with elements of any set parameter of the operation. Either Program_Error is raised, or the operation works as defined on the value of the set either prior to, or subsequent to, some or all of the modifications to the set.

96.20/3 {*AI05-0027-1*} It is a bounded error to call any subprogram declared in the visible part of a set package when the associated container has been finalized. If the operation takes Container as an **in out** parameter, then it raises Constraint_Error or Program_Error. Otherwise, the operation either proceeds as it would for an empty container, or it raises Constraint_Error or Program_Error.

Erroneous Execution

97/2 {*AI95-00302-03*} A Cursor value is *invalid* if any of the following have occurred since it was created:

98/2 • The set that contains the element it designates has been finalized;

98.1/3 • {*AI05-0160-1*} The set that contains the element it designates has been used as the Target of a call to Assign, or as the target of an assignment_statement;

99/2 • The set that contains the element it designates has been used as the Source or Target of a call to Move; or

100/3 • {*AI05-0160-1*} {*AI05-0262-1*} The element it designates has been removed from the set that previously contained the element.

100.a/3 **Ramification:** {*AI05-0160-1*} This can happen directly via calls to Clear, Exclude, Delete, and Update_Element_Preserving_Key, and indirectly via calls to procedures Intersection, Difference, and Symmetric_Difference.

101/2 {*AI95-00302-03*} The result of "=" or Has_Element is unspecified if these functions are called with an invalid cursor parameter. Execution is erroneous if any other subprogram declared in Containers.Hashed_Sets or Containers.Ordered_Sets is called with an invalid cursor parameter.

101.a/2 **Discussion:** The list above is intended to be exhaustive. In other cases, a cursor value continues to designate its original element. For instance, cursor values survive the insertion and deletion of other elements.

101.b/2 While it is possible to check for these cases, in many cases the overhead necessary to make the check is substantial in time or space. Implementations are encouraged to check for as many of these cases as possible and raise Program_Error if detected.

101.1/3 {*AI05-0212-1*} Execution is erroneous if the set associated with the result of a call to Reference or Constant_Reference is finalized before the result object returned by the call to Reference or Constant_Reference is finalized.

101.c/3 **Reason:** Each object of Reference_Type and Constant_Reference_Type probably contains some reference to the originating container. If that container is prematurely finalized (which is only possible via Unchecked_Deallocation, as accessibility checks prevent passing a container to Reference that will not live as long as the result), the finalization of the object of Reference_Type will try to access a nonexistent object. This is a normal case of a dangling pointer created by Unchecked_Deallocation; we have to explicitly mention it here as the pointer in question is not visible in the specification of the type. (This is the same reason we have to say this for invalid cursors.)

Implementation Requirements

102/5 {*AI95-00302-03*} {*AI12-0437-1*} No storage associated with a set object shall be lost upon assignment or scope exit.

103/3 {*AI95-00302-03*} {*AI05-0262-1*} The execution of an assignment_statement for a set shall have the effect of copying the elements from the source set object to the target set object and changing the length of the target object to that of the source object.

103.a/3 **Implementation Note:** {*AI05-0298-1*} An assignment of a Set is a “deep” copy; that is the elements are copied as well as the data structures. We say “effect of” in order to allow the implementation to avoid copying elements immediately

if it wishes. For instance, an implementation that avoided copying until one of the containers is modified would be allowed. (Note that this implementation would require care, see A.18.2 for more.)

Implementation Advice

{*AI95-00302-03*} Move should not copy elements, and should minimize copying of internal data structures. 104/2

Implementation Advice: Move for sets should not copy elements, and should minimize copying of internal data structures. 104.a/2

Implementation Note: Usually that can be accomplished simply by moving the pointer(s) to the internal data structures from the Source container to the Target container. 104.b/2

{*AI95-00302-03*} If an exception is propagated from a set operation, no storage should be lost, nor any elements removed from a set unless specified by the operation. 105/2

Implementation Advice: If an exception is propagated from a set operation, no storage should be lost, nor any elements removed from a set unless specified by the operation. 105.a/2

Reason: This is important so that programs can recover from errors. But we don't want to require heroic efforts, so we just require documentation of cases where this can't be accomplished. 105.b/2

Wording Changes from Ada 95

{*AI95-00302-03*} This description of sets is new; the extensions are documented with the specific packages. 105.c/2

Extensions to Ada 2005

{*AI05-0212-1*} Added reference support to make set containers more convenient to use. 105.d/3

Wording Changes from Ada 2005

{*AI05-0001-1*} Added procedure Assign; the extension and incompatibility is documented with the specific packages. 105.e/3

{*AI05-0001-1*} Generalized the definition of Move. Specified which elements are read/written by stream attributes. 105.f/3

{*AI05-0022-1*} **Correction:** Added a Bounded (Run-Time) Error to cover tampering by generic actual subprograms. 105.g/3

{*AI05-0027-1*} **Correction:** Added a Bounded (Run-Time) Error to cover access to finalized set containers. 105.h/3

{*AI05-0160-1*} **Correction:** Revised the definition of invalid cursors to cover missing (and new) cases. 105.i/3

{*AI05-0265-1*} **Correction:** Defined when a container prohibits tampering in order to more clearly define where the check is made and the exception raised. 105.j/3

Inconsistencies With Ada 2012

{*AI12-0111-1*} Procedures Union, Intersection, Difference, and Symmeteric_Difference are now defined to tamper with the cursors of the Target parameter. A program which attempts to use one of these operations while tampering is prohibited will raise Program_Error. However, since the operations do modify the container, the effects would have been unpredictable, so this change will likely fix bugs. 105.k/5

Extensions to Ada 2012

{*AI12-0196-1*} **Correction:** Replace_Element is now defined such that it can be used concurrently so long as it operates on different elements. This allows some container operations to be used in parallel without separate synchronization. 105.l/5

Wording Changes from Ada 2012

{*AI12-0110-1*} **Corrigendum:** Clarified that tampering checks precede all other checks made by a subprogram (but come after those associated with the call). 105.m/4

{*AI12-0112-1*} Added contracts to this container. This includes describing some of the semantics with pre- and postconditions, rather than English text. Note that the preconditions can be Suppressed (see 11.5). 105.n/5

A.18.8 The Generic Package Containers.Hashed_Sets

Static Semantics

1/2 {*AI95-00302-03*} The generic library package Containers.Hashed_Sets has the following declaration:

2/5
```
{AI05-0084-1} {AI05-0212-1} {AI12-0112-1} with Ada.Iterator_Interfaces;
generic
   type Element_Type is private;
   with function Hash (Element : Element_Type) return Hash_Type;
   with function Equivalent_Elements (Left, Right : Element_Type)
                 return Boolean;
   with function "=" (Left, Right : Element_Type) return Boolean is <>;
package Ada.Containers.Hashed_Sets
   with Preelaborate, Remote_Types,
        Nonblocking, Global => in out synchronized is
```

2.a/5 **Discussion:** {*AI12-0112-1*} For discussion on the reasons and meaning of the specifications of the Global and Nonblocking aspects in this generic package, see the notes on the equivalent operations in the specification of the Containers.Vectors package (see A.18.2).

3/5
```
{AI05-0212-1} {AI12-0111-1} {AI12-0112-1} {AI12-0212-1} {AI12-0339-1} {AI12-0399-1}
type Set is tagged private
      with Constant_Indexing => Constant_Reference,
           Default_Iterator  => Iterate,
           Iterator_Element  => Element_Type,
           Iterator_View     => Stable.Set,
           Aggregate         => (Empty       => Empty,
                                 Add_Unnamed => Include),
           Stable_Properties => (Length,
                                 Tampering_With_Cursors_Prohibited),
           Default_Initial_Condition =>
              Length (Set) = 0 and then
              (not Tampering_With_Cursors_Prohibited (Set)),
           Preelaborable_Initialization;
```

3.a/5 **Discussion:** {*AI12-0112-1*} Unlike a Vector, the Stable_Properties of a Hashed_Set do not include the Capacity. If we had included it, some of the otherwise shared definitions would need different postconditions for Hashed_Sets and Ordered_Sets. If we were starting these containers from scratch, we probably would have approached the sharing of definitions differently so that we could avoid issues like this, but a major reorganization of this existing material would be too much change.

4/5
```
{AI12-0399-1}    type Cursor is private
      with Preelaborable_Initialization;
```

5/2
```
   Empty_Set : constant Set;
```

6/2
```
   No_Element : constant Cursor;
```

6.1/5
```
{AI05-0212-1} {AI12-0112-1}    function Has_Element (Position : Cursor) return
Boolean
      with Nonblocking, Global => in all, Use_Formal => null;
```

6.2/5
```
{AI12-0112-1}    function Has_Element (Container : Set; Position : Cursor)
      return Boolean
      with Nonblocking, Global => null, Use_Formal => null;
```

6.3/3
```
{AI05-0212-1}    package Set_Iterator_Interfaces is new
       Ada.Iterator_Interfaces (Cursor, Has_Element);
```

7/2
```
   function "=" (Left, Right : Set) return Boolean;
```

8/2
```
   function Equivalent_Sets (Left, Right : Set) return Boolean;
```

8.1/5
```
{AI12-0112-1}    function Tampering_With_Cursors_Prohibited
      (Container : Set) return Boolean
      with Nonblocking, Global => null, Use_Formal => null;
```

```
{AI12-0339-1}    function Empty (Capacity : Count_Type := implementation-defined)                8.2/5
      return Set
      with Post =>
              Capacity (Empty'Result) >= Capacity and then
              not Tampering_With_Cursors_Prohibited (Empty'Result) and then
              Length (Empty'Result) = 0;

{AI12-0112-1}    function To_Set (New_Item : Element_Type) return Set                            9/5
      with Post => Length (To_Set'Result) = 1 and then
                   not Tampering_with_Cursors_Prohibited (To_Set'Result);

{AI12-0112-1}    function Capacity (Container : Set) return Count_Type                           10/5
      with Nonblocking, Global => null, Use_Formal => null;

{AI12-0112-1}    procedure Reserve_Capacity (Container : in out Set;                             11/5
                             Capacity  : in     Count_Type)
      with Pre  => not Tampering_With_Cursors_Prohibited (Container)
                      or else raise Program_Error,
           Post => Container.Capacity >= Capacity;

{AI12-0112-1}    function Length (Container : Set) return Count_Type                             12/5
      with Nonblocking, Global => null, Use_Formal => null;

{AI12-0112-1}    function Is_Empty (Container : Set) return Boolean                              13/5
      with Nonblocking, Global => null, Use_Formal => null,
           Post => Is_Empty'Result = (Length (Container) = 0);

{AI12-0112-1}    procedure Clear (Container : in out Set)                                        14/5
      with Pre  => not Tampering_With_Cursors_Prohibited (Container)
                      or else raise Program_Error,
           Post => Capacity (Container) = Capacity (Container)'Old and then
                   Length (Container) = 0;

{AI12-0112-1}    function Element (Position : Cursor) return Element_Type                        15/5
      with Pre  => Position /= No_Element or else raise Constraint_Error,
           Nonblocking, Global => in all, Use_Formal => Element_Type;

{AI12-0112-1}    function Element (Container : Set;                                              15.1/5
                                   Position  : Cursor) return Element_Type
      with Pre  => (Position /= No_Element
                      or else raise Constraint_Error) and then
                   (Has_Element (Container, Position)
                      or else raise Program_Error),
           Nonblocking, Global => null, Use_Formal => Element_Type;

{AI12-0112-1}    procedure Replace_Element (Container : in out Set;                              16/5
                                            Position  : in     Cursor;
                                            New_item  : in     Element_Type)
      with Pre  => (not Tampering_With_Cursors_Prohibited (Container)
                      or else raise Program_Error) and then
                   (Position /= No_Element
                      or else raise Constraint_Error) and then
                   (Has_Element (Container, Position)
                      or else raise Program_Error);

{AI12-0112-1}    procedure Query_Element                                                         17/5
     (Position : in Cursor;
      Process  : not null access procedure (Element : in Element_Type))
      with Pre  => Position /= No_Element or else raise Constraint_Error,
           Global => in all;

{AI12-0112-1}    procedure Query_Element                                                         17.1/5
     (Container : in Set;
      Position  : in Cursor;
      Process   : not null access procedure (Element : in Element_Type))

```

{*AI95-00302-03*} An object of type Set contains an expandable hash table, which is used to provide direct access to elements. The *capacity* of an object of type Set is the maximum number of elements that can be inserted into the hash table prior to it being automatically expanded. 63/2

{*AI95-00302-03*} Two elements *E1* and *E2* are defined to be *equivalent* if Equivalent_Elements (*E1*, *E2*) returns True. 64/2

{*AI95-00302-03*} The actual function for the generic formal function Hash is expected to return the same value each time it is called with a particular element value. For any two equivalent elements, the actual for Hash is expected to return the same value. If the actual for Hash behaves in some other manner, the 65/2

behavior of this package is unspecified. Which subprograms of this package call Hash, and how many times they call it, is unspecified.

66/2 {*AI95-00302-03*} The actual function for the generic formal function Equivalent_Elements is expected to return the same value each time it is called with a particular pair of Element values. It should define an equivalence relationship, that is, be reflexive, symmetric, and transitive. If the actual for Equivalent_Elements behaves in some other manner, the behavior of this package is unspecified. Which subprograms of this package call Equivalent_Elements, and how many times they call it, is unspecified.

66.1/3 {*AI05-0044-1*} If the actual function for the generic formal function "=" returns True for any pair of nonequivalent elements, then the behavior of the container function "=" is unspecified.

67/2 {*AI95-00302-03*} If the value of an element stored in a set is changed other than by an operation in this package such that at least one of Hash or Equivalent_Elements give different results, the behavior of this package is unspecified.

67.a/2 **Discussion:** See A.18.5, “The Generic Package Containers.Hashed_Maps” for a suggested implementation, and for justification of the restrictions regarding Hash and Equivalent_Elements. Note that sets only need to store elements, not key/element pairs.

68/2 {*AI95-00302-03*} Which elements are the first element and the last element of a set, and which element is the successor of a given element, are unspecified, other than the general semantics described in A.18.7.

68.1/5
```
function Empty (Capacity : Count_Type := implementation-defined)
   return Set
   with Post =>
           Capacity (Empty'Result) >= Capacity and then
           not Tampering_With_Cursors_Prohibited (Empty'Result) and then
           Length (Empty'Result) = 0;
```

68.2/2 {*AI12-0339-1*} Returns an empty set.

69/5
```
{AI12-0112-1} function Capacity (Container : Set) return Count_Type
   with Nonblocking, Global => null, Use_Formal => null;
```

70/2 {*AI95-00302-03*} Returns the capacity of Container.

71/5
```
{AI12-0112-1} procedure Reserve_Capacity (Container : in out Set;
                          Capacity  : in     Count_Type)
   with Pre  => not Tampering_With_Cursors_Prohibited (Container)
                   or else raise Program_Error,
        Post => Container.Capacity >= Capacity;
```

72/2 {*AI95-00302-03*} Reserve_Capacity allocates a new hash table such that the length of the resulting set can become at least the value Capacity without requiring an additional call to Reserve_Capacity, and is large enough to hold the current length of Container. Reserve_Capacity then rehashes the elements in Container onto the new hash table. It replaces the old hash table with the new hash table, and then deallocates the old hash table. Any exception raised during allocation is propagated and Container is not modified.

73/5 *This paragraph was deleted.*{*AI12-0112-1*}

73.a/2 **Reason:** Reserve_Capacity tampers with the cursors, as rehashing probably will change the relationships of the elements in Container.

74/5
```
{AI12-0112-1} procedure Clear (Container : in out Set)
   with Pre  => not Tampering_With_Cursors_Prohibited (Container)
                   or else raise Program_Error,
        Post => Capacity (Container) = Capacity (Container)'Old and then
                Length (Container) = 0;
```

75/2 {*AI95-00302-03*} In addition to the semantics described in A.18.7, Clear does not affect the capacity of Container.

```
{AI12-0112-1} procedure Assign (Target : in out Set; Source : in Set)                    75.1/5
      with Pre  => not Tampering_With_Cursors_Prohibited (Target)
                     or else raise Program_Error,
           Post => Length (Source) = Length (Target) and then
                   Capacity (Target) >= Length (Source);
```

{*AI05-0001-1*} {*AI05-0248-1*} In addition to the semantics described in A.18.7, if the length of Source is greater than the capacity of Target, Reserve_Capacity (Target, Length (Source)) is called before assigning any elements. 75.2/3

```
function Copy (Source : Set; Capacity : Count_Type := 0)                                 75.3/5
   return Set
   with Pre  => Capacity = 0 or else Capacity >= Length (Source)
                  or else raise Capacity_Error,
        Post =>
           Length (Copy'Result) = Length (Source) and then
           not Tampering_With_Cursors_Prohibited (Copy'Result) and then
           Copy'Result.Capacity = (if Capacity = 0 then
              Length (Source) else Capacity);
```

{*AI05-0001-1*} {*AI12-0112-1*} Returns a set whose elements are initialized from the elements of Source. 75.4/5

```
{AI12-0112-1} procedure Insert (Container : in out Set;                                  76/5
                  New_Item  : in     Element_Type;
                  Position  :    out Cursor;
                  Inserted  :    out Boolean)
   with Pre  => (not Tampering_With_Cursors_Prohibited (Container)
                  or else raise Program_Error) and then
                (Length (Container) <= Count_Type'Last - 1
                  or else raise Constraint_Error),
        Post => (declare
                  Original_Length : constant Count_Type :=
                     Length (Container)'Old;
                 begin
                  Has_Element (Container, Position) and then
                  (if Inserted then
                     Length (Container) = Original_Length + 1
                   else
                     Length (Container) = Original_Length)) and then
                 Capacity (Container) >= Length (Container);
```

{*AI95-00302-03*} In addition to the semantics described in A.18.7, if Length (Container) equals Capacity (Container), then Insert first calls Reserve_Capacity to increase the capacity of Container to some larger value. 77/2

```
function First (Container : Set) return Cursor;                                          78/2
```

{*AI95-00302-03*} If Length (Container) = 0, then First returns No_Element. Otherwise, First returns a cursor that designates the first hashed element in Container. 79/2

```
{AI12-0112-1} function Equivalent_Elements (Left, Right : Cursor)                        80/5
   return Boolean
   with Pre    => (Left /= No_Element and then Right /= No_Element)
                    or else raise Constraint_Error,
        Global => in all;
```

{*AI95-00302-03*} Equivalent to Equivalent_Elements (Element (Left), Element (Right)). 81/2

```
{AI12-0112-1} function Equivalent_Elements (Left  : Cursor;                              82/5
                                            Right : Element_Type) return Boolean
   with Pre    => Left /= No_Element or else raise Constraint_Error,
        Global => in all;
```

{*AI95-00302-03*} Equivalent to Equivalent_Elements (Element (Left), Right). 83/2

84/5
```
{AI12-0112-1} function Equivalent_Elements (Left  : Element_Type;
                                            Right : Cursor) return Boolean
   with Pre    => Right /= No_Element or else raise Constraint_Error,
        Global => in all;
```

85/2 {*AI95-00302-03*} Equivalent to Equivalent_Elements (Left, Element (Right)).

85.1/5
```
{AI12-0112-1} {AI12-0266-1} function Iterate (Container : in Set)
   return Set_Iterator_Interfaces.Parallel_Iterator'Class
   with Post => Tampering_With_Cursors_Prohibited (Container);
```

85.2/5 {*AI05-0212-1*} {*AI05-0265-1*} {*AI05-0269-1*} {*AI12-0266-1*} Iterate returns an iterator object (see 5.5.1) that will generate a value for a loop parameter (see 5.5.2) designating each element in Container, starting with the first element and moving the cursor according to the successor relation when used as a forward iterator, and processing all nodes concurrently when used as a parallel iterator. Tampering with the cursors of Container is prohibited while the iterator object exists (in particular, in the sequence_of_statements of the loop_statement whose iterator_specification denotes this object). The iterator object needs finalization.

86/2 {*AI95-00302-03*} For any element *E*, the actual function for the generic formal function Generic_Keys.Hash is expected to be such that Hash (*E*) = Generic_Keys.Hash (Key (*E*)). If the actuals for Key or Generic_Keys.Hash behave in some other manner, the behavior of Generic_Keys is unspecified. Which subprograms of Generic_Keys call Generic_Keys.Hash, and how many times they call it, is unspecified.

87/2 {*AI95-00302-03*} For any two elements *E1* and *E2*, the boolean values Equivalent_Elements (*E1*, *E2*) and Equivalent_Keys (Key (*E1*), Key (*E2*)) are expected to be equal. If the actuals for Key or Equivalent_Keys behave in some other manner, the behavior of Generic_Keys is unspecified. Which subprograms of Generic_Keys call Equivalent_Keys, and how many times they call it, is unspecified.

Implementation Advice

88/2 {*AI95-00302-03*} If *N* is the length of a set, the average time complexity of the subprograms Insert, Include, Replace, Delete, Exclude, and Find that take an element parameter should be *O*(log *N*). The average time complexity of the subprograms that take a cursor parameter should be *O*(1). The average time complexity of Reserve_Capacity should be *O*(*N*).

88.a/2 **Implementation Advice:** The average time complexity of the Insert, Include, Replace, Delete, Exclude, and Find operations of Containers.Hashed_Sets that take an element parameter should be *O*(log *N*). The average time complexity of the subprograms of Containers.Hashed_Sets that take a cursor parameter should be *O*(1). The average time complexity of Containers.Hashed_Sets.Reserve_Capacity should be *O*(*N*).

88.b/2 **Implementation Note:** {*AI95-00302-03*} See A.18.5, “The Generic Package Containers.Hashed_Maps” for implementation notes regarding some of the operations of this package.

Extensions to Ada 95

88.c/2 {*AI95-00302-03*} The generic package Containers.Hashed_Sets is new.

Incompatibilities With Ada 2005

88.d/3 {*AI05-0001-1*} Subprograms Assign and Copy are added to Containers.Hashed_Sets. If an instance of Containers.Hashed_Sets is referenced in a use_clause, and an entity *E* with the same defining_identifier as a new entity in Containers.Hashed_Sets is defined in a package that is also referenced in a use_clause, the entity *E* may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur.

Extensions to Ada 2005

88.e/3 {*AI05-0212-1*} Added iterator and indexing support to make hashed set containers more convenient to use.

Wording Changes from Ada 2005

{*AI05-0044-1*} **Correction:** Added wording to require the formal function be such that equal elements are also equivalent. 88.f/3

{*AI05-0084-1*} **Correction:** Added a pragma Remote_Types so that containers can be used in distributed programs. 88.g/3

Incompatibilities With Ada 2012

{*AI12-0111-1*} {*AI12-0112-1*} {*AI12-0339-1*} A number of new subprograms, types, and even a nested package were added to Containers.Hashed_Sets to better support contracts and stable views. Therefore, a use clause conflict is possible; see the introduction of Annex A for more on this topic. 88.h/5

Extensions to Ada 2012

{*AI12-0212-1*} Sets now support positional container aggregates, so aggregate syntax can be used to create Sets. 88.i/5

{*AI12-0266-1*} The iterator for the container now can return a parallel iterator which can be used to process the container in parallel. 88.j/5

Wording Changes from Ada 2012

{*AI12-0112-1*} Added contracts to this container. This includes describing some of the semantics with pre- and postconditions, rather than English text. Note that the preconditions can be Suppressed (see 11.5). 88.k/5

A.18.9 The Generic Package Containers.Ordered_Sets

Static Semantics

{*AI95-00302-03*} The generic library package Containers.Ordered_Sets has the following declaration: 1/2

```
{AI05-0084-1} {AI05-0212-1} {AI12-0112-1} with Ada.Iterator_Interfaces;
generic
   type Element_Type is private;
   with function "<" (Left, Right : Element_Type) return Boolean is <>;
   with function "=" (Left, Right : Element_Type) return Boolean is <>;
package Ada.Containers.Ordered_Sets
   with Preelaborate, Remote_Types,
        Nonblocking, Global => in out synchronized is
```

2/5

Discussion: {*AI12-0112-1*} For discussion on the reasons and meaning of the specifications of the Global and Nonblocking aspects in this generic package, see the notes on the equivalent operations in the specification of the Containers.Vectors package (see A.18.2). 2.a/5

```
   function Equivalent_Elements (Left, Right : Element_Type) return Boolean;
```

3/2

```

78/2 {*AI95-00302-03*} Two elements *E1* and *E2* are *equivalent* if both *E1* < *E2* and *E2* < *E1* return False, using the generic formal "<" operator for elements. Function Equivalent_Elements returns True if Left and Right are equivalent, and False otherwise.

79/3 {*AI95-00302-03*} {*AI05-0044-1*} The actual function for the generic formal function "<" on Element_Type values is expected to return the same value each time it is called with a particular pair of key values. It should define a strict weak ordering relationship (see A.18). If the actual for "<" behaves in some other manner, the behavior of this package is unspecified. Which subprograms of this package call "<" and how many times they call it, is unspecified.

79.1/3 {*AI05-0044-1*} If the actual function for the generic formal function "=" returns True for any pair of nonequivalent elements, then the behavior of the container function "=" is unspecified.

80/2 {*AI95-00302-03*} If the value of an element stored in a set is changed other than by an operation in this package such that at least one of "<" or "=" give different results, the behavior of this package is unspecified.

80.a/2 **Discussion:** See A.18.6, “The Generic Package Containers.Ordered_Maps” for a suggested implementation, and for justification of the restrictions regarding "<" and "=". Note that sets only need to store elements, not key/element pairs.

81/3 {*AI95-00302-03*} {*AI05-0262-1*} The *first element* of a nonempty set is the one which is less than all the other elements in the set. The *last element* of a nonempty set is the one which is greater than all the other elements in the set. The *successor* of an element is the smallest element that is larger than the given element. The *predecessor* of an element is the largest element that is smaller than the given element. All comparisons are done using the generic formal "<" operator for elements.

81.1/5
```
{AI12-0112-1} function Copy (Source : Set) return Set
   with Post => Length (Copy'Result) = Length (Source) and then
                not Tampering_With_Cursors_Prohibited (Copy'Result);
```

81.2/3 {*AI05-0001-1*} Returns a set whose elements are initialized from the corresponding elements of Source.

82/5
```
{AI12-0112-1} procedure Delete_First (Container : in out Set)
   with Pre  => not Tampering_With_Cursors_Prohibited (Container)
                   or else raise Program_Error,
        Post => (declare
                   Original_Length : constant Count_Type :=
                      Length (Container)'Old;
                 begin
                   (if Original_Length = 0 then Length (Container) = 0
                    else Length (Container) = Original_Length - 1));

```

109/2 {*AI95-00302-03*} Equivalent to Left < Element (Right).

110/5
```
{AI12-0112-1} function ">" (Left : Element_Type; Right : Cursor) return Boolean
   with Pre    => Right /= No_Element or else raise Constraint_Error,
          Global => in all;
```

111/2 {*AI95-00302-03*} Equivalent to Element (Right) < Left.

```
{AI12-0112-1} procedure Reverse_Iterate                                    112/5
  (Container : in Set;
   Process   : not null access procedure (Position : in Cursor))
   with Allows_Exit;
```

{*AI95-00302-03*} {*AI05-0212-1*} Iterates over the elements in Container as per procedure Iterate, with the difference that the elements are traversed in predecessor order, starting with the last element. 113/3

```
{AI12-0112-1} {AI12-0266-1} function Iterate (Container : in Set)          113.1/5
   return Set_Iterator_Interfaces.Parallel_Reversible_Iterator'Class
   with Post => Tampering_With_Cursors_Prohibited (Container);
```

{*AI05-0212-1*} {*AI05-0265-1*} {*AI05-0269-1*} {*AI12-0266-1*} Iterate returns an iterator object (see 5.5.1) that will generate a value for a loop parameter (see 5.5.2) designating each element in Container, starting with the first element and moving the cursor according to the successor relation when used as a forward iterator, and starting with the last element and moving the cursor according to the predecessor relation when used as a reverse iterator, and processing all nodes concurrently when used as a parallel iterator. Tampering with the cursors of Container is prohibited while the iterator object exists (in particular, in the sequence_of_statements of the loop_statement whose iterator_specification denotes this object). The iterator object needs finalization. 113.2/5

```
function Iterate (Container : in Set; Start : in Cursor)                  113.3/5
   return Set_Iterator_Interfaces.Reversible_Iterator'Class
   with Pre  => (Start /= No_Element
                    or else raise Constraint_Error) and then
                (Has_Element (Container, Start)
                    or else raise Program_Error),
        Post => Tampering_With_Cursors_Prohibited (Container);
```

{*AI05-0262-1*} {*AI05-0265-1*} {*AI05-0269-1*} {*AI12-0112-1*} Iterate returns a reversible iterator object (see 5.5.1) that will generate a value for a loop parameter (see 5.5.2) designating each element in Container, starting with the element designated by Start and moving the cursor according to the successor relation when used as a forward iterator, or moving the cursor according to the predecessor relation when used as a reverse iterator. Tampering with the cursors of Container is prohibited while the iterator object exists (in particular, in the sequence_of_statements of the loop_statement whose iterator_specification denotes this object). The iterator object needs finalization. 113.4/5

Discussion: Exits are allowed from the loops created using the iterator objects. In particular, to stop the iteration at a particular cursor, just add 113.a/3

```
exit when Cur = Stop;                                                      113.b/3
```

in the body of the loop (assuming that `Cur` is the loop parameter and `Stop` is the cursor that you want to stop at). 113.c/3

{*AI95-00302-03*} For any two elements *E1* and *E2*, the boolean values (*E1* < *E2*) and (Key(*E1*) < Key(*E2*)) are expected to be equal. If the actuals for Key or Generic_Keys."<" behave in some other manner, the behavior of this package is unspecified. Which subprograms of this package call Key and Generic_Keys."<", and how many times the functions are called, is unspecified. 114/2

{*AI95-00302-03*} In addition to the semantics described in A.18.7, the subprograms in package Generic_Keys named Floor and Ceiling, are equivalent to the corresponding subprograms in the parent package, with the difference that the Key subprogram parameter is compared to elements in the container using the Key and "<" generic formal functions. The function named Equivalent_Keys in package Generic_Keys returns True if both Left < Right and Right < Left return False using the generic formal "<" operator, and returns True otherwise. 115/2

Implementation Advice

116/2 {*AI95-00302-03*} If *N* is the length of a set, then the worst-case time complexity of the Insert, Include, Replace, Delete, Exclude, and Find operations that take an element parameter should be *O*((log *N*)**2) or better. The worst-case time complexity of the subprograms that take a cursor parameter should be *O*(1).

116.a/2 **Implementation Advice:** The worst-case time complexity of the Insert, Include, Replace, Delete, Exclude, and Find operations of Containers.Ordered_Sets that take an element parameter should be *O*((log *N*)**2). The worst-case time complexity of the subprograms of Containers.Ordered_Sets that take a cursor parameter should be *O*(1).

116.b/2 **Implementation Note:** {*AI95-00302-03*} See A.18.6, "The Generic Package Containers.Ordered_Maps" for implementation notes regarding some of the operations of this package.

Extensions to Ada 95

116.c/2 {*AI95-00302-03*} The generic package Containers.Ordered_Sets is new.

Incompatibilities With Ada 2005

116.d/3 {*AI05-0001-1*} Subprograms Assign and Copy are added to Containers.Ordered_Sets. If an instance of Containers.Ordered_Sets is referenced in a use_clause, and an entity *E* with the same defining_identifier as a new entity in Containers.Ordered_Sets is defined in a package that is also referenced in a use_clause, the entity *E* may no longer be use-visible, resulting in errors. This should be rare and is easily fixed if it does occur.

Extensions to Ada 2005

116.e/3 {*AI05-0212-1*} Added iterator and indexing support to make ordered set containers more convenient to use.

Wording Changes from Ada 2005

116.f/3 {*AI05-0044-1*} **Correction:** Added wording to require the formal function be such that equal elements are also equivalent.

116.g/3 {*AI05-0044-1*} **Correction:** Redefined "<" actuals to require a strict weak ordering; the old definition allowed indeterminant comparisons that would not have worked in a container.

116.h/3 {*AI05-0084-1*} **Correction:** Added a pragma Remote_Types so that containers can be used in distributed programs.

Incompatibilities With Ada 2012

116.i/5 {*AI12-0111-1*} {*AI12-0112-1*} {*AI12-0339-1*} A number of new subprograms, types, and even a nested package were added to Containers.Ordered_Sets to better support contracts and stable views. Therefore, a use clause conflict is possible; see the introduction of Annex A for more on this topic.

Extensions to Ada 2012

116.j/5 {*AI12-0212-1*} Sets now support positional container aggregates, so aggregate syntax can be used to create Sets.

116.k/5 {*AI12-0266-1*} The iterator for the entire container now can return a parallel iterator which can be used to process the container in parallel.

Wording Changes from Ada 2012

116.l/5 {*AI12-0112-1*} Added contracts to this container. This includes describing some of the semantics with pre- and postconditions, rather than English text. Note that the preconditions can be Suppressed (see 11.5).

A.18.10 The Generic Package Containers.Multiway_Trees

1/3 {*AI05-0136-1*} The language-defined generic package Containers.Multiway_Trees provides private types Tree and Cursor, and a set of operations for each type. A multiway tree container is well-suited to represent nested structures.

1.a/3 **Discussion:** {*AI05-0136-1*} This tree just provides a basic structure, and make no promises about balancing or other automatic organization. In this sense, it is different than the indexed (Map, Set) forms. Rather, it provides a building block on which to construct more complex and more specialized tree containers.

2/4 {*AI05-0136-1*} {*AI12-0078-1*} {*AI12-0159-1*} A multiway tree container object manages a tree of *nodes*, consisting of a *root node* and a set of *internal nodes*; each internal node contains an element and pointers

to the parent, first child, last child, next (successor) sibling, and previous (predecessor) sibling internal nodes. A cursor designates a particular node within a tree (and by extension the element contained in that node, if any). A cursor keeps designating the same node (and element) as long as the node is part of the container, even if the node is moved within the container.

{*AI05-0136-1*} {*AI05-0269-1*} {*AI12-0078-1*} A *subtree* is a particular node (which *roots the subtree*) and all of its child nodes (including all of the children of the child nodes, recursively). The root node is always present and has neither an associated element value nor any parent node; it has pointers to its first child and its last child, if any. The root node provides a place to add nodes to an otherwise empty tree and represents the base of the tree. 3/4

{*AI05-0136-1*} {*AI05-0269-1*} A node that has no children is called a *leaf node*. The *ancestors* of a node are the node itself, its parent node, the parent of the parent node, and so on until a node with no parent is reached. Similarly, the *descendants* of a node are the node itself, its child nodes, the children of each child node, and so on. 4/3

{*AI05-0136-1*} {*AI05-0262-1*} {*AI05-0269-1*} The nodes of a subtree can be visited in several different orders. For a *depth-first order*, after visiting a node, the nodes of its child list are each visited in depth-first order, with each child node visited in natural order (first child to last child). 5/3

Ramification: For the depth-first order, when each child node is visited, the child list of the child node is visited before the next sibling of the child node is visited. 5.a/3

Static Semantics

{*AI05-0136-1*} The generic library package Containers.Multiway_Trees has the following declaration: 6/3

```
{AI05-0136-1} {AI05-0212-1} {AI12-0112-1} with Ada.Iterator_Interfaces;                    7/5
generic
   type Element_Type is private;
   with function "=" (Left, Right : Element_Type) return Boolean is <>;
package Ada.Containers.Multiway_Trees
   with Preelaborate, Remote_Types,
        Nonblocking, Global => in out synchronized is
```

Discussion: {*AI12-0112-1*} For discussion on the reasons and meaning of the specifications of the Global and Nonblocking aspects in this generic package, see the notes on the equivalent operations in the specification of the Containers.Vectors package (see A.18.2). 7.a/5

           Nonblocking, Global => null, Use_Formal => null;
```

22/5
```
{AI12-0112-1}    function Root (Container : Tree) return Cursor
      with Nonblocking, Global => null, Use_Formal => null,
           Post => Root'Result /= No_Element and then
                   not Has_Element (Container, Root'Result);
```

22.1/5
```
{AI12-0112-1}    function Meaningful_For (Container : Tree; Position : Cursor)
      return Boolean is
      (Position = No_Element or else
       Is_Root (Container, Position) or else
       Has_Element (Container, Position))
      with Nonblocking, Global => null, Use_Formal => null;
```

Reason: {*AI12-0112-1*} When this function is true, the Position can be meaningfully used with operations for Container. We define this because many operations allow the root (which does not have an element, so Has_Element returns False), so many preconditions get unwieldy. We allow No_Element as it is allowed by many queries, and for existing routines, it raises a different exception (Constraint_Error rather than Program_Error) than a cursor for the wrong container does. 22.a/5

23/5

{*AI05-0136-1*} The actual function for the generic formal function "=" on Element_Type values is expected to define a reflexive and symmetric relationship and return the same result value each time it is called with a particular pair of values. If it behaves in some other manner, the functions Find, Reverse_Find, Equal_Subtree, and "=" on tree values return an unspecified value. The exact arguments and number of calls of this generic formal function by the functions Find, Reverse_Find, Equal_Subtree, and "=" on tree values are unspecified. 72/3

{*AI05-0136-1*} The type Tree is used to represent trees. The type Tree needs finalization (see 7.6). 73/3

{*AI05-0136-1*} {*AI05-0248-1*} Empty_Tree represents the empty Tree object. It contains only the root node (Node_Count (Empty_Tree) returns 1). If an object of type Tree is not otherwise initialized, it is initialized to the same value as Empty_Tree. 74/3

{*AI05-0136-1*} No_Element represents a cursor that designates no element. If an object of type Cursor is not otherwise initialized, it is initialized to the same value as No_Element. 75/3

{*AI05-0136-1*} {*AI12-0434-1*} The primitive "=" operator for type Cursor returns True if both cursors are No_Element, or designate the same element in the same container. 76/5

To be honest: {*AI12-0434-1*} “The primitive "=" operator” is the one with two parameters of type Cursor which returns Boolean. We're not talking about some other (hidden) primitive function named "=". 76.a/5

{*AI05-0136-1*} Execution of the default implementation of the Input, Output, Read, or Write attribute of type Cursor raises Program_Error. 77/3

{*AI05-0136-1*} {*AI05-0248-1*} {*AI05-0262-1*} {*AI12-0437-1*} Tree'Write for a Tree object *T* writes Node_Count(*T*) - 1 elements of the tree to the stream. It may also write additional information about the tree. 78/5

{*AI05-0136-1*} {*AI05-0248-1*} {*AI05-0262-1*} Tree'Read reads the representation of a tree from the stream, and assigns to *Item* a tree with the same elements and structure as was written by Tree'Write. 79/3

Ramification: Streaming more elements than the container holds is wrong. For implementation implications of this rule, see the Implementation Note in A.18.2. 79.a/3

{*AI05-0136-1*} {*AI12-0111-1*} {*AI12-0112-1*} [Some operations check for “tampering with cursors” of a container because they depend on the set of elements of the container remaining constant, and others check for “tampering with elements” of a container because they depend on elements of the container not being replaced.] When tampering with cursors is *prohibited* for a particular tree object *T*, Program_Error is propagated by the finalization of *T*[, as well as by a call that passes *T* to certain of the operations of this package, as indicated by the precondition of such an operation]. Similarly, when tampering with elements is *prohibited* for *T*, Program_Error is propagated by a call that passes *T* to certain of the other operations of this package, as indicated by the precondition of such an operation. 80/5

Paragraphs 81 through 90 are removed as preconditions now describe these rules.

Ramification: We don't need to explicitly mention assignment_statement, because that finalizes the target object as part of the operation, and finalization of an object is already defined as tampering with cursors. 85.a.1/3

91/5 {*AI12-0112-1*}
```
function Has_Element (Position : Cursor) return Boolean
   with Nonblocking, Global => in all, Use_Formal => null;
```

92/3 Returns True if Position designates an element, and returns False otherwise. [In particular, Has_Element returns False if the cursor designates a root node or equals No_Element.]

92.a/3 **To be honest:** {*AI05-0005-1*} {*AI05-0136-1*} This function might not detect cursors that designate deleted elements; such cursors are invalid (see below) and the result of calling Has_Element with an invalid cursor is unspecified (but not erroneous).

92.1/5
```
function Has_Element (Container : Tree; Position : Cursor)
   return Boolean
   with Nonblocking, Global => null, Use_Formal => null;
```

92.2/5 {*AI12-0112-1*} Returns True if Position designates an element in Container, and returns False otherwise. [In particular, Has_Element returns False if the cursor designates a root node or equals No_Element.]

93/3
```
function Equal_Subtree (Left_Position : Cursor;
                        Right_Position: Cursor) return Boolean;
```

94/3 {*AI05-0136-1*} {*AI05-0248-1*} {*AI05-0262-1*} {*AI05-0264-1*} If Left_Position or Right_Position equals No_Element, propagates Constraint_Error. If the number of child nodes of the element designated by Left_Position is different from the number of child nodes of the element designated by Right_Position, the function returns False. If Left_Position designates a root node and Right_Position does not, the function returns False. If Right_Position designates a root node and Left_Position does not, the function returns False. Unless both cursors designate a root node, the elements are compared using the generic formal equality operator. If the result of the element comparison is False, the function returns False. Otherwise, it calls Equal_Subtree on a cursor designating each child element of the element designated by Left_Position and a cursor designating the corresponding child element of the element designated by Right_Position. If any such call returns False, the function returns False; otherwise, it returns True. Any exception raised during the evaluation of element equality is propagated.

94.a/3 **Ramification:** Left_Position and Right_Position do not need to be from the same tree.

94.b/3 **Implementation Note:** This wording describes the canonical semantics. However, the order and number of calls on the formal equality function is unspecified for all of the operations that use it in this package, so an implementation can call it as many or as few times as it needs to get the correct answer. Similarly, a global rule (see the introduction of Annex A) says that language-defined routines are not affected by overriding of other language-defined routines. This means that no reasonable program can tell how many times Equal_Subtree is called, and thus an implementation can call it as many or as few times as it needs to get the correct answer. Specifically, there is no requirement to call the formal equality or Equal_Subtree additional times once the answer has been determined.

95/3
```
function "=" (Left, Right : Tree) return Boolean;
```

96/3 {*AI05-0136-1*} {*AI05-0262-1*} If Left and Right denote the same tree object, then the function returns True. Otherwise, it calls Equal_Subtree with cursors designating the root nodes of Left and Right; the result is returned. Any exception raised during the evaluation of Equal_Subtree is propagated.

96.a/3 **Implementation Note:** Similar considerations apply here as apply to Equal_Subtree. The actual number of calls performed is unspecified.

96.1/5
```
function Tampering_With_Cursors_Prohibited
   (Container : Tree) return Boolean
   with Nonblocking, Global => null, Use_Formal => null;
```

96.2/5 {*AI12-0112-1*} Returns True if tampering with cursors or tampering with elements is currently prohibited for Container, and returns False otherwise.

96.b/5 **Reason:** {*AI12-0112-1*} Prohibiting tampering with elements also needs to prohibit tampering with cursors, as deleting an element is similar to replacing it.

Implementation Note: {*AI12-0112-1*} Various contracts elsewhere in this specification require that this function be implemented with synchronized data. Moreover, it is possible for tampering to be prohibited by multiple operations (sequentially or in parallel). Therefore, tampering needs to be implemented with an atomic or protected counter. The counter is initialized to zero, and is incremented when tampering is prohibited, and decremented when leaving an area that prohibited tampering. Function Tampering_With_Cursors_Prohibited returns True if the counter is nonzero. (Note that any case where the result is not well-defined for one task is incorrect use of shared variables and would be erroneous by the rules of 9.10, so no special protection is needed to read the counter.) 96.c/5

```
function Tampering_With_Elements_Prohibited                                    96.3/5
   (Container : Tree) return Boolean
   with Nonblocking, Global => null, Use_Formal => null;
```

{*AI12-0112-1*} Always returns False[, regardless of whether tampering with elements is prohibited]. 96.4/5

Reason: {*AI12-0111-1*} A definite element cannot change size, so we allow operations that tamper with elements even when tampering with elements is prohibited. That's not true for the indefinite containers, which is why this kind of tampering exists. 96.d/5

```
function Is_Empty (Container : Tree) return Boolean                            96.5/5
   with Nonblocking, Global => null, Use_Formal => null,
        Post => Is_Empty'Result = (Node_Count (Container) = 1);
```

{*AI05-0136-1*} {*AI12-0112-1*} Returns True if Container is empty. 96.6/5

Ramification: An empty tree contains just the root node. 96.e/5

```
{AI12-0112-1} function Node_Count (Container : Tree) return Count_Type         97/5
   with Nonblocking, Global => null, Use_Formal => null;
```

{*AI05-0136-1*} Node_Count returns the number of nodes in Container. 98/3

Ramification: Since all tree objects have a root node, this can never return a value of 0. Node_Count (Some_Tree) should always equal Subtree_Node_Count (Root (Some_Tree)). 98.a/3

```
{AI12-0112-1} function Subtree_Node_Count (Position : Cursor) return Count_Type  99/5
   with Nonblocking, Global => in all, Use_Formal => null);
```

{*AI05-0136-1*} {*AI05-0248-1*} If Position is No_Element, Subtree_Node_Count returns 0; otherwise, Subtree_Node_Count returns the number of nodes in the subtree that is rooted by Position. 100/3

```
function Subtree_Node_Count (Container : Tree; Position : Cursor)              101/5
   return Count_Type
   with Pre => Meaningful_For (Container, Position)
                  or else raise Program_Error,
        Nonblocking, Global => null, Use_Formal => null;
```

{*AI05-0136-1*} {*AI12-0112-1*} If Position is No_Element, Subtree_Node_Count returns 0; otherwise, Subtree_Node_Count returns the number of nodes in the subtree of Container that is rooted by Position. 102/5

This paragraph was deleted.{*AI12-0112-1*} 102.a/5

Reason: {*AI12-0112-1*} We raise Program_Error if Position belongs to some other container because we have promised to read only the container passed to this function. Determining the answer requires reading the container that Position belongs to, which we've promised not to do if it is not Container. We don't make this check for functions like Has_Element and Is_Root which do not require reading another container to determine the answer, but we do make it for most functions. 102.b/5

```
{AI12-0112-1} function Depth (Position : Cursor) return Count_Type             103/5
   with Nonblocking, Global => in all, Use_Formal => null;
```

{*AI05-0136-1*} {*AI05-0248-1*} If Position equals No_Element, Depth returns 0; otherwise, Depth returns the number of ancestor nodes of the node designated by Position (including the node itself). 104/3

Ramification: Depth (Root (Some_Tree)) = 1. 104.a/3

104.1/5
```
function Depth (Container : Tree; Position : Cursor)
   return Count_Type
   with Pre => Meaningful_For (Container, Position)
                  or else raise Program_Error,
        Nonblocking, Global => null, Use_Formal => null;
```

104.2/5 {*AI12-0112-1*} If Position equals No_Element, Depth returns 0; otherwise, Depth returns the number of ancestor nodes of the node of Container designated by Position (including the node itself).

105/5
```
{AI12-0112-1} function Is_Root (Position : Cursor) return Boolean
   with Nonblocking, Global => in all, Use_Formal => null;
```

106/3 {*AI05-0136-1*} {*AI05-0248-1*} Is_Root returns True if the Position designates the root node of some tree; and returns False otherwise.

106.1/5
```
function Is_Root (Container : Tree; Position : Cursor)
   return Boolean
   with Nonblocking, Global => null, Use_Formal => null;
```

106.2/5 {*AI12-0112-1*} Is_Root returns True if the Position designates the root node of Container; and returns False otherwise.

106.a/5 **Ramification:** The two parameter Is_Root returns False even if Position is the root of some other tree than Container.

107/5
```
{AI12-0112-1} function Is_Leaf (Position : Cursor) return Boolean
   with Nonblocking, Global => in all, Use_Formal => null;
```

108/3 {*AI05-0136-1*} Is_Leaf returns True if Position designates a node that does not have any child nodes; and returns False otherwise.

108.a/3 **Ramification:** Is_Leaf returns False if passed No_Element, since No_Element does not designate a node. Is_Leaf can be passed a cursor that designates the root node; Is_Leaf will return True if passed the root node of an empty tree.

108.1/5
```
function Is_Leaf (Container : Tree; Position : Cursor)
   return Boolean
   with Pre => Meaningful_For (Container, Position)
                  or else raise Program_Error,
        Nonblocking, Global => null, Use_Formal => null;
```

108.2/5 {*AI12-0112-1*} Is_Leaf returns True if Position designates a node in Container that does not have any child nodes; and returns False otherwise.

108.3/5
```
function Is_Ancestor_Of (Container : Tree;
                         Parent   : Cursor;
                         Position : Cursor) return Boolean
   with Pre => (Meaningful_For (Container, Position)
                  or else raise Program_Error) and then
               (Meaningful_For (Container, Parent)
                  or else raise Program_Error),
        Nonblocking, Global => null, Use_Formal => null;
```

108.4/5 {*AI12-0112-1*} Is_Ancestor_Of returns True if Parent designates an ancestor node of Position (including Position itself), and returns False otherwise.

109/5
```
{AI12-0112-1} function Root (Container : Tree) return Cursor
   with Nonblocking, Global => null, Use_Formal => null,
        Post => Root'Result /= No_Element and then
                not Has_Element (Container, Root'Result);
```

110/3 {*AI05-0136-1*} Root returns a cursor that designates the root node of Container.

110.a/3 **Ramification:** There is always a root node, even in an empty container, so this function never returns No_Element.

```
{AI12-0112-1} procedure Clear (Container : in out Tree)                                    111/5
   with Pre  => not Tampering_With_Cursors_Prohibited (Container)
                    or else raise Program_Error,
        Post => Node_Count (Container) = 1;
```

{*AI05-0136-1*} Removes all the elements from Container. 112/3

Ramification: The root node is not removed; all trees have a root node. 112.a/3

```
function Element (Position : Cursor) return Element_Type                                   113/5
   with Pre => (Position /= No_Element or else
                   raise Constraint_Error) and then
               (Has_Element (Position) or else raise Program_Error),
        Nonblocking, Global => in all, Use_Formal => Element_Type;
```

{*AI05-0136-1*} {*AI12-0112-1*} Element returns the element designated by Position. 114/5

Ramification: The root node does not contain an element, so that value cannot be read or written. 114.a/3

```
function Element (Container : Tree;                                                        114.1/5
                  Position  : Cursor) return Element_Type
   with Pre => (Position /= No_Element
                   or else raise Constraint_Error) and then
               (Has_Element (Container, Position)
                   or else raise Program_Error),
        Nonblocking, Global => null, Use_Formal => Element_Type;
```

{*AI12-0112-1*} Element returns the element designated by Position in Container. 114.2/5

```
procedure Replace_Element (Container : in out Tree;                                        115/5
                           Position  : in     Cursor;
                           New_item  : in     Element_Type)
   with Pre  => (not Tampering_With_Elements_Prohibited (Container)
                   or else raise Program_Error) and then
                (Position /= No_Element
                   or else raise Constraint_Error) and then
                (Has_Element (Container, Position)
                   or else raise Program_Error);
```

{*AI05-0136-1*} {*AI05-0264-1*} {*AI12-0112-1*} {*AI12-0196-1*} Replace_Element assigns the value New_Item to the element designated by Position. For the purposes of determining whether the parameters overlap in a call to Replace_Element, the Container parameter is not considered to overlap with any object [(including itself)]. 116/5

```
procedure Query_Element                                                                    117/5
  (Position : in Cursor;
   Process  : not null access procedure (Element : in Element_Type))
   with Pre  => (Position /= No_Element
                   or else raise Constraint_Error) and then
                (Has_Element (Position)
                   or else raise Program_Error),
     Global => in all;
```

{*AI05-0136-1*} {*AI05-0265-1*} {*AI12-0112-1*} Query_Element calls Process.**all** with the element designated by Position as the argument. Tampering with the elements of the tree that contains the element designated by Position is prohibited during the execution of the call on Process.**all**. Any exception raised by Process.**all** is propagated. 118/5

```
procedure Query_Element                                                                    118.1/5
  (Container : in Tree;
   Position  : in Cursor;
   Process   : not null access procedure (Element : in Element_Type))
   with Pre  => (Position /= No_Element
                   or else raise Constraint_Error) and then
                (Has_Element (Container, Position)
                   or else raise Program_Error);
```

118.2/5 {*AI12-0112-1*} Query_Element calls Process.**all** with the element designated by Position as the argument. Tampering with the elements of Container is prohibited during the execution of the call on Process.**all**. Any exception raised by Process.**all** is propagated.

119/5
```
procedure Update_Element
   (Container : in out Tree;
    Position  : in     Cursor;
    Process   : not null access procedure
                     (Element : in out Element_Type))
    with Pre  => (Position /= No_Element
                     or else raise Constraint_Error) and then
                  (Has_Element (Container, Position)
                     or else raise Program_Error);
```

120/5 {*AI05-0136-1*} {*AI05-0264-1*} {*AI05-0265-1*} {*AI12-0112-1*} Update_Element calls Process.**all** with the element designated by Position as the argument. Tampering with the elements of Container is prohibited during the execution of the call on Process.**all**. Any exception raised by Process.**all** is propagated.

121/3 If Element_Type is unconstrained and definite, then the actual Element parameter of Process.**all** shall be unconstrained.

121.a/3 **Ramification:** This means that the elements cannot be directly allocated from the heap; it must be possible to change the discriminants of the element in place.

122/5
```
{AI12-0112-1} type Constant_Reference_Type
      (Element : not null access constant Element_Type) is private
   with Implicit_Dereference => Element,
        Nonblocking, Global => in out synchronized,
        Default_Initial_Condition => (raise Program_Error);
```

123/5
```
{AI12-0112-1} type Reference_Type (Element : not null access Element_Type) is
private
   with Implicit_Dereference => Element,
        Nonblocking, Global => in out synchronized,
        Default_Initial_Condition => (raise Program_Error);
```

124/3 {*AI05-0212-1*} The types Constant_Reference_Type and Reference_Type need finalization.

125/5 *This paragraph was deleted.*{*AI12-0112-1*}

125.a/3 **Reason:** It is expected that Reference_Type (and Constant_Reference_Type) will be a controlled type, for which finalization will have some action to terminate the tampering check for the associated container. If the object is created by default, however, there is no associated container. Since this is useless, and supporting this case would take extra work, we define it to raise an exception.

126/5
```
{AI12-0112-1} function Constant_Reference (Container : aliased in Tree;
                                Position  : in Cursor)
   return Constant_Reference_Type
   with Pre  => (Position /= No_Element
                    or else raise Constraint_Error) and then
                 (Has_Element (Container, Position)
                    or else raise Program_Error),
        Post   => Tampering_With_Cursors_Prohibited (Container),
        Nonblocking, Global => null, Use_Formal => null;
```

127/3 {*AI05-0212-1*} {*AI05-0269-1*} This function (combined with the Constant_Indexing and Implicit_Dereference aspects) provides a convenient way to gain read access to an individual element of a tree given a cursor.

128/5 {*AI05-0212-1*} {*AI05-0265-1*} {*AI12-0112-1*} Constant_Reference returns an object whose discriminant is an access value that designates the element designated by Position. Tampering with the elements of Container is prohibited while the object returned by Constant_Reference exists and has not been finalized.

```
{AI12-0112-1} function Reference (Container : aliased in out Tree;                    129/5
                                  Position  : in Cursor)
   return Reference_Type
   with Pre  => (Position /= No_Element
                    or else raise Constraint_Error) and then
                 (Has_Element (Container, Position)
                    or else raise Program_Error),
        Post   => Tampering_With_Cursors_Prohibited (Container),
        Nonblocking, Global => null, Use_Formal => null;
```

{*AI05-0212-1*} {*AI05-0269-1*} This function (combined with the Variable_Indexing and Implicit_Dereference aspects) provides a convenient way to gain read and write access to an individual element of a tree given a cursor. 130/3

{*AI05-0212-1*} {*AI05-0265-1*} {*AI12-0112-1*} Reference returns an object whose discriminant is an access value that designates the element designated by Position. Tampering with the elements of Container is prohibited while the object returned by Reference exists and has not been finalized. 131/5

```
{AI12-0112-1} procedure Assign (Target : in out Tree; Source : in Tree)               132/5
   with Pre  => not Tampering_With_Cursors_Prohibited (Target)
                    or else raise Program_Error,
        Post => Node_Count (Source) = Node_Count (Target);
```

{*AI05-0136-1*} {*AI05-0248-1*} If Target denotes the same object as Source, the operation has no effect. Otherwise, the elements of Source are copied to Target as for an assignment_statement assigning Source to Target. 133/3

Ramification: Each element in Target has a parent element that corresponds to the parent element of the Source element, and has child elements that correspond to the child elements of the Source element. 133.a/3

Discussion: {*AI05-0005-1*} This routine exists for compatibility with the bounded tree container. For an unbounded tree, `Assign(A, B)` and `A := B` behave identically. For a bounded tree, := will raise an exception if the container capacities are different, while Assign will not raise an exception if there is enough room in the target. 133.b/3

```
{AI12-0112-1} function Copy (Source : Tree) return Tree                               134/5
   with Post =>
           Node_Count (Copy'Result) = Node_Count (Source) and then
           not Tampering_With_Elements_Prohibited (Copy'Result) and then
           not Tampering_With_Cursors_Prohibited (Copy'Result);
```

{*AI05-0136-1*} Returns a tree with the same structure as Source and whose elements are initialized from the corresponding elements of Source. 135/3

```
{AI12-0112-1} procedure Move (Target : in out Tree;                                   136/5
                              Source : in out Tree)
   with Pre  => (not Tampering_With_Cursors_Prohibited (Target)
                    or else raise Program_Error) and then
                 (not Tampering_With_Cursors_Prohibited (Source)
                    or else raise Program_Error),
        Post => (if not Target'Has_Same_Storage (Source) then
                    Node_Count (Target) = Node_Count (Source'Old) and then
                    Node_Count (Source) = 1);
```

{*AI05-0136-1*} {*AI05-0248-1*} If Target denotes the same object as Source, then the operation has no effect. Otherwise, Move first calls Clear (Target). Then, the nodes other than the root node in Source are moved to Target (in the same positions). After Move completes, Node_Count (Target) is the number of nodes originally in Source, and Node_Count (Source) is 1. 137/3

138/5
```
procedure Delete_Leaf (Container : in out Tree;
                       Position  : in out Cursor)
   with Pre  => (not Tampering_With_Cursors_Prohibited (Container)
                    or else raise Program_Error) and then
                 (Position /= No_Element
                    or else raise Constraint_Error) and then
                 (Has_Element (Container, Position)
                    or else raise Program_Error) and then
                 (Is_Leaf (Container, Position)
                    or else raise Constraint_Error),
        Post =>
           Node_Count (Container)'Old = Node_Count (Container) + 1 and then
           Position = No_Element;
```

139/5 {*AI05-0136-1*} {*AI05-0248-1*} {*AI12-0112-1*} Delete_Leaf removes (from Container) the element designated by Position, and Position is set to No_Element.

139.a/3 **Ramification:** The check on Position checks that the cursor does not belong to some other Container. This check implies that a reference to the container is included in the cursor value. This wording is not meant to require detection of dangling cursors; such cursors are defined to be invalid, which means that execution is erroneous, and any result is allowed (including not raising an exception).

139.b/3 The root node cannot be deleted.

140/5
```
procedure Delete_Subtree (Container : in out Tree;
                          Position  : in out Cursor)
   with Pre  => (not Tampering_With_Cursors_Prohibited (Container)
                    or else raise Program_Error) and then
                 (Position /= No_Element
                    or else raise Constraint_Error) and then
                 (Has_Element (Container, Position)
                    or else raise Program_Error),
        Post => Node_Count (Container)'Old = Node_Count (Container) +
                    Subtree_Node_Count (Container, Position)'Old and then
                 Position = No_Element;
```

141/5 {*AI05-0136-1*} {*AI05-0264-1*} {*AI05-0269-1*} {*AI12-0112-1*} Delete_Subtree removes (from Container) the subtree designated by Position (that is, all descendants of the node designated by Position including the node itself), and Position is set to No_Element.

141.a/3 **Ramification:** The root node cannot be deleted. To delete the entire contents of the tree, call Clear(Container).

142/5
```
procedure Swap (Container : in out Tree;
                I, J      : in     Cursor)
   with Pre  => (not Tampering_With_Cursors_Prohibited (Container)
                    or else raise Program_Error) and then
                 (I /= No_Element or else Constraint_Error) and then
                 (J /= No_Element or else Constraint_Error) and then
                 (Has_Element (Container, I)
                    or else raise Program_Error) and then
                 (Has_Element (Container, J)
                    or else raise Program_Error);
```

143/5 {*AI05-0136-1*} {*AI12-0112-1*} Swap exchanges the values of the elements designated by I and J.

143.a/3 **Ramification:** After a call to Swap, I designates the element value previously designated by J, and J designates the element value previously designated by I. The position of the elements do not change; for instance, the parent node and the first child node of I are unchanged by the operation.

143.b/3 The root nodes do not contain element values, so they cannot be swapped.

143.c/3 **To be honest:** The implementation is not required to actually copy the elements if it can do the swap some other way. But it is allowed to copy the elements if needed.

```
{AI12-0112-1} function Find (Container : Tree;                                    144/5
                             Item      : Element_Type)
   return Cursor
   with Post => (if Find'Result /= No_Element
                 then Has_Element (Container, Find'Result));
```

{*AI05-0136-1*} {*AI05-0262-1*} Find searches the elements of Container for an element equal to Item (using the generic formal equality operator). The search starts at the root node. The search traverses the tree in a depth-first order. If no equal element is found, then Find returns No_Element. Otherwise, it returns a cursor designating the first equal element encountered. 145/3

```
function Find_In_Subtree (Position : Cursor;                                      146/5
                          Item     : Element_Type)
   return Cursor
   with Pre  => Position /= No_Element or else raise Constraint_Error,
        Post => (if Find_In_Subtree'Result = No_Element
                 then Has_Element (Find_In_Subtree'Result)),
        Global => in all;
```

{*AI05-0136-1*} {*AI05-0248-1*} {*AI05-0262-1*} {*AI12-0112-1*} Find_In_Subtree searches the subtree rooted by Position for an element equal to Item (using the generic formal equality operator). The search starts at the element designated by Position. The search traverses the subtree in a depth-first order. If no equal element is found, then Find returns No_Element. Otherwise, it returns a cursor designating the first equal element encountered. 147/5

Ramification: Find_In_Subtree does not check any siblings of the element designated by Position. The root node does not contain an element, and therefore it can never be returned, but it can be explicitly passed to Position. 147.a/3

```
{AI12-0112-1} function Find_In_Subtree (Container : Tree;                         147.1/5
                          Position  : Cursor;
                          Item      : Element_Type)
   return Cursor
   with Pre  => (Position /= No_Element
                    or else raise Constraint_Error) and then
                (Meaningful_For (Container, Position)
                    or else raise Program_Error),
        Post => (if Find_In_Subtree'Result = No_Element
                 then Has_Element (Container, Find_In_Subtree'Result));
```

{*AI12-0112-1*} Find_In_Subtree searches the subtree of Container rooted by Position for an element equal to Item (using the generic formal equality operator). The search starts at the element designated by Position. The search traverses the subtree in a depth-first order. If no equal element is found, then Find returns No_Element. Otherwise, it returns a cursor designating the first equal element encountered. 147.2/5

```
function Ancestor_Find (Position : Cursor;                                        148/5
                        Item     : Element_Type)
   return Cursor
   with Pre  => Position /= No_Element or else raise Constraint_Error,
        Post => (if Ancestor_Find'Result = No_Element
                 then Has_Element (Container, Ancestor_Find'Result)),
        Global => in all;
```

{*AI05-0136-1*} {*AI05-0248-1*} {*AI12-0112-1*} Ancestor_Find searches for an element equal to Item (using the generic formal equality operator). The search starts at the node designated by Position, and checks each ancestor proceeding toward the root of the subtree. If no equal element is found, then Ancestor_Find returns No_Element. Otherwise, it returns a cursor designating the first equal element encountered. 149/5

Ramification: {*AI05-0248-1*} No_Element is returned if Position is the root node. 149.a/3

149.1/5
```
{AI12-0112-1} function Ancestor_Find (Container : Tree;
                                      Position  : Cursor;
                                      Item      : Element_Type)
   return Cursor
   with Pre  => (Position /= No_Element
                    or else raise Constraint_Error) and then
                (Meaningful_For (Container, Position)
                    or else raise Program_Error),
        Post => (if Ancestor_Find'Result = No_Element
                 then Has_Element (Container, Ancestor_Find'Result));
```

149.2/5 {*AI12-0112-1*} Ancestor_Find searches for an element equal to Item (using the generic formal equality operator). The search starts at the node designated by Position in Container, and checks each ancestor proceeding toward the root of the subtree. If no equal element is found, then Ancestor_Find returns No_Element. Otherwise, it returns a cursor designating the first equal element encountered.

150/3
```
function Contains (Container : Tree;
                   Item      : Element_Type) return Boolean;
```

151/3 {*AI05-0136-1*} Equivalent to Find (Container, Item) /= No_Element.

152/5
```
{AI12-0112-1} procedure Iterate
  (Container : in Tree;
   Process   : not null access procedure (Position : in Cursor))
   with Allows_Exit;
```

153/4 {*AI05-0136-1*} {*AI05-0265-1*} {*AI12-0069-1*} Iterate calls Process.**all** with a cursor that designates each element in Container, starting from the root node and proceeding in a depth-first order. Tampering with the cursors of Container is prohibited during the execution of a call on Process.**all**. Any exception raised by Process.**all** is propagated.

153.a/3 **Ramification:** Process is not called with the root node, which does not have an associated element.

153.b/3 **Implementation Note:** The purpose of the tamper with cursors check is to prevent erroneous execution from the Position parameter of Process.**all** becoming invalid. This check takes place when the operations that tamper with the cursors of the container are called. The check cannot be made later (say in the body of Iterate), because that could cause the Position cursor to be invalid and potentially cause execution to become erroneous — defeating the purpose of the check.

153.c/3 See Iterate for vectors (A.18.2) for a suggested implementation of the check.

154/5
```
procedure Iterate_Subtree
  (Position  : in Cursor;
   Process   : not null access procedure (Position : in Cursor))
   with Allows_Exit,
        Pre  => Position /= No_Element or else raise Constraint_Error,
        Global => in all;
```

155/5 {*AI05-0136-1*} {*AI05-0265-1*} {*AI12-0069-1*} {*AI12-0112-1*} Iterate_Subtree calls Process.**all** with a cursor that designates each element in the subtree rooted by the node designated by Position, starting from the node designated by Position and proceeding in a depth-first order. Tampering with the cursors of the tree that contains the element designated by Position is prohibited during the execution of a call on Process.**all**. Any exception raised by Process.**all** is propagated.

155.a/3 **Ramification:** Position can be passed a cursor designating the root node; in that case, Process is not called with the root node, which does not have an associated element.

```
procedure Iterate_Subtree                                                    155.1/5
  (Container : in Tree;
   Position  : in Cursor;
   Process   : not null access procedure (Position : in Cursor))
   with Allows_Exit,
        Pre  => (Position /= No_Element
                   or else raise Constraint_Error) and then
                (Meaningful_For (Container, Position)
                   or else raise Program_Error);
```

{*AI12-0112-1*} Iterate_Subtree calls Process.**all** with a cursor that designates each element in the subtree rooted by the node designated by Position in Container, starting from the node designated by Position and proceeding in a depth-first order. Tampering with the cursors of the tree that contains the element designated by Position is prohibited during the execution of a call on Process.**all**. Any exception raised by Process.**all** is propagated. 155.2/5

```
{AI12-0112-1} function Iterate (Container : in Tree)                         156/5
   return Tree_Iterator_Interfaces.Parallel_Iterator'Class
   with Post => Tampering_With_Cursors_Prohibited (Container);
```

{*AI05-0212-1*} {*AI05-0265-1*} {*AI05-0269-1*} {*AI12-0069-1*} {*AI12-0266-1*} Iterate returns an iterator object (see 5.5.1) that will generate a value for a loop parameter (see 5.5.2) designating each element in Container, starting from the root node and proceeding in a depth-first order when used as a forward iterator, and processing all nodes concurrently when used as a parallel iterator. Tampering with the cursors of Container is prohibited while the iterator object exists (in particular, in the sequence_of_statements of the loop_statement whose iterator_specification denotes this object). The iterator object needs finalization. 157/5

Discussion: Exits are allowed from the loops created using the iterator objects. In particular, to stop the iteration at a particular cursor, just add 157.a/3

```
exit when Cur = Stop;                                                        157.b/3
```

in the body of the loop (assuming that `Cur` is the loop parameter and `Stop` is the cursor that you want to stop at). 157.c/3

```
function Iterate_Subtree (Position : in Cursor)                              158/5
   return Tree_Iterator_Interfaces.Parallel_Iterator'Class
   with Pre    => Position /= No_Element or else raise Constraint_Error,
        Global => in all;
```

{*AI05-0212-1*} {*AI05-0265-1*} {*AI05-0269-1*} {*AI12-0069-1*} {*AI12-0112-1*} {*AI12-0266-1*} Iterate_Subtree returns an iterator object (see 5.5.1) that will generate a value for a loop parameter (see 5.5.2) designating each element in the subtree rooted by the node designated by Position, starting from the node designated by Position and proceeding in a depth-first order when used as a forward iterator, and processing all nodes in the subtree concurrently when used as a parallel iterator. Tampering with the cursors of the container that contains the node designated by Position is prohibited while the iterator object exists (in particular, in the sequence_of_statements of the loop_statement whose iterator_specification denotes this object). The iterator object needs finalization. 159/5

```
function Iterate_Subtree (Container : in Tree; Position : in Cursor)         159.1/5
   return Tree_Iterator_Interfaces.Parallel_Iterator'Class
   with Pre  => (Position /= No_Element
                   or else raise Constraint_Error) and then
                (Meaningful_For (Container, Position)
                   or else raise Program_Error),
        Post => Tampering_With_Cursors_Prohibited (Container);
```

{*AI12-0112-1*} Iterate_Subtree returns an iterator object (see 5.5.1) that will generate a value for a loop parameter (see 5.5.2) designating each element in the subtree rooted by the node designated by Position in Container, starting from the node designated by Position and proceeding in a depth-first order when used as a forward iterator, and processing all nodes in the 159.2/5

subtree concurrently when used as a parallel iterator. Tampering with the cursors of the container that contains the node designated by Position is prohibited while the iterator object exists (in particular, in the sequence_of_statements of the loop_statement whose iterator_specification denotes this object). The iterator object needs finalization.

160/5
```
{AI12-0112-1} function Child_Count (Parent : Cursor) return Count_Type
   with Post => (if Parent = No_Element then Child_Count'Result = 0),
        Nonblocking, Global => in all, Use_Formal => null;
```

161/3 {*AI05-0136-1*} Child_Count returns the number of child nodes of the node designated by Parent.

161.1/5
```
function Child_Count (Container : Tree; Parent : Cursor)
   return Count_Type
   with Pre  => Meaningful_For (Container, Parent)
                   or else raise Program_Error,
        Post => (if Parent = No_Element then Child_Count'Result = 0),
        Nonblocking, Global => null, Use_Formal => null;
```

161.2/5 {*AI12-0112-1*} Child_Count returns the number of child nodes of the node designated by Parent in Container.

162/5
```
function Child_Depth (Parent, Child : Cursor) return Count_Type
   with Pre  => (Parent /= No_Element and then Child /= No_Element)
                   or else raise Constraint_Error,
     Nonblocking, Global => in all, Use_Formal => null;
```

163/5 {*AI05-0136-1*} {*AI05-0262-1*} {*AI12-0112-1*} Child_Depth returns the number of ancestor nodes of Child (including Child itself), up to but not including Parent; Program_Error is propagated if Parent is not an ancestor of Child.

163.a/3 **Ramification:** Program_Error is propagated if Parent and Child are nodes in different containers.

163.b/3 Child_Depth (Root (Some_Tree), Child) + 1 = Depth (Child) as the root is not counted.

163.1/5
```
function Child_Depth (Container : Tree; Parent, Child : Cursor)
   return Count_Type
   with Pre  => ((Parent /= No_Element and then Child /= No_Element)
                   or else raise Constraint_Error) and then
                (Meaningful_For (Container, Parent)
                   or else raise Program_Error) and then

                  Position = Before or else
                  Is_Ancestor_Of (Target, Position, Parent)
                    or else raise Constraint_Error),
        Post => (declare
                    Org_Sub_Count renames
                        Subtree_Node_Count (Source, Position)'Old;
                    Org_Target_Count renames Node_Count (Target)'Old;
                 begin
                   (if not Target'Has_Same_Storage (Source) then
                       Node_Count (Target) = Org_Target_Count +
                          Org_Sub_Count and then
                       Node_Count (Source) = Node_Count (Source)'Old -
                          Org_Sub_Count and then
                       Has_Element (Target, Position)
                    else
                       Target.Parent (Position) = Parent and then
                       Node_Count (Target) = Org_Target_Count));
```

{*AI05-0136-1*} {*AI05-0248-1*} {*AI05-0262-1*} {*AI05-0269-1*} {*AI12-0112-1*} If Source denotes the same object as Target, then: if Position equals Before there is no effect; otherwise, the subtree rooted by the element designated by Position is moved to be a child of Parent. If Parent already has child nodes, then the moved nodes are inserted prior to the node designated by Before, or, if Before equals No_Element, the moved nodes are inserted after the last existing child node of Parent. In each of these cases, Position and the count of Target are unchanged, and the parent of the element designated by Position is set to Parent. 179/5

Reason: We can't allow moving the subtree of Position to a proper descendant node of the subtree, as the descendant node will be part of the subtree being moved. The result would be a circularly linked tree, or one with inaccessible nodes. Thus we have to check Position against Parent, even though such a check is *O*(Depth(Source)). 179.a/3

{*AI05-0136-1*} {*AI05-0248-1*} Otherwise (if Source does not denote the same object as Target), the subtree designated by Position is removed from Source and moved to Target. The subtree is inserted as a child of Parent. If Parent already has child nodes, then the moved nodes are inserted prior to the node designated by Before, or, if Before equals No_Element, the moved nodes are inserted after the last existing child node of Parent. In each of these cases, the count of Target is incremented by Subtree_Node_Count (Position), and the count of Source is decremented by Subtree_Node_Count (Position), Position is updated to represent an element in Target. 180/3

Ramification: If Source is the same as Target, and Position = Before, or Next_Sibling(Position) = Before, Splice_Subtree has no effect, as the subtree does not have to move to meet the postcondition. 180.a/3

180.b/3 We do not allow splicing a subtree that includes a root node, as that would require inserting a node with no value in the middle of the target tree. Splice the children of the root node instead.

180.c/3 For this reason there is no operation to splice an entire tree, as that would necessarily involve splicing a root node.

181/5
```
procedure Splice_Subtree (Container: in out Tree;
                          Parent   : in     Cursor;
                          Before   : in     Cursor;
                          Position : in     Cursor)

If Target_Parent already has child elements, then the moved elements are inserted prior to the node designated by Before, or, if Before equals No_Element, the moved elements are inserted after the last existing child node of Target_Parent. The parent of each moved child element is set to Target_Parent. 188/3

Reason: We can't allow moving the children of Source_Parent to a proper descendant node, as the descendant node will be part of one of the subtrees being moved. 188.a/3

{*AI05-0136-1*} {*AI05-0248-1*} {*AI05-0269-1*} Otherwise (if Source does not denote the same object as Target), the child elements (and the further descendants) of Source_Parent are removed from Source and moved to Target. The child elements are inserted as children of Target_Parent. If Target_Parent already has child elements, then the moved elements are inserted prior to the node designated by Before, or, if Before equals No_Element, the moved elements are inserted after the last existing child node of Target_Parent. In each of these cases, the overall count of Target is incremented by Subtree_Node_Count (Source_Parent)-1, and the overall count of Source is decremented by Subtree_Node_Count (Source_Parent)-1. 189/3

189.a/3 **Ramification:** The node designated by Source_Parent is not moved, thus we never need to update Source_Parent.

189.b/3 Move (Target, Source) could be written Splice_Children (Target, Target.Root, No_Element, Source, Source.Root);

190/5
```
procedure Splice_Children (Container       : in out Tree;
